CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY

OF

UNIVERSAL KNOWLEDGE

NEW EDITION

VOL. VIII

PEASANT TO ROUMELIA

WILLIAM & ROBERT CHAMBERS, LIMITED
LONDON AND EDINBURGH
J. B. LIPPINCOTT COMPANY, PHILADELPHIA
1901

All Rights reserved

The following Articles in this Volume are Copyrighted by J. B. Lippincott Company in the United States of America:

Pennsylvania.
Peru.
Petroleum.
Philadelphia.
Phœnicia.
Phonograph.
Pitt, William.
Pittsburgh.
Poe, Edgar Allan.
Poetry.
Prisons.
Protection.
Rabelais.
Railways.
Rhode Island.
Rifles.
Rocky Mountains.
Roman Catholic Church.

AE
5
C44
v.8

Among the more important articles in this Volume are the following:

Peasant Proprietors.	Jesse Collings, M.P.
Peking	Professor Legge.
Pelasgians; Pluto	F. B. Jevons.
Pelvis	Dr David Hepburn.
Pendulum	R. E. Anderson.
Pennsylvania	Frank B. Greene, M.A.
Pensions (Army)	Lieut.-Col. Dunlop, R.A.
" (Navy)	Capt. Garbett, R.N.
Pentateuch; Peter	Rev. J. Sutherland Black.
Pepys	H. B. Wheatley.
Perfumery	C. A. Piesse.
Periodicals	W. T. Stead.
Persia; Persepolis	Major-Gen. Sir R. Murdoch Smith.
Peru; Pizarro	Sir Clements R. Markham, K.C.B.
Pessimism	Professor W. Caldwell.
Peterborough	H. D. Traill.
Petrarch	Signora Cantagalli.
Petrography, &c.	Professor James Geikie.
Petroleum	Henry C. Folger, Junr.
Poison	Professor Ralph Stockman.
Philadelphia	W. S. Washburn.
Philippine Islands	Professor A. H. Keane.
Philology	John Peile, Litt.D.
Philosophy, &c.	Professor Pringle Pattison.
Phœnicia	Canon Rawlinson.
Phonetics	Dr A. J. Ellis.
Phonograph	Thomas A. Edison.
Phosphorescence	W. E. Hoyle.
Photography	T. C. Hepworth & W. T. Bashford.
Physiology; Plants	Norman Wyld.
Pianoforte	J. F. Rowbotham.
Picts	A. M'Bain.
Pilchard	F. T. Cunningham.
Pindar; Plautus	John Masson.
Pine	W. Sutherland.
Piquet; Poker	Henry Jones ('Cavendish').
Pisciculture	Sir James G. Maitland, Bart.
Pitt	W. E. H. Lecky, M.P.
Pittsburgh	B. C. Jillson, M.D.
Planets; Ptolemy	Rev. E. B. Kirk.
Plato	Professor D. G. Ritchie.
Pleuro-pneumonia	Principal Williams.
Plough; Potato	James MacDonald.
Plutarch	Rev. H. A. Holden, LL.D.
Plymouth	F. N. Worth.
Pneumonia	Dr Lundie.
Poaching	C. N. Johnstone.
Poe, Edgar Allan	Rev. Professor F. M. Bird.
Poetry	Edmund Gosse, LL.D.
Poland	W. R. Morfill.
Polar Exploration	John S. Keltie, LL.D.
Pole, Cardinal	T. G. Law, LL.D.
Police	James Monro, C.B.
Political Economy	T. Kirkup.
Polynesia	Professor A. H. Keane.
Pompeii; Pliny	Dr J. P. Steele.
Poor-laws	W. C. Smith.
Pope	Rev. W. Hunt & F. A. Gasquet, O.S.B.
Pope, Alexander	H. D. Traill.
Positivism	James Oliphant.
Post-office	J. W. Hyde.
Pottery; Ring	James Paton.
Poultry; Pigeon	Edward Brown.
Prayer-book	Bishop Dowden.
Preaching; Philo	Thomas Davidson.
Precedence	Sir J. Balfour Paul.
Pre-Raphaelitism	W. Holman Hunt.
Printing	John Southward.
Prior; Praed	Austin Dobson.
Prisons	Sir E. F. Du Cane, K.C.B.
Privy-council	A. Wood Renton.
Probabilities	R. E. Anderson.
Profit-sharing	Robert Cochrane.
Protection	W. Draper Lewis.
Protoplasm	J. A. Thomson.
Provençal	A. P. Goudy.
Proverbs; Quevedo	John Ormsby.
Prussia	Findlay Muirhead.
Psalms	Professor T. K. Cheyne.
Psychology	Professor Sorley.
Puerperal Fever	Dr Milne Murray.
Pugilism	Henry Tinson.
Pusey	Rev. J. C. Johnston.
Pyæmia	Professor Alex. Napier.
Pyramid	Stanley Lane-Poole.
Quaternions	Professor Knott.
Quebec	Dr Stewart & J. G. Colmer, C.M.G.
Queensland	W. Senior.
Quito	W. Dundas Walker.
Rabelais	Sir Walter Besant.
Raeburn; Reynolds	J. M. Gray.
Railways	E. M'Dermott, of *Railway News*.
Rain	Dr Buchan.
Rainbow	W. T. Omond.
Raleigh; Racine	Thomas Davidson.
Raphael	Sir Joseph Crowe, C.B.
Reade, Charles	F. Hindes Groome.
Records; Registers	Walter Rye.
Red Sea	Sir John Murray.
Reflection	Dr Alfred Daniell.
Reformation; Renan	P. Hume Brown.
Reformatories	Sir E. F. Du Cane, K.C.B.
Refraction	Dr Alfred Daniell.
Registration	Francis Watt.
Religion	Professor Flint.
Rembrandt	P. G. Hamerton.
Representation	Thomas Raleigh.
Reproduction	J. A. Thomson.
Respiration	Norman Wyld.
Restoration	Thackeray Turner.
Revelation	Rev. J. Sutherland Black, LL.D.
Revolver	W. W. Greener.
Reynard the Fox	J. T. Bealby.
Richardson, Samuel	Austin Dobson.
Richter; Reuter	J. T. Bealby.
Riding and Driving	Captain Hayes.
Rifles	Major-General Areuthnot.
Right-handedness	James Shaw.
Right of Way	C. E. W. Macpherson.
River	Dr Hugh R. Mill.
Rodney	Professor J. K. Laughton.
Rogers	F. Hindes Groome.
Roman Catholicism	Rev. W. L. Gildea, D.D.
Romances; Roland	John Ormsby.
Rome (Topography)	Canon Isaac Taylor.
" (History)	Dr J. P. Steele.
Rose	R. D. Blackmore.
Rossetti	W. M. Rossetti.
Rossini	Colin Stalker.
Roumania	James Samuelson.

The Publishers beg to tender their thanks, for revising the articles 'Penance' and 'Roman Catholic Church,' to His Eminence Cardinal Manning; for 'Pittsburgh,' to Mr Andrew Carnegie; for 'F. W. Robertson,' to Rev. Stopford A. Brooke; for 'Rosmini,' to Father Lockhart; for 'Profit-sharing,' to Mr Alfred Dolge; for 'Positivism,' to Mr Frederic Harrison; for 'Rochester,' to Prebendary Levett; for 'Peterhead,' to Sir John Coode; and to the town-clerks of Peterborough, Preston, Rochdale, Rotherham, &c.

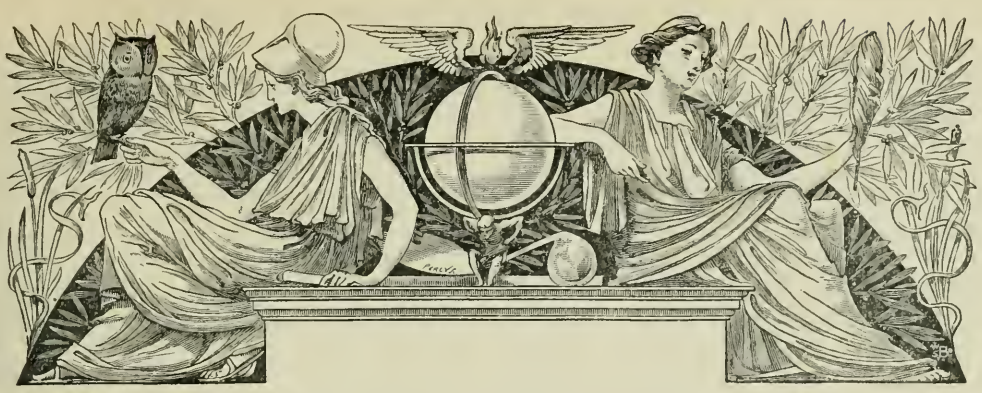
ROMAN EMPIRE.....792



CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Peasant Proprietorship is a system of cultivation of small holdings of land by occupiers who own the land, or hold it on some secure or permanent tenure. Perhaps there is no question on which there is a greater diversity of opinion. On the one hand the small cultivator is held up as a pattern of industry, thrift, and prosperity, and on the other as an example of unceasing toil and miserable failure.

Arthur Young held that the best system of agriculture was that which secured the largest amount of produce from the land. It is evident, however, that another consideration of great importance must be taken into account—viz. the numbers, quality, and condition of those engaged in tilling the soil. Though nations might attain to brilliant positions by trade, commerce, and the accumulation of wealth, yet the permanent strength, the solidity, and resisting power of a country must closely depend on the number and condition of its rural population. Hence if it could be proved that vast areas of land could be cultivated at the greatest money profit, by means of machinery and a handful of labourers, yet such a method of cultivation would be adverse to the real interests of the nation as a whole.

There is substantial evidence, however, that small holdings of land are more productive in proportion than large farms, and that they are specially adapted to the production of certain kinds of food. It is from these causes that the rent value and purchase price of the smaller holdings in continental countries are so much higher than are found to obtain with the larger farms of Great Britain. It is frequently quoted in opposition to this view that the yield of corn per acre is much greater in England than on the Continent. This comparison, however, is of little value from the fact that the average of continental production is much lowered through the low yields of poor land, hillsides, and wastes, which, if in England, would not be cultivated at all. The evidence of the Royal Commission on Agriculture (1880) shows that the vast majority of holdings in the Netherlands are from 10 to 60 acres, held for the most part by cultivating owners, and that the small and medium-sized farms are generally the best cultivated and managed. Mr Jenkins, the assistant commissioner, gave many examples of what he terms 'intensive' cultivation in Holland. One of these is that of a man who owned 22 acres of land, and rented 10 acres more. He had thirty milking cows in the fields, and ten feeding beasts in the stall. He fed every year thirty beasts besides his own cast cows, and spent above £600 per annum for food, principally for winter keep.

Belgium is rather a country of small cultivators than of peasant proprietors. If we leave out of account the owners of very small plots of land, it is the small tenant-farmer who is the most important element in Belgian agriculture. In spite, however, of excessive rents, the insecurity and other drawbacks of tenancies as compared with ownership, Belgium is a striking example of the advantages of *la petite culture*. M. de Laveleye states that Belgium is the best cultivated and the most productive country in the world; and refers to Flanders, with land naturally the worst in Europe, as a marvellous triumph of care, industry, and forethought on the part of the cultivators. According to the report above quoted, the available supply of milk and its products per head of the population is in Belgium about twice as great as that in Great Britain. In most districts in Belgium the labourer is a *petit cultivateur*—i.e. while hiring himself out as a labourer, he cultivates and often owns a piece of land stocked with rabbits, pigs, poultry, goats, and sometimes one or a couple of cows. A man of this class in the Ardennes, who was working with his son for a farmer at five francs per day, was found on inquiry by the present writer to be the owner of a cottage with 6 acres of land, two cows, and other smaller

stock. This man is a type of a most numerous class whose aim is to be become small farmers, and who, with that end in view, work hard and practise the severest thrift and perseverance.

In Great Britain the amount of stock per acre carried on small holdings is larger—with the exception of sheep—than that carried on a similar area of land in large farms. Tables compiled by the writer from the agricultural returns of Great Britain, and printed in the evidence given before the Select Committee on Small Holdings (1889), show that the area of land in Great Britain cultivated in small holdings of 1 acre to 100 acres is about the same as the area cultivated in large farms of 300 acres and upwards, the area being about 9¼ and 9½ million acres respectively. The tables show that the small holdings carry 511,038 horses, the large farms 314,016: cows and other cattle 2,660,281 as against 1,227,904; pigs 1,178,500 as against 383,626. Only in sheep is the advantage shown to be with the large farms. It frequently happens that cases showing the failure of *petite culture* refer really to small cultivators who hold their land on a yearly tenancy or some other uncertain tenure, a class altogether distinct from and lacking the essential conditions of peasant proprietors. The great prosperity of agriculture in Denmark, and the large and increasing exports of butter, eggs, cattle, pigs, &c. from that country are due to the fact that the great bulk of the land is cultivated by owners, mainly by peasant proprietors of farms from 25 to 125 acres. Mr Jenkins gives interesting examples, not exceptional, of prosperous highly cultivated peasant farms in Denmark. One small owner of 50 acres of land kept eighteen cows, fed eighteen pigs annually, and had two horses to work the arable land. The whole family was employed on the farm or in the dairy. The dairy, though small, 12 by 14 feet, was a perfect sight for order, cleanliness, and for the complete though inexpensive character of the arrangements and appliances. The majority of the agricultural labourers in Denmark possess a cottage with a few acres of land, either his own or on lease. In Germany the agrarian reforms inaugurated by Stein and Hardenberg early in the 19th century, and continued up to recent date, for the promotion of cultivating ownership in land, were undoubtedly the groundwork of the strength and solidity of the German nation.

In direct connection with the subject of peasant proprietorship is the fact of Britain's great and increasing dependence on foreign countries for a supply of the smaller articles of food. Besides fruit, vegetables, honey, flowers, &c., the importation of which is yearly increasing, the value of the following articles in pounds sterling imported in 1889 was as follows: Cheese above 4½ million; butter above 10¼ million; margarine above 3½ million; lard above 2 million; poultry, game, and rabbits above 3¼ million; bacon and hams above 9¾ million; pork, potatoes, and onions above 2 million; eggs above 3 million. This gives the enormous aggregate value of 36 million sterling paid annually to the foreigner for these smaller articles of food, for the production of which the soil and climate of England are for the most part specially fitted. In the face of chronic complaints of agricultural depression, this great volume of trade is allowed to pass into the hands of the small cultivator abroad. The reason is that the system of large farming is not adapted to the supply of these articles. The large farmer who raises corn and cattle cannot successfully compete with the small grower who is accustomed to minute and intensive cultivation. Peasant proprietorship is a separate and distinct business. The conditions of its success are close personal attention, hard work, and the strictest frugality. The peasant cultivator employs but little hired labour, every member of the family doing something useful on the little holding. The system develops a handiness, a fertility of resources, an adaptation of means to ends, and an incessant industry, qualities hardly to be expected in connection with hired labour. As owner of his little holding the peasant proprietor has no restrictions as to cropping or methods of cultivation. He has no doubts about compensation for unexhausted manures and improvements, and no uncertainty as to tenure. As a small owner who for many years has lived on and successfully cultivated a few acres of land remarked to the present writer—'The more I care for and work my land the more it gives me back; my little farm is my bank in which I put my labour and savings, which it pays me back with good interest.' It is often said that thrift, prudence, and perseverance are peculiar to the peasant proprietor on the Continent, and are the cause of his success. The history of peasant proprietorship, however, shows that these qualities are the result and not the cause of cultivating ownership. Improvident habits, early marriages, and little thought for the morrow are the too frequent accompaniments of a condition in which there is no prospect in life beyond that of a mere wage-receiver. The great secret of success of peasant proprietorship is summed up by Adam Smith in a striking passage in his *Wealth of Nations*: 'A small proprietor who knows every part of his little territory, who views it with all the affection which property, especially small property, naturally inspires, and who upon that account takes pleasure not only in cultivating but in adorning it, is generally of all improvers the most industrious, the most intelligent, and the most successful.' The two great drawbacks of peasant proprietorship are excessive subdivision and the unlimited power of mortgage. The land-hunger—especially in France—is so great that the proprietor of a few acres will submit to any privation to save money, and will borrow at any rate, in order to acquire more land. The money-lender on the Continent, like the 'gombeen' man in Ireland, is the chief cause of trouble and difficulty to the small cultivator. The creation of a peasant proprietorship in Great Britain, though much discussed, has not till recently been seriously entertained as a practical question. In 1889 the government appointed a Select Committee on Small Holdings, and the evidence contains practical information on the various aspects of peasant proprietorship, and on the applicability of the system to Great Britain. The committee in their Report (1890) unanimously recommend that facilities should be given for the creation of small holdings, and they adopt the principles of Mr Jesse Collings' Small Holdings Bill. The general provisions of this bill are as follows: Local authorities are empowered by moneys borrowed for that purpose from the state, to acquire land and to sell the same in small holdings not exceeding 50 acres each. Purchasers are required to pay down as proof of their *bona fides* a portion not exceeding one-fourth or one-fifth of the purchase-money. A part of the balance is to be paid off by annual payments, but the remainder—a small proportion of the original cost—is to remain at a perpetual feu or quit-rent. This provision, while it protects the small holder—to a great extent—from the money-lender, at the same time makes the terms of purchase as easy as possible. It also enables the local authority to enforce the conditions provided against subletting and subdivision. The local authorities are further empowered to *let* land on favourable conditions in small holdings not exceeding 10 acres each. The report of the Select Committee declares that the extension of small ownerships 'is a matter of national importance both in the interests of the rural population, and

also as adding to the security of property generally.' The committee recommend that a sum not exceeding in the first instance five millions sterling should be devoted to the experiment, and 'earnestly hope that no time will be lost in introducing legislation to give effect to their recommendations.' This report, followed by the announcement of legislation on the subject in the Queen's speech of 1890, and the acceptance by the government in 1891 of the second reading of the Small Holdings Bill referred to, may together be taken as the first practical steps towards the creation of a peasant proprietorship in Great Britain. See also ALLOTMENTS.

See, besides the reports cited above, that from H.M. representatives abroad, *On the Tenure of Land in the several Countries in Europe* (1869); Laveleye's works on the rural economy of Belgium (new ed. 1875) and the Netherlands (1864); Lavergne, *Economie Rurale de la France* (4th ed. 1877); and W. T. Thornton's *Plea for Peasant Proprietors* (new ed. 1874).

Peasant War (*Bauernkrieg*), a great insurrection of the German peasantry which broke out in the beginning of the year 1525. The oppression of the peasants had gradually increased in severity as the nobility became more extravagant and the clergy more sensual and degenerate. The example of Switzerland encouraged the hope of success, and from 1431 to 1517 there were risings amongst the peasants of the south and west of Germany. A peasant rebellion took place in the Rhine countries in 1502, and another in Würtemberg, in 1514, both of which were put down without any abatement of grievances. The Reformation, by stirring up the desire of freedom, must be reckoned amongst the causes of the great insurrection itself; although Luther, Melanchthon, and the other leading reformers, whilst urging the nobles to justice and humanity, strongly reprobated the violent proceedings of the peasants. The Anabaptists, however, encouraged them, and peasant insurrections, quickly suppressed, took place in 1522 and 1523. In January 1525 the peasantry of the abbacy of Kempten suddenly assailed and plundered the convent. This proved the signal for a rising of the peasants throughout the south of Germany. Many of the princes and nobles at first regarded the insurrection with complacency, because it was directed in the first instance chiefly against the ecclesiastical lords; some, too, because it seemed to set bounds to the increase of Austrian power. But the Archduke Ferdinand hastened to raise an army, and entrusted the command of it to Von Waldburg, a man of stern and unscrupulous character. Von Waldburg defeated and destroyed some large bodies of peasants, but was himself defeated by them on the 22d of April. Meanwhile the insurrection extended, and a number of towns took part in it, as Heilbronn, Mühlhausen, Fulda, Frankfort, &c., but there was a total want of organisation and co-operation. On 25th March 1525 there appeared in Upper Swabia a manifesto, in which the insurgents demanded the free election of their parish clergy; the appropriation of the tithes, after maintenance of the parish clergy, to the support of the poor; the abolition of serfdom; the restoration to the community of forests, fields, and meadows which the secular and ecclesiastical lords had appropriated; release from arbitrary augmentation and multiplication of services, duties, and rents; the equal administration of justice; and the abolition of some of the most odious exactions of the clergy. The conduct of the insurgents was not, however, in accordance with the moderation of their demands. Their many separate bands destroyed convents and castles (more than 1000 in all), murdered, pillaged, and were guilty of the greatest excesses. A number of princes and knights concluded treaties with the peasants, conceding their principal demands. The siege of Marienberg, near Würzburg, gave time to their enemies to strengthen their forces. Götz von Berlichingen (q.v.) was one of the captains of the besieging peasants, who, he afterwards maintained, had forced him to lead them. In May and June 1525 the peasants sustained a number of severe defeats; and the Landgrave Philip of Hesse, the Saxon Dukes, the electors of the Palatinate and Treves, and Frundsberg were successful farther north. The peasants were everywhere treated with terrible cruelty; more than 130,000 were killed in Upper Germany alone. Multitudes were hanged in the streets, and many were put to death with the greatest tortures. Würzburg and other towns which had joined them suffered the terrible revenge of the victors. It is supposed that more than 150,000 persons lost their lives in the Peasant War. Flourishing and populous districts were desolated. The lot of the defeated insurgents became harder than ever, and many burdens of the peasantry originated at this period. The cause of the Reformation and of German national life also was very injuriously affected. Similar peasant insurrections in other countries are treated of under TYLER, CADE, KET, JACQUERIE, SPARTACUS.

See works by Jörg (1851), Cornelius (1861), Baumann (1877), Fries (1883), Hartfelder (1884; 2d ed. 1889); the histories of Germany; and works cited at LUTHER, &c.

Peastone, or PISOLITE, a coarse variety of Oolite (q.v.).

Peat, a substance formed by the decomposition of plants amidst much moisture, as in marshes and morasses, and sometimes described as a kind of humus or soil, formed by the accumulation of the remains of mosses and other marsh-plants. The remains of the plants are often so well preserved in it that the species can be easily distinguished. Reeds, rushes, and other aquatic plants may usually be traced in peat, and stems of heath are often abundant in it; but it chiefly consists in the northern parts of the world of different species of *Sphagnum* or Bog-moss (see BOG-PLANTS). Mosses of this genus grow in very wet situations, and throw out new shoots in their upper parts whilst their lower parts are decaying and being converted into peat; so that shallow pools are gradually changed into bogs. Stools and trunks of trees often occur under peat in the British Islands and in north-western Europe generally. And not only so, but similar stools and trunks frequently are met with occupying a middle position in many peat-bogs—i.e. resting on peat and covered by a variable thickness of the same accumulation. It cannot be doubted that the overturning of trees, whether by natural causes or by man's hand, would in many cases impede surface drainage, and so eventually give rise to the formation of bogs. But there is reason to suspect that the succession of 'buried forests' and peat so frequently seen in the bogs of north-western Europe points to climatic changes (see POST-GLACIAL SYSTEM). Peat is vegetable matter more or less decomposed, and passes by insensible degrees into Lignite (q.v.). The less perfectly decomposed peat is generally of a brown colour; that which is more perfectly decomposed is often nearly black. Moist peat possesses a decided and powerful antiseptic property, which is attributed to the presence of gallic acid and tannin, and is manifested in the perfect preservation not only of ancient trees and of leaves, fruits, &c., but sometimes even of animal bodies. Thus, in some instances human bodies have been found perfectly preserved in peat after the lapse of centuries.

The formation of peat takes place only in the colder parts of the world. In warm regions the

decay of vegetable substances after life has ceased is too rapid. The surface covered by peat is very extensive in all temperate regions. In England it is considerable; it is greater in Scotland, and very great in Ireland. Some large peat-bogs occur in the south of Europe, even near the sea, and in more northern regions the mosses or bogs are still more extensive; they occur also in the northern United States, but more extensively in Canada and Newfoundland. For their physical characters and the mode of reclaiming them, see BOG, and WASTE LANDS. Mere peat is not a good soil, even when sufficiently drained, but by the application of lime, marl, &c. it is soon converted into valuable land, yielding excellent crops. A mixture of peat is often of benefit to soils otherwise poor; and for many shrubs, as rhododendrons, kalmias, whortleberries, &c., no soil is so suitable as one largely composed of peat.

Peat is the ordinary fuel of great part of Ireland, and is still much in request in the hillier parts of Scotland and England. In Holland, Denmark, and parts of north Germany it is also in use for the same purpose. Peat is a light and bulky kind of fuel, and cannot be conveyed to considerable distances without too great expense. Efforts have, however, been made to render it more generally useful, and so to promote the reclaiming of bogs, by compressing it until its specific gravity is nearly equal to that of coal. For this purpose it is first reduced to a pulp. But the process has not yet been advantageously prosecuted on an extensive scale, though numerous machines for the purpose have been patented in Germany and in the United States. Peat-charcoal, made from uncompressed peat, is very light and inflammable, and therefore unsuitable for many purposes, but for others it is particularly adapted, and no kind of charcoal excels it in antiseptic and deodorising properties. Peat-charcoal is highly esteemed for the smelting of iron and for working and tempering the finer kinds of cutlery. Charcoal made from compressed peat is in density superior to wood-charcoal, and is capable of being used as coke. But the conversion of peat into charcoal has not proved remunerative; and the attempts to obtain valuable products (pyroligneous acid, ammonia, inflammable oils, burning gas, tar, &c.) from its destructive distillation have been similarly unsuccessful.

Peat, specially prepared, is very serviceable for horses' bedding, &c. As antiseptic, it has been used for laying on wounds. Flower-pots are sometimes made of peat; it is easy to transplant flowers growing in them without loosening the earth from the roots, the pot being readily cut to pieces; and liquid manure applied outside finds its way to the roots.

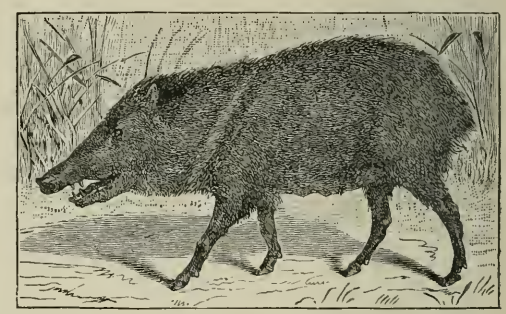
See Rennie, *Essays on the Natural History and Origin of Peat-moss* (1810); Aiton, *Treatise on the Origin, Qualities, and Cultivation of Moss-earth* (1811); Steele, *Natural and Agricultural History of Peat-moss or Turf-bog* (1826); a parliamentary *Report on the Destructive Distillation of Peat* (1851); Rev. J. Peter, *The Peat Mosses of Buchan* (1875); J. Geikie, *Prehistoric Europe*.

Pebble (probably allied to *bubble*, from the sound of water running among stones), a small, round, water-worn stone of any kind; but with jewellers sometimes an agate—agates being often found as loose pebbles in streams, and those of Scotland in particular being popularly designated *Scotch Pebbles*. Hence the name has come even to be extended to rock-crystal when not in the crystalline form. Deposits of pebbles (in the sense of water-worn stones) occur among the rocks of all periods, but the pebbles are seldom loose: they are generally cemented together by iron, lime, or silica, forming a pudding-stone of greater or less hardness (see CONGLOMERATE). Single pebbles are sometimes found in deposits which have been formed in perfectly still water, as in chalk and fine silt. They must have been floated to their places entangled in the roots of trees, or attached to the roots of large buoyant seaweeds.—BRAZILIAN PEBBLES (so called from Brazil having been long famous for the purity of its rock-crystal) are very pure pieces of Rock-crystal (q.v.) used by opticians for making the lenses of spectacles, &c.

Pebrine. See PASTEUR, SILK.

Pecan. See HICKORY.

Peccary (*Dicotyles*), a genus of the family Suidæ, containing at least two species. They have fewer teeth (thirty-eight) than the ordinary swine (forty-four), and a very short tail. The name Dicotyles is derived from a gland upon the back, almost corresponding in position to the navel below. *D. torquatus* is found from Arkansas to Patagonia, and is about 3 feet long; but the larger and fiercer *D. labiatus* only ranges from



Peccary (*Dicotyles labiatus*).

Central America to southern Brazil. The latter is exceptionally pugnacious, and, as it goes about commonly in herds, it is extremely dangerous to meet with. Even the jagnar is said to retire before several of these animals when banded together. Both species, which freely breed together, are usually to be seen at the Zoological Gardens in London.

Pe-chi-li, GULF OF, a land-locked extension of the Yellow Sea (q.v.), between the base of the Corean peninsula and the Chinese province of Shan-tung, into which the Pei-ho (q.v.) discharges.

Peck, a measure of capacity for dry goods, such as grain, fruit, &c., used in Britain, and equivalent to two imperial gallons, or 554·548 cubic inches. It is thus the fourth part of a Bushel (q.v.). The old Scotch peck, the sixteenth part of a boll, when of wheat was slightly less than the imperial peck, but when of barley was equal to about 1·456 of it.

Pecock, REGINALD, author of *The Repressor of Over-Much Blaming of the Clergy*, was most probably born in Wales; was a Fellow of Oriel College, Oxford, in 1417, and was ordained acolyte and sub-deacon in 1420, proceeding to deacon's and priest's orders in the two following years. His preferments were the mastership of Whittington College, London, together with the rectory of St Michael in Riola; the bishopric of St Asaph's, from Duke Humphrey of Gloucester in 1444, when he also received his degree of Doctor of Divinity, and of Chichester, through the patronage of the ill-fated William de la Pole, Duke of Suffolk, in 1450. A student of great learning and industry, he plunged eagerly into the controversies of the day, and compiled many treatises, of which the *Donet* (*c.* 1440), on the main truths of Christianity, and his practical *Treatise on Faith* (*c.* 1456), written for the Lollards, are still extant.

In the latter he gives up infallible authority in the church, makes faith a matter of probability rather than of knowledge, lays a broad foundation for a really rational piety, and makes a noble approximation to the doctrine of religious toleration. The object of his *Repressor* (*c.* 1455) was to promote the peace of the church by plain arguments against Lollardy, written in the mother-tongue. He maintained that bishops had higher duties than mere preaching, and strove with great patience and clear logic to demonstrate the reasonableness of those doctrines and ordinances of the church which the Lollards rejected as not founded on Scripture. Of a liberal and tolerant spirit far before his time, Pecock pointed out with much point and originality the teaching of natural religion about man's moral duties, asserting that the judgment of reason must not be overruled and twisted into conformity with Scripture, which rather confirms than serves as the authority for the light of nature. In his argument that Scripture pre-supposes a knowledge of the moral virtues, and that its special object is to make known those truths which reason could not have discovered, he is distinctly the forerunner of the great Hooker. His attack on the Donation of Constantine is an admirable piece of reasoning, and his argument that experience shows that there is no subject on which men are more likely to err than the interpretation of Scripture deals a deadly blow to the bibliolatry of Lollardy and Protestantism. Pecock's philosophic breadth and independence of judgment brought upon him the suspicions of the church, and especially of the friars, whom he had stigmatised as 'pulpit bawlers.' The storm of opposition that had long been gathering burst upon his head at a council held at Westminster in 1457. He was hotly denounced for having written in English, and for making reason paramount even to the authority of the old doctors, while many slanderous and baseless charges besides were heaped upon his head. He was summoned before Archbishop Bourchier at Lambeth, where his writings were subjected to examination by twenty-four doctors. In the end he was condemned by the archbishop as a heretic whose doctrines were contrary to St Augustine, St Jerome, and St Gregory, and the cruel alternative was put before him, to abjure his errors or be burned. He elected to abjure, made confession of many errors and heresies of which he had never been guilty, and with his own hands delivered to the executioner his three folios and eleven quartos for the flames. Against the further sentence that he should be deprived of his see he appealed to Rome, and the pope indeed commanded him to be reinstated, but he was prevailed upon to resign his bishopric into the hands of the king. The rest of his days he spent in the abbey of Thorney in Cambridgeshire. Forty pounds a year was allowed for his maintenance; he was to have the service of an attendant, somewhat liberal diet, and a private chamber with a chimney and a passage leading from it which gave a sight of an altar and allowed him to hear mass. He was denied writing materials, and his books were but five—a breviary, a mass-book, a psalter, a legendary, and a Bible. He died about 1460.

See the article LOLLARDS; also James Gairdner's essays on 'The Lollards,' in *Studies in English History* (1881); the Introduction to Churchill Babington's edition of the *Repressor* in the Rolls series (2 vols. 1860); and the *Life* by John Lewis (1774; reprinted, Oxford, 1820).

Pecos, a river of New Mexico and Texas, flows some 800 miles SSE. to the Rio Grande.

Pecten. See SCALLOP.

Pectic Acid and **Pectin.** See FRUIT, Vol. V. p. 21.

Peculiar. See BENEFICE.

Peculiar People, a sect of Faith-healers (q.v.), founded in London in 1838. They reject medical aid in cases of disease, although not in surgical cases, and rely on anointing with oil by the elders, and on unceasing prayer, with patient nursing. They have their own collection of hymns, usually select their preachers from among the elders, and baptise their children when they are considered old enough to understand the ceremony and to express consent. Their communities are not numerous, and the members are nearly all very poor working-folk; but they bear a high character for morality, honesty, and Christian charity.

Pedestrianism. See ATHLETIC SPORTS.

Pedicellariæ, very remarkable minute structures on the skin of sea-urchins and starfish, having the form of a stalk with a three-bladed or two-bladed snapping forceps at the summit. They take hold of algæ preparatory to the application of the suctorial feet, and probably help likewise to keep the surface of the echinoderm clean.

Pedicularis, a genus of herbs of the natural order Scrophulariaceæ, some of which have rather large and finely-coloured flowers. Two species, *P. palustris* and *P. sylvatica*, are natives of Britain, common in wet grounds. Both have received the name of Lousewort, the English equivalent of 'pedicularis,' from their supposed influence in producing the lousy disease in sheep—an influence purely imaginary. Their acridity renders them obnoxious to sheep; but cattle, goats, and swine eat them. Continental Europe and the northern parts of Asia produce many other species, and some are found in North America. *P. sceptrum*, or King Charles's Sceptre, is one of the principal ornaments of marshy grounds in the most northern countries of Europe. *P. sylvatica* is said to be astringent and serviceable in stopping hæmorrhage; and applied externally it helps to cleanse ulcers.

Lousewort (*Pedicularis palustris*).

Pedigree (possibly from *pied de grue*, 'crane's foot,' from the slender lines used in drawing pedigrees), a tabular view of the members of a particular family, with the relations in which they stand to each other, accompanied or unaccompanied by a notice of the chief events in the life of each, with their dates, and the evidence of the facts stated. Pedigrees are indispensable aids to the student of history. The materials to be used in the formation of a pedigree are notes of the facts to be set forth, and a recognised series of signs and abbreviations. These notes comprise the name of every person who is to appear in the pedigree, with such dates and circumstances as it may be considered desirable to record. Among the commonest abbreviations are *dau.*, for daughter of; *s. and h.*, son and heir of; *coh.*, coheir of; *w.*, wife of; *s. p.* (*sine prole*), without issue; *v. p.* (*vitâ patris*), in his father's lifetime; *b.*, born; *d.*, died; *dep.*, deposed; K., king; E., earl, &c. The sign = placed between

two names indicates that they were husband and wife; ∓ indicates that they had children; ↓ under a name signifies that the person had children. Men are frequently indicated by small squares, women by circles or lozenges. All persons of the same generation are to be kept in the same horizontal line; and the main line of descent is, wherever possible, to be indicated by keeping the successive names in a vertical column. Continuous lines indicate the succession of the different generations. The members of the same family are generally arranged in their order of birth in two groups—the sons first, and then the daughters; but where the same father or mother has children by more than one marriage, the children of each marriage ought to form distinct groups. The actual arrangement, however, of a pedigree must always depend on the leading object which it is intended to illustrate. Specimens may be seen in the articles BONAPARTE and BOURBON.

Tabular genealogies, generally brief, and meant to illustrate some particular claim of right, are found among the records, public and private, of the early middle ages; but after the incorporation of the English Heralds' College far more attention was devoted to the compilation of pedigrees of families, more particularly with reference to their claims to dignities and heraldic insignia. In the course of the 16th century the heralds obtained copies of all such accounts of the English families of any distinction as could be supplied to them, and entered them in the books which contain the records of their official proceedings. Royal commissions were issued till 1704 to the two provincial kings-of-arms, empowering them to visit in turn the several counties of England, in order to collect from the principal persons of each county an account of the changes which had taken place in their respective families in the interval since the last preceding visitation, and to inquire what account could be given of themselves by families who had stepped into the rank of gentry, or had become settled in the county since that period. The register-books kept by the heralds and their assistants contain the pedigrees and arms collected in the course of the visitations, with the signatures of the heads of the families. See HERALDRY, Vol. V. p. 660.

In Scotland, in the absence of the regular system of visitations which prevailed in England, there is a great deal of evidence regarding the pedigrees of the historical families of the country scattered here and there in public and private collections, including the Advocates' Library and Lyon Office. A register of genealogies exists in the Lyon Office, in which the pedigrees of applicants, after being proved to the satisfaction of the heraldic authorities, are inserted with the accompanying evidence; and the Register of Arms contains much valuable information. To what extent the register of genealogies in the Lyon Office may be admitted as a probative document, conclusive of the facts which it sets forth, has not been ascertained by actual decision; but there can be no doubt that, in questions both as to property and honours, it would be regarded as a most important adminicle of proof.

Burnett, *Popular Genealogist, or the Art of Pedigree-making* (Edin. 1865); Rye, *Records and Record Searching* (1888); Whitmore, *The American Genealogist* (1862; 2d ed. 1875); Durrie, *Bibliographia Genealogica Americana* (1868).

Pediment. the triangular space over the portico at the ends of the roof of classic buildings. It may be called the gable of classic buildings, and is frequently enriched with sculpture, for which it forms a fine setting. See GREEK ARCHITECTURE.

Pedlars. See HAWKERS.

Pedo'meter. an instrument for measuring walking distances. It has a dial which records revolutions of the mechanism; and the mechanism is generally actuated by the relative movement of a comparatively heavy suspended mass attendant on each step, though in some forms it is driven by a cord connected with the foot. In all cases the thing measured is the number of steps rather than the distance walked; and the user must find the true meaning of the readings of the apparatus as applied to his own walking.—An instrument attached to the wheel of a carriage so as to mark the number of revolutions of the wheel and so the distance traversed is called *hodometer* or *odometer* (Gr. *hodos*, 'way,' and *metron*, 'measure'). This is usually a train of wheelwork attached to the axle of the carriage, and communicating motion to an index on a dial. A similar instrument, called a cyclometer, is attached to bicycles and tricycles. The name odometer is also given to a wheel used by surveyors, which records the distances in miles or rods.

Pedro I., emperor of Brazil (1798–1822), second son of John VI. of Portugal, fled to Brazil with his parents on Napoleon's invasion of Portugal, and became prince-regent of Brazil on his father's return to Portugal. For the proclamation of Brazilian independence and subsequent history, see BRAZIL.—PEDRO II., his son, born 2d December 1825, became king in 1831 on his father's abdication, was declared of age in 1840, and, distinguished by his love of learning and simple scholarly tastes, reigned over Brazil in peace until the sudden revolution of November 15, 1889, compelled him to withdraw to Europe, where he lived, mainly in France, Brazil becoming a republic under the name of 'United States of Brazil.' He died at Paris, 5th December 1891. See Life by Mossé (1889).

Pedro the Cruel, king of Castile and Leon, was the only legitimate son of Alfonso XI., and was born at Burgos, 30th August 1334. On his father's death (1350) Pedro succeeded to the throne without opposition, but left the whole exercise of power to his mother, Donna Maria of Portugal, and Albuquerque, his father's prime-minister and chancellor. But by the instigation of his mistress (afterwards his queen), Marie de Padilla, Pedro emancipated himself in 1353 from the guidance of the queen-mother. He now obtained exceeding popularity; but the strict justice with which he decided all causes between the rich and poor, the clergy and the laity, combined with a haughty and imperious carriage towards them, alienated from him the nobles and clergy. The plottings of Albuquerque, who had fled to Portugal, having culminated (1354) in a revolt in Estremadura, Pedro marched against the rebels, but was betrayed by his brother Henry and taken prisoner. Escaping, he found himself speedily at the head of a powerful army, with which, despite the excommunication of the pope, he speedily reduced his opponents to submission. But having been betrayed by his relatives, and even by his mother, he became suspicious of every one; and the rest of his reign was devoted to the destruction of the power of the great vassals, the establishment of his own authority on the ruins of their feudal tyranny, and long-continued and bloody wars with the kingdoms of Aragon and Granada. He owes the epithet Cruel mainly to the murder of his brother Don Fadrique in 1358. But he is still often called in Spain 'the Justiciary,' from remembrance of his better qualities. The

people were in general well and justly governed, but the heavy taxes imposed to maintain the cost of his long wars with Aragon and Granada dissipated his popularity. Henry, who had fled to France, now seizing the favourable opportunity, returned (1366) at the head of a body of exiles, backed by Bertrand du Guesclin (q.v.) with an army of mercenaries, and aided by Aragon, France, and the pope. Pedro, however, by great promises of territory and money, prevailed upon Edward the Black Prince to espouse his cause. Edward invaded Castile in the spring of 1367, totally defeated Henry and Du Guesclin at Navarrete (13th April), taking the latter prisoner. But the king disgusted his chivalrous ally by his cruelty to the vanquished, and paid no heed to his remonstrances; Edward accordingly repassed the Pyrenees, and left the misguided monarch to his fate. The whole kingdom groaned under his cruelties; rebellions broke out everywhere; and, in autumn 1367, Henry returned with 400 lances, the people immediately flocking to his standard. Pedro's scanty and ill-disciplined forces, including many Saracens, were routed at Montiel (14th March 1369), and himself compelled to retire for safety within the town, whence he was treacherously decoyed and captured by Du Guesclin. He was carried to a tent, where a single combat took place between him and Henry, in which Pedro was slain, 23d March 1369. See Prosper Mérimée's monograph (1848; 2d ed. 1865; Eng. trans. 1849).

Peduncle. See FLOWER.

Peeblesshire, or TWEEDDALE, a southern county of Scotland, bounded by Edinburgh, Selkirk, Dumfries, and Lanark shires. Irregular in outline, it has a maximum length and breadth of 29 and 21 miles, and an area of 356 sq. m. or 227,869 acres. The Tweed, rising in the extreme south, winds 36 miles north-north-eastward and eastward, descending therein from 1500 to 450 feet; and from it the surface rises into big, round, grassy hills—Windlestraw Law (2161 feet), Minchmoor (1856), Hartfell (2651), Broad Law (2754), &c. Among the Tweed's numberless affluents are Talla, Biggar, Lyne, Manor, Eddleston, Leithen, and Quair Waters; and St Mary's Loch touches the southern boundary. Less than one-fifteenth of the entire area is under corn and root crops; but nearly 200,000 sheep graze on the hillsides. The antiquities include over fifty hill-forts, the 'Romanno terraces,' a Roman camp at Lyne, the ruined castles of Neidpath and Drochil, and the old mansion of Traquair; whilst 4 miles SW. of Peebles is the cottage of Davie Ritchie, the 'Black Dwarf' (1740–1811). Peebles and Innerleithen are the only towns. The county unites with Selkirkshire to return one member. Pop. (1801) 8735; (1841) 10,499; (1881) 13,822; (1891) 14,761.

PEEBLES, the pleasant county town, stands on the left bank of the Tweed, 22 miles S. of Edinburgh. It has a new parish church (1887) and five other modern churches: the Chambers Institution (1859), with library, museum, &c., in the old house of the Yester and Queensberry families; a hydropathic (1881); a public park (1887); tweed-manufactures; and the tower of St Andrew's Church (1196), restored in 1882 by Dr William Chambers (q.v.), who rests beneath its shadow. Mungo Park was a surgeon here. Peebles was made a royal burgh in 1367, and till 1832 returned one member. Pop. (1861) 2045; (1881) 3495; (1891) 4704.

See Dr A. Pennicuik's *Description of Tweeddale* (3d ed. 1875), Dr W. Chambers' *History of Peeblesshire* (1864), Dr John Brown's *Minchmoor* (1864), and *Charters of Peebles* (1873).

Peel, a coast town of the Isle of Man, 11½ miles by rail NW. of Douglas. On Peel Hill (450 feet) is a tower called Corrin's Folly; and on an island sheltering the harbour stand the beautiful ruins of Peel Castle, celebrated by both Scott and Wordsworth. It dates from the 12th century, but was mainly rebuilt by the fourth Earl of Derby in 1593. St German's Cathedral, a cruciform ruin, with a crypt and low central tower, is included in its area. Fishing is Peel's chief industry, but as a watering-place attracts yearly more and more visitors. Pop. (1861) 2848; (1881) 4360; (1891) 3631.

Peel, SIR ROBERT, statesman, was born on 5th February 1788, near Bury in Lancashire. His father, Sir Robert Peel (1750–1830, created a baronet in 1800), was a wealthy cotton-spinner, from whom he inherited a great fortune. He was educated at Harrow, and at Christ Church, Oxford, where he took a double first in 1808, and entered the House of Commons in 1809 as member for Cashel, adopting the strong Tory politics of his father. Perceval was then prime-minister. Peel set quietly about the business-work of the House, feeling his way with that steady prudence and persevering diligence that were the conspicuous features of his character. In 1811 he was appointed Under-secretary for the Colonies; and from 1812 to 1818 he held the office of Secretary for Ireland. In this capacity he displayed a strong anti-Catholic spirit (whence the witty Irish gave him the nickname of 'Orange-Peel'), and was in consequence so fiercely attacked by O'Connell that even the cool and cautious Secretary was stung into sending the agitator a challenge. The police, however, prevented the duel from taking place. From 1818 till 1822 Peel remained out of office, but not out of parliament, where he sat for the university of Oxford. He now began to acquire a reputation as a financier and economist, and in 1819 was appointed chairman of the Bank Committee, and moved the resolutions which led to the resumption of cash-payments. He was still as averse as ever to anything like religious or political reform. No member of the Liverpool-Castlereagh cabinet could have been to appearance more resolute: he even vehemently defended the 'Peterloo Massacre' of 1819. In 1822 he re-entered the ministry as Home Secretary—Canning shortly after becoming Foreign Secretary, on the suicide of Lord Castlereagh. The two worked together pretty well for some time, as Peel devoted himself chiefly to financial matters, and especially to the currency: but 'Roman Catholic emancipation' was a question on which Canning was considerably in advance of his brother-secretary; and when the former was called upon by the king, after the resignation of Lord Liverpool, to form a sort of Whig-Tory ministry, Peel, along with the Duke of Wellington and others, withdrew from office. Yet it is singularly characteristic of this most honest statesman that even when he seceded (1827) his opinions were veering round to the liberal and generous view of the claims of Roman Catholics; and when the death of Canning, shortly after, led to the formation of the Wellington-Peel government, its great measure—actually introduced by 'Orange-Peel' himself—was the ever-memorable one for the 'relief' of the Roman Catholics (1829). As Home Secretary he also signalised himself by a reorganisation of the London police force (since popularly called 'Peelers' and 'Bobbies'), and by the introduction of several other important measures.

Meanwhile, the university of Oxford had rejected its apostate representative, and chosen in his stead Sir Harry Inglis. And now came on the great question of parliamentary reform, which Peel firmly but temperately opposed. In 1830 the Wellington-Peel ministry fell, and was succeeded by a Whig ministry under Earl Grey, which, in 1832, carried the Reform Bill. Peel (now, by the

death of his father, Sir Robert Peel), when he saw that reform was inevitable, accepted defeat and its results with great equanimity. He shrank from anything like factious opposition to the measure, and contented himself with presenting as forcibly as he could the political *per-contra*. After it was passed he became the leader of the 'Conservative' opposition; and, as we have said, accepting reform itself as a *fait accompli* and irreversible, he only sought by a keen and vigilant criticism of Whig measures to retard the too rapid strides of liberalism. In 1833, when the first reformed parliament assembled, Peel took his seat as member for Tamworth, which he represented till the close of his life. On the retirement of the Melbourne ministry in November 1834 he accepted the office of prime-minister, but could not succeed in giving stability to his administration; he was compelled again to give place to Viscount Melbourne in April 1835, and resumed his place as leader of the opposition. Peel's conduct in opposition was always eminently patriotic. The Whigs, who were being pressed on the one side by the new Radical party and the Anti-corn-law League, and on the other by O'Connell and the Irish repealers, gradually lost ground, and, being all but defeated in 1841 on a motion of want of confidence, dissolved parliament. The general election that ensued was virtually a contest between Free Trade and Protection. Protection won; and, when the new parliament met, a vote of no confidence was carried by a majority of ninety-one.

The Conservative party, headed by Peel, now came into office. The great feature of the new government was the attitude it adopted on the corn-law question. The Whigs, while in office, and even after their expulsion, were bent upon a fixed but moderate duty on foreign corn; the Anti-corn-law League would hear of nothing short of an entire repeal, while Sir Robert was in favour of a modification of the sliding-scale of duty which had existed since 1828. He introduced and carried (1842), in spite of strong opposition, a measure based upon this principle. The deficit in the revenue, which had become quite alarming under the Melbourne administration, next engaged his attention, and led him to bring in a bill (1842) for the imposition of an 'income-tax' of 7d. in the pound, to be levied for three years. To alleviate the new burden Peel commenced a revision of the general tariff, and either abolished or lowered the duties on several very important articles of commerce, such as drugs, dye-woods, cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lard. He also showed himself resolute in the repression of the malcontents of Ireland. O'Connell (q.v.) was tried for conspiracy, and, though the judgment against him was set aside on appeal to the House of Lords, the influence of the 'agitator' was broken. The first half of 1845 was marked by the allowance to Maynooth being increased and changed into a permanent endowment instead of an annual grant, and by the foundation of the Irish unsectarian colleges, and other important measures. But the potato-rot in Ireland during the autumn, followed by a frightful famine, rendered 'cheap corn' a necessity, if millions were not to starve. Cobden and the League redoubled their exertions. Lord John Russell announced the views of the Whig party on the crisis, and Peel again yielded. He told his ministerial colleagues that the corn laws were doomed, and that their repeal was inevitable. Some of them refusing to go along with him, he resigned, but after a few days was recalled, and resumed office. Lord Stanley (afterwards Earl of Derby) seceded, and, with Lord George Bentinck, Disraeli (whose savage attacks goaded Peel into sending him a challenge), and others, formed a 'no-surrender' Tory party; but the Duke of Wellington, Graham, Aberdeen, Gladstone, and other eminent Conservatives stood by him, and the measure for the repeal was carried. He was, however, immediately afterwards defeated on an Irish Protection of Life Bill. Not so much upon this account as because he felt that the course which he had pursued had produced a dissolution of the old ties of party, and that he could not expect for some time to find himself at the head of a strong government, Peel retired from office in June 1846, giving place to a Whig administration under Lord John Russell, to which he gave an independent but general support as the leader of a middle party rather Whig than Tory. In the critical times of 1847–48 he was one of the most important props of the government, whose free-trade principles he had now completely accepted. His ecclesiastical policy had also undergone a remarkable change, and he now frankly supported the Whigs in the efforts to carry an act for the repeal of the Jewish disabilities. He was himself regarded by the working and middle classes generally with much grateful respect. He had a keen English interest in sport, and a cultivated taste in matters literary and artistic. An accident put an end to his career. On the 28th of June 1850 he had delivered a great speech against Lord Palmerston in the Don Pacifico matter; but on the following day he was thrown from his horse near Hyde Park Corner, and was so much injured that he died on the night of the 2d of July. He was buried in the church of Drayton Bassett, his Staffordshire home. Peel left five sons, the eldest of whom, SIR ROBERT, and the second, SIR FREDERICK, held office as ministers; whilst ARTHUR WELLESLEY, the youngest (born 1829), was Speaker of the House of Commons from 1884 to 1895, when he was created Viscount Peel.

See *Sir Robert Peel from his Private Papers*, edited by C. S. Parker (3 vols. 1891–99), his *Memoirs* (2 vols. 1857), his *Speeches* (5 vols. 1835 and 1853); monographs on Peel by Guizot (1851), Laurence Peel, Lord Dalling, Barnett Smith, F. C. Montague (1888), Justin M'Carthy (1891), J. R. Thursfield (1891), Lord Rosebery (1899); Shaw Lefevre, *Peel and O'Connell* (1887); Greville's *Memoirs*; Beaconsfield's *Bentinck*; Morley's *Cobden*; Froude's *Beaconsfield* (1890); Croker's *Memoirs* (1884); also CORN LAWS, CATHOLIC EMANCIPATION.

Peel, or PEEL-TOWER, the name given to fortified towers or small castles of the type common on the Scottish border. Originally 'peel' denoted the earthen works, surmounted by palisades, which surrounded and defended the courtyard and tower; but later on the name was applied to the tower itself. See BORDERS, CASTLE; and a monograph by G. Neilson (1896).

Peele, GEORGE, an Elizabethan dramatist, was son of James Peele, Clerk of Christ's Hospital, and was born most probably about 1558. He had his education there, and went up to Oxford in 1571. Next year his name is found on the list of members of Broadgates Hall, now Pembroke College, and from December 1574 to 1579 he was a student of Christ Church. He took his bachelor's degree in 1577, his master's in 1579. He seems to have had a reputation at the university as a poet and arranger of dramatic pageants, but by 1581 he had removed to London, where for seventeen years he lived a roystering Bohemian life as actor, poet, and playwright, dying a discreditable death in 1598. 'As Anacreon died by the pot, so George Peele by the pox,' writes Meres. We know that he married in 1583, and was one of those warned to repentance by the miserable Greene in his *Groats-worth of Wit bought with a Million of Repentance* (1592). Little confidence need be put in *The Merry Jests of George Peele* (1607), which are

mostly ancient and borrowed witticisms, representing Peele as a shifty and disreputable trickster and vagabond haunter of taverns. His best work, *The Arraignment of Paris*, a dramatic pastoral containing some exquisite verse and ingenious flatteries of Elizabeth, was published anonymously in 1584. Another pastoral play, *The Hunting of Cupid* (1591), is lost. In 1585 he was employed to write the Lord Mayor Dixi's Pageant, and in 1591 he prepared another for the mayoralty of Sir William Webbe. His fine and spirited *Farewell* to Sir John Norris in his expedition to Portugal in 1589 (eked out by *A Tale of Troy*); his *Eclogue Gratulatory* (1589) to the Earl of Essex on his return; his *Polyhymnia* (1590), on the retirement of Sir Henry Lee from the office of queen's champion (closing with the exquisite song 'His golden locks time hath to silver turn'd,' quoted in *The Newcomes*); his *Speeches* for the reception of Queen Elizabeth on her visit (1591) to Burghley at Theobalds; and his *Honour of the Garter*, written on the occasion of the investiture of the Earls of Northumberland and Worcester (1593), are other examples of the occasional poems that flowed from his fluent pen, and helped him to make a shifty living.

The historical play of *Edward I.* (1593) has descended in a very corrupt text, and is grievously marred by its baseless slanders against the stainless Queen Eleanor, due to the anti-Spanish prejudice of the time. His bombastic and ranting play, *The Battle of Alcazar*, was published anonymously in 1594, and was followed by another now lost, which in the *Merry Jests* is named *The Turkish Mahomet and Hiren the Fair Greek*. It is doubtless this play that is alluded to in Pistol's 'Have we not Hiren here?' His charming play, *The Old Wives' Tale* (1595), which most probably gave Milton the subject for his *Comus*, is well defended by Mr Bullen from the contemptuous criticisms of Symonds and Saintsbury. The latter, however, finds much higher poetic merit in *David and Bethsabe* (1599) than either Mr Bullen or Charles Lamb. The last work assigned to Peele is *Sir Clyomon and Sir Clamydes* (1599), but its authorship is more than doubtful.

Peele's works were first collected by Dyce (2 vols. 1828; 2d ed. 1829; a supplementary 3d volume in 1839). A carefully revised re-issue was published, together with Greene, in 1861. The best edition is that by A. H. Bullen (2 vols. 1888). See Ward's *English Dramatic Literature* (1875), and J. A. Symonds' *Shakspere's Predecessors* (1884).

Peep o' Day Boys, an Ulster Protestant association (1780–93).

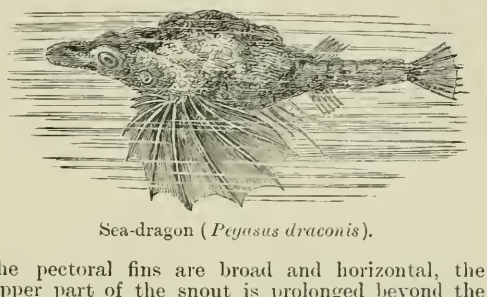
Peepul, or PIPAL (*Ficus religiosa*), also known as the SACRED FIG of India, and in Ceylon called the BO-TREE, a species of Fig (q.v.), somewhat resembling the Banyan, but the branches not rooting like those of that tree, and the leaves heart-shaped with long attenuated points. The tree is held sacred by the Hindus, because Vishnu is said to have been born under it. It is generally planted near temples, and religious devotees spend their lives under its shade. It is also held sacred by the Buddhists of Ceylon (see BO-TREE). It attains a great size and age. The peepul is often planted near houses, and by the sides of walks, for the sake of its grateful shade. The juice contains a kind of caoutchouc, and is used by women as bandoline. Lac-insects feed upon this tree, and much lac is obtained from it. The fruit is not much larger than a grape, and although eatable is not valued.

Peerage. See NOBILITY, PARLIAMENT.

Peewit. See LAPWING.

Pegasus, in Greek Mythology, a winged horse which arose with Chrysaor from the blood of the Gorgon Medusa, when she was slain by Perseus. He is said to have received his name because he first made his appearance beside the springs (*pēgai*) of Oceanus. He afterwards ascended to heaven to carry the thunder and lightning of Zeus. Some later authors make him the horse of Eos. Bellerophon had in vain sought to catch Pegasus for his combat with the Chimæra, but at length was advised by the seer Polyidus of Corinth to sleep in the temple of Minerva. The goddess appeared to him in his sleep, and gave him a golden bridle with which he caught him, and by his aid overcame the Chimæra. Modern writers ignorant of mythology make Pegasus the horse of the Muses, with whom, however, he had nothing to do beyond having by a kick of his hoof made spring up the inspiring fountain of Hippocrene.

Pegasus, a genus of small fishes of uncertain affinities. The body is covered with bony plates,



Sea-dragon (*Pegasus draconis*).

the pectoral fins are broad and horizontal, the upper part of the snout is prolonged beyond the mouth, which is toothless. Four species are known: *P. draconis*, from the Indian Ocean; *P. volans*, often put inside Chinese insect-boxes; *P. natans* and *P. lancifer*, from Chinese and Australian coasts.

Pegmatite, a variety of Granite (q.v.).

Pegu, a town, division, and river of Lower Burma. The *town* stands on the river Pegu, 46 miles NE. of Rangoon. The old city was founded in 573 and was made the capital of a powerful independent kingdom. European travellers in the 16th century speak of its great size and magnificence. It was destroyed in the middle of the 18th century by Alompra; but was rebuilt. A celebrated pagoda still stands within part of the old walls. The place was handed over to the British by the inhabitants both in the first and the second Burmese war. Pop. 10,762.—The *division* has an area of 9160 sq. m. and a pop. (1891) of 1,456,489.—The *river* rises in the Pegu Yoma Mountains, and flows generally south for 180 miles, joining the Rangoon or Hlaing River.

Pehlevi, an ancient West-Iranian (Median and Persian) idiom, in use chiefly during the period of the Sassanides (235–640 A.D.). See PERSIA, ZEND.

Pei-ho, a river of China, rises near the borders of Mongolia, flows north-east and south-east, past Peking and Tien-tsin, and falls into the Gulf of Pe-chi-li after a course of more than 350 miles. The mouth of the river is defended by the powerful forts of Taku (q.v.). See CHINA.

Peine Forte et Dure, the 'strong and sore torture,' a species of torture formerly applied by the law of England to those who, on being arraigned for felony, refused to plead, and stood mute, or who were guilty of equivalent contumacy. In the reign of Henry IV. it had become the practice to load the offender with iron weights, and thus press him to death; and till nearly the middle of the 18th century pressing to death in this horrible manner was the regular and lawful mode of punishing persons who stood mute on their arraignment for felony. Latterly a practice

prevailed, which had no sanction from the law, of first trying the effect of tying the thumbs tightly together with whipcord, that the pain might induce the offender to plead. Among instances of the infliction of the *peine forte et dure* are the following: Juliana Quick, in 1442, charged with high-treason in speaking contemptuously of Henry VI.; Margaret Clitheron, 'the martyr of York,' in 1586, for her constancy to the Catholic faith; Walter Calverly of Calverly, in Yorkshire, arraigned at the York assizes in 1605, for murdering his two children and stabbing his wife; and Major Strangways, in Newgate in 1657, for refusing to plead when charged with the murder of his brother-in-law. In 1720 a person of the name of Phillips was pressed in Newgate for a considerable time, till he was released on his submission; and the same is recorded in the following year of one Nathaniel Hawes, who lay under a weight of 250 lb. for seven minutes. As late as 1741 a person is said to have been pressed to death at the Cambridge assizes, the tying of his thumbs having been first tried without effect. A statute of 1772 virtually abolished the *peine forte et dure*, by enacting that any person who shall stand mute when arraigned for felony or piracy shall be convicted, and have the same judgment and execution awarded against him as if he had been convicted by verdict or confession. A later statute (1828) made standing mute equal to a plea of 'not guilty.'

Peipus, Lake, in the north-west of Russia, lies between the government of St Petersburg and the province of Livonia. On the south it is connected with Lake Pskoff by a long, narrow channel, the length of both lakes being 87 miles, the greatest breadth about 30, the area 1356 sq. m., and the depth from 14 to 49 feet. Their waters, which abound in fish, are carried to the Gulf of Finland by the Narova. The shores are marshy and flat.

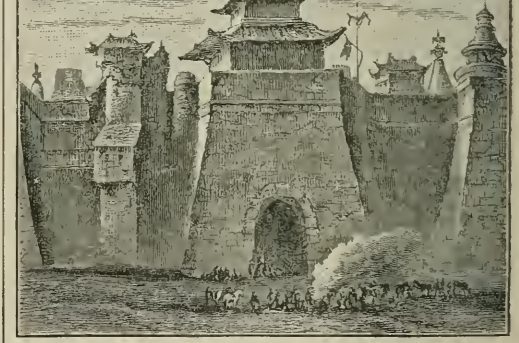
Peirce, Benjamin, mathematician, was born at Salem, Massachusetts, 4th April 1809, and studied at Harvard, where in 1833 he became professor. In 1849 he became consulting astronomer to the American Nautical Almanac; and from 1867 to 1874 he was superintendent of the Coast Survey. In 1836–46 he issued an admirable series of mathematical text-books, and he contributed to various mathematical journals. His paper on the discovery of Neptune (1848) attracted universal attention; and his papers on the constitution of Saturn's rings (1851–55) were equally remarkable. His great *Treatise on Analytic Mechanics* appeared in 1857; and he left his mark on various departments of mathematical and astronomical investigation. He died at Cambridge, 6th October 1880.

Peishwa. See Mahrattas.

Pekan, or Wood-Shock (*Martes pennanti*), an American species of Marten (q.v.), the largest of all the species, was formerly common in North America from Alaska and the Slave Lake into the central United States, but is now extinct in settled districts. There seems to be nothing in its habits to justify its common name of Fisher or Fisher Marten; by hunters it is called Black Fox.

Pekin, capital of Tazewell county, Illinois, on the Illinois River, 10 miles by rail S. of Peoria. It has several foundries, flour-mills, distilleries, and manufactories of organs, ploughs, wagons, &c. Pop. 5993.

Peking, or, as now often pronounced, Pei-Ching (i.e. 'Northern Capital'), the capital of the Chinese empire, is in 39° 54′ 36″ N. lat. and 116° 27′ E. long. It is situated in a sandy plain, and is surrounded by many-gated walls, with suburbs smaller than most other large cities in the country. The visitor coming to it from Tien-tsin is not prepared for his approach to it by villas and mansions with their parks and gardens, such as greet him in drawing near to the capitals of the West. At a turn in the road the city bursts at once on his view, standing up grand and grim, complete in itself with its lofty walls, and the loftier towers upon them. The city consists, in fact, of two cities—the Inner and the Outer—known also as the Manchu or Tartar and the Chinese, the Northern and the Southern. They are separated by a high wall common to them both, but properly belonging to the former, and giving it the appearance of nearly a square, on which the other partly rests in the form of a rectangle, its southern and northern walls longer than those of the square, but the other two shorter. The walls of the Manchu city average 50 feet in height, and are fully 60 feet wide at the bottom and 40 at the top; the dimensions of those of the Chinese city are less—30 feet in height and 25 and 15 in width. Those of the former measure 14¼ miles in circuit, including its part of the cross-wall, and those of the Chinese city 10. Not counting the cross-wall, the whole circuit measures about 21 miles, including altogether an area of nearly 26 sq. m. In all Peking has sixteen gates. Over each is raised a tower about 100 feet high, and of very imposing appearance. All the gates of the Manchu city are



Gateway at Peking.

guarded by semicircular enceintes, enclosing a yellow-tiled temple to Kwan Ti, a hero of our 2d century, now honoured as the 'god of war.'

When a stranger has entered by a gate of the Northern City, and rides or drives along the cross-wall to its central gate, he is greatly impressed by the magnificence of the walls and towers, and readily believes Peking is the grandest city in the world. Such was the feeling of the writer when he entered it in 1873; after he had passed through the gate, there stretched before him, as far as his eye could reach, a street about 200 feet across, lined with what seemed to be brilliant shops on each side, with wide spaces for foot-passengers, and between them a carriage-way, raised about two feet, on which a constant stream of vehicles, with horses, mules, camels, and donkeys, was hurrying. But by-and-by this impression of the magnificence of the city was displaced by another of the dilapidation and decay, squalor and filth, which everywhere obtruded themselves.

Peking is one of the most ancient cities of the world. On the same site stood the metropolis of the feudal state of Yen, whose history is traceable back to the 12th century B.C. In our 10th and 12th centuries two Tartar tribes which attempted

to impose their sovereignty on the empire made the old metropolis of Yen their capital. The second of them, which had absorbed the other, fell before the invading Mongols in the 13th century, and Kublai, a grandson of Genghis Khan, enters the chronological line as sovereign of all China in 1280. He made Peking his capital, and there he was found by Marco Polo, who styles the city *Khan-baligh*, 'the city of the Khan,' a name frequently corrupted in old narratives into *Cambaluc* and *Cambalu*. Within a century the Mongols were driven out of the empire by the Chinese Ming dynasty, the founder of which at first fixed his capital at what we call Nanking (q.v.). The third Ming emperor, called from the name of his reign Yung-lo, on his accession in 1403 made preparations to transfer the seat of government back to the Kublai site. This movement was carried out in 1421. The south wall of the Inner City was carried half a mile beyond that of Kublai; and a later emperor built in 1552 the wall of the Outer City.

However, the Manchus, when they became masters of the empire in 1643, found this great city ready for them. They had only to maintain it in good condition, and for a time they did so; but for more than a century it has been allowed to go very much to decay. As Dr Williams observes, 'Peking stands to-day, like the capitals of the ancient Roman and Byzantine empires, upon the debris of centuries of buildings.' A new era in its history commenced in October 1860, when it was surrendered to the English and French allies, leading to the establishment of the various foreign legations in the Inner City, and to the reception of the ministers, though not in the Forbidden City, in June 1873 by the emperor in person.

The Manchu or Inner City is divided into three portions, the largest of which by far may be called the General City. But at the heart of it are two enclosures, into the innermost of which entrance is entirely forbidden to foreigners, and also to the Manchus and Chinese themselves, excepting such as have some official connection with the court. It is called the Purple Forbidden City, is very nearly 2¼ miles in circuit, and constitutes in fact the imperial residence. In it are the palaces of the emperor, his empress, and other members of the imperial family. But there are also other palaces and buildings not a few—for instance, several reception halls (*tien*). The one which a visitor, entering by the 'Meridian Gate,' would first approach is the *T'âi Ho*, or 'Hall of Grand Harmony,' built of marble on a terrace 20 feet high, and rising itself other 110 feet. Its principal apartment is about 200 feet long and 90 wide, and is furnished with a throne for the emperor, who holds his levées here on New-year's Day, his birthday, and other great occasions. Here, too, is the 'Palace of Heavenly Purity,' where the emperor meets his cabinet at dawn for the transaction of business. In this enclosure also is one of the four great 'arsenals,' or collections of the works arranged in the Chien-lung period for the Great Library; and here was the Wû-ying printing-office, burned down in 1869.

Surrounding the Forbidden City is the 'Imperial' or 'August,' an oblong rectangle, about 6 miles in circuit, and encompassed by a wall 20 feet in height. In the space between the wall on the south and that of the Forbidden City, on the right or east of the avenue from the front gate of the cross-wall, stands the great temple in which the emperor and the members of the imperial clan worship their ancestors. Opposite to it, on the west or the left of the avenue, is the altar to 'the Spirits of the Land and Grain.' In the corresponding space on the north, between the two enclosures, there is an artificial mound 150 feet high, crowned at five different points with as many Buddhist temples, and well wooded all over. It is called the *King Shan*, loosely translated 'Prospect Hill,' and affords the finest view of the entire city. It is separated from the Forbidden City by a moat, which is crossed by more than one marble bridge. Among the people the common name for it is 'Coal Hill,' their belief being that it was formed by stores of coal, deposited there by way of provision against a siege. The western portion of 'the August City' goes by the name of the Western Park. A principal attraction in it is an artificial lake more than a mile long, though not nearly so wide, fed by a stream brought from the hills to the west of the city, which used also to supply the moat all round the walls. The lake is crossed by a marble bridge of nine arches, and in the proper season its surface is beautiful with the large, brilliant flowers of the lotus. At the south end of the park are the summer-house, the rockwork, the gardens, and the hall for the examination of military candidates, and at the opposite end the copper statue of *Maitreya* (the coming Buddha, 60 feet high, with one hundred arms), the temple of 'Great Happiness,' the altar and temple dedicated to Yüan Fei (2500 B.C.), the discoverer of the uses of the silkworm, with a plantation of mulberry-trees and a cocoon-house near it. The empress annually comes here with her ladies to offer sacrifice to this Yüan Fei, to feed the silkworms, and to unwind some of the cocoons, as an example to the women of the empire.

We now come to the General City. On either side of the avenue leading from the central gate of the cross-wall to the August City are the principal offices of the government—the six boards and the Censorate. In the same neighbourhood are the observatory, the Provincial Hall for literary examinations, the Colonial Office, and the *Han Lin Yüan*, which we call the 'National Academy,' and to belong to which is the highest literary distinction in China. Its members are many and of various grades. All the literary work of the government may be said to pass through their hands.

In the north-eastern corner of the city is the Russian mission, and west from it the *Yung Ho Kung*, or 'Palace of Everlasting Harmony,' a grand lamasery, where more than a thousand Mongol and Tibetan monks dwell, and are provided for, while they study their religion under the rule of a *Gegen*, or 'living Buddha.' At the north end is a lofty building containing a wooden image of Maitreya, 70 feet high. A little farther to the west stands, amidst many cypresses, the temple of Confucius, under the ancient name of *Kwo-tsze Chien*. In the lofty hall are the spirit-tablets of the sage and his most celebrated disciples and followers—nothing else. Close by these rises from a circlet of water the *Pi Yung Kung*, commonly called 'The Hall of the Classics,' from the most remarkable thing about it—182 pillared slabs of granite, reared up in two corridors, and having the text of all the classical books engraved on them, in front and behind, in large characters.

In the western side of the city are the headquarters of the *T'i-tuh*, or 'general-in-chief,' who has the control of the police and garrison of the city, and very much directs its civil administration. Here also are the Drum and Bell Towers, both conspicuous objects. Five great bells were cast in the Yung-lo period, early in the 15th century. One of them is here, another about 2 miles in a north-west direction from the city, in 'The Great Bell Temple.' It is indeed a monster, 14 feet high, 34 feet in circumference at the rim, and 9 inches thick, and is said to weigh 120,000

lb. (see BELL). It is covered, inside and out, with myriads of Chinese characters, from the *Fah Hwa* and *Ling Yen*, two Buddhist sutras.

Going towards the south wall, we note two great structures on our way. One is the *Tî Wang Miâo*, or 'Temple of Emperors and Kings,' where the reigning emperor goes to worship the spirits of nearly two hundred sovereigns, who have ruled from Fû-hsî (at least 3000 years B.C.) down to the present dynasty, and with them are associated the spirits of the ablest and best of their ministers. The other structure is the great Tutelary (wall and moat) Temple of the capital, grimy, and full of fortune-tellers and other quacks, like the corresponding temples throughout the country. All the foreign legations and all the Christian missions are situated within the Inner City; conspicuous among the latter is the new Roman Catholic cathedral, a magnificent structure, completed in 1888.

The Chinese or Outer City is very sparsely populated. Much of the ground is under cultivation, large tracts are wooded, green fields show themselves, and other open spaces are occupied with artificial lakes and tanks. Where it is built over, the streets are for the most part narrow, and the people are busy and bustling. There are club-houses not a few, various temples, and charitable institutions for the poor, the aged, and for children, the latter in the shape of foundling hospitals, as in the Inner City. The *T'ien Tan*, or 'Altar to Heaven,' with its adjunct the *Ch'i Kû Tan*, or 'Altar of Prayer for Grain,' and the 'Altar of Agriculture,' dedicated to the ancient sovereign, Shân Nung, to whom the first teaching of husbandry (about 3000 B.C.) is ascribed, are both near the southern wall, and are reached by a 'great street,' or avenue. The first two altars are enclosed by more than three miles of wall, the space within planted with forest trees. Within a second wall is a grove of fine cypresses encompassing the buildings. The 'Altar to Heaven' stands on a splendid triple circular terrace of white marble, with steps leading from one terrace to the next, each being surrounded by a balustrade of the same marble, richly carved. On the upper terrace, which is 30 feet in diameter and about 20 feet above the ground, the emperor appears to greet the dawning sun on the day of the winter solstice, attended by his grandees and ministers. He has passed the night in the 'Fasting Palace,' which is not far off, in religious vigil. His own place at the altar, where he stands and kneels, is a large circular slab, unflawed and unstained. In front of him is a pavilion containing the tablet for the spirit of *Shang-Ti*, or God, and on either side, in smaller pavilions, are the tablets of his own ancestral line. The religious service that is then celebrated has been performed from time immemorial. The 'Altar of Prayer for Grain,' a similar structure, but of less dimensions, was burned down on 18th September 1889; on its upper terrace there was a triple-roofed circular building, the imposing appearance of which with the splendour of its blue tiles made it be regarded as more important than the other altar and be commonly, though erroneously, styled by foreign visitors 'The Temple of Heaven.' To this altar the emperor comes in the early spring to pray for a blessing on the labours of the year. Here also he repairs in seasons of drought to pray for rain, but without any pomp of state. He must plod his way on foot to the 'fasting place,' and there brood over his own sins and errors of government before he dares to ascend the altar. A short distance to the east stands 'the Altar of Agriculture,' in an enclosure about two miles in circumference. This contains four different altars—to the Spirits of the Sky, of the Earth, of the planet Jupiter, and of the old Shân Nung. But all these spirits are honoured and sacrificed to, not as independent powers, but as 'servants of *Shang-Ti*,' doing his will for the good of men. The planet has an altar because of the connection which the period of its revolution has with the sexagenary cycle. The chief attraction of the spot is the ceremony of ploughing which takes place there in the spring. The emperor comes to it attended by certain of his great officials, and turns up a few furrows in a portion set apart for him, as an example of agricultural industry to all his people. Some of the provincial magistrates have portions assigned to them for the same purpose. The ceremony is copied and grotesquely performed by the authorities throughout the country. The principal streets of the Chinese city are more than 100 feet wide, but the side streets are mere lanes. The streets are not usually paved, and according to the state of the weather are deep in mud or in dust. In the smaller streets the houses are miserable shanties; in the main streets both private houses and shops are one-story brick edifices, the shops being gay with paint and gilding. The shops are open in front, the goods being often piled up outside; and many trades are carried on in the streets or in tents and movable shops.

Amongst places of interest to visitors are also the various government offices, the old offices for entertaining foreign embassies, and the legations where since 1861 the foreign ministers accredited to China actually reside. There are three Catholic cemeteries (Portuguese, French, and native) and a Russian one; and there are mission buildings, Russian and other, and hospitals. Free schools are not infrequent in the city. The climate of Peking is severe, the temperature in winter being from 25° to 10° F., and in summer the heat is great, the thermometer rising to 105°, though the usual summer temperature is 75° to 90°.

As to the population of Peking, Du Halde estimated it at about three millions two hundred years ago. The writer's impression is that in the last quarter of the 19th century it was under a million. No doubt it has fluctuated considerably with the fortunes of the dynasty. Dr Williams, after living in the city for years and being chargé d'affaires of the American legation, says that the residents most likely to form a correct judgment put down the entire population at a million or somewhat less. 'No census returns,' he adds, 'are available to prove this figure, nor can it be stated what is the proportion of Manchus, Mongols, and Chinese, except that the last outnumber both the others.'

During the crisis in the history of the empire to which the Japanese war of 1894–95 led, Peking has witnessed various *coups d'état*, and was a centre of intrigue on the part of the European powers, vast railway schemes being eagerly promoted in the various competing interests. The railway from Peking to Tien-tsin (73 miles) was opened in 1897; and the lines for which, in the scramble of 1898–99, concessions were granted connect Peking with Hankow and Canton, and with the Manchurian and Siberian systems. The Chinese telegraphs were connected with Siberian lines, and so with Europe, in 1892. The events of 1900 have been recorded at CHINA, Vol. III. p. 194—the 'Boxer' troubles, the eight weeks' siege of the legations, the expedition of the European and other allies, the withdrawal of the court to Singanfoo, the relief of the legations by the entry of the allies on 14th August, the occupation of the 'Forbidden City,' and the tedious and protracted peace negotiations.

Though great Asian trade routes to Kulja and Semiretchinsk start from Peking, the commerce of the city itself is inconsiderable; provisions are very dear, and many of the people are very poor and

miserable. The manufactures are unimportant. The government of the city is distinct from that of the department, and is administered by a superintendent (a high imperial functionary), a mayor, and officers in the several quarters. The police have often trouble in keeping order; some 10,000 soldiers or militia are quartered in the town. The daily *Peking Gazette*, a pamphlet of sixty to seventy pages, is the imperial official journal. Since 1868 there has been an imperial university with American and European professors.

As to the reproach of infanticide which has been current against the population, Dr Edkins says: '*Infanticide is almost unknown in Peking.* The dead-cart which traverses the streets at early morning receives the bodies of poor children dying by ordinary causes and whose parents are not able to bury them. The mothers would rather, if not willing to keep their infants, carry them to the foundling hospitals, which are established in the Inner and Outer Cities, than take their lives. At present the people are not aware of the existence of infanticide, nor is this atrocious custom known in the surrounding country; indeed, it exists only in some provinces, four or five in number. The dead-cart is in connection with the foundling hospitals.'

See Rennie's *Peking and the Pekingese* (1865); Williamson's *Journeys in North China*, especially chapter xvi., which was contributed by Dr Edkins (1870); Martin's *Chinese: their Education, Philosophy, and Letters* (1881); Williams's *The Middle Kingdom* (revised ed. 1883); and other works cited under CHINA.

Pelagius, a celebrated heresiarch of the 5th century. He was probably born about the middle of the 4th century, in Britain, or, according to some, in Brittany, his name being supposed to be a Greek rendering (*Pelagios*) of the Celtic appellative *Morgan* ('sea-born'). He was a monk, but he never entered into holy orders. He settled in Rome about 400, where he seems to have been scandalised by the low tone and morals then obtaining. His views seem to have been early developed; and during his stay in Rome he seems to have given them full expression—especially in his commentaries on the Pauline Epistles, which were published at this time. It has been remarked that his doctrinal tendencies have something in common with those of the Eastern Church, and may therefore be taken as showing that Eastern influences were still alive in the British churches. But more probably his theology was the outcome of his own devout and earnest, but narrow and anti-speculative mind. Jerome and Orosius tell tales to his discredit; but these are refuted by the respect with which Augustine always speaks of his character and conduct. The controversy about Pelagianism was not started by Pelagius, but by a devoted disciple of his. In Rome he had attached to his views a follower of great energy named Cœlestius, probably an Irish Scot, originally a lawyer, who was practising in Rome when Pelagius came thither. He became a monk, and accompanied Pelagius wherever he went. In 410, after the sack of the city by the Goths, the two withdrew to Africa. After some time Pelagius made a pilgrimage to Jerusalem, where he met St Jerome. Cœlestius having remained at Carthage, and sought to be admitted to ordination, his doctrines became the subject of discussion, and in a synod several opinions ascribed to him were condemned—proceedings which introduced St Augustine into the controversy. Meanwhile Pelagius remained at Jerusalem, and news of the proceedings at Carthage having been carried to Palestine, in 415 he was accused of heresy before the synod of Jerusalem. As adopted by Cœlestius, his doctrines seem to have been a reaction against Gnosticism, Manichæism, and Fatalism, in the interest as he conceived of a higher morality than he found in Rome. The Pelagian heresy was held to deny original sin; Adam's sin injured himself only; his posterity are born as innocent as he was before the fall. Adam would have died even if he had not sinned. Children are baptised that they may be united to Christ, not that they may be purged from original sin. It is possible to live without sin. Grace as understood by the Catholic Church was not required; free-will and the teaching of the law may suffice; Pelagius did not grant that the will must be moved by God before a man can take one step onwards towards life eternal. The essence of the doctrine is a view of the freedom of the will that may be called liberty of indifferences; the will is equally free to choose to do good and to do evil. This freedom is found also in heathens; and thus natural ability heightens human responsibility, while it seems to diminish the need of divine grace.

The impeachment failed, and in a synod subsequently held at Diospolis in the same year Pelagius evaded condemnation by accepting the decrees of the synod of Carthage. But a new synod of Carthage in 416 condemned Pelagius and Cœlestius, and wrote to Pope Innocent I. requesting his approval of the sentence, with which request Innocent complied. Zosimus, the successor of Innocent, wavered; but a council of 214 bishops was held in Carthage, in which the doctrines of Pelagius were formally condemned in nine canons; and on receipt of these Zosimus reopened the cause, cited and condemned Cœlestius and Pelagius, and published a decree adopting the canons of the African Council, and requiring that all bishops should subscribe them, under pain of deposition. Nineteen Italian bishops refused to accept these canons and were deposed. Their leader was Julian, Bishop of Eclanum, near Beneventum. Pelagius himself was banished from Rome in 418 by the Emperor Honorius, and he and Cœlestius were again condemned by the Council of Ephesus in 431. The date and place of the death of Pelagius are not known. The most important of the writings on the Pelagian side have been lost. Julian is chiefly known through the replies of Augustine, whose anti-Pelagian treatises are edited by the Rev. Dr W. Bright (1880). Pelagius's *Fourteen Books of a Commentary on St Paul's Epistles*, his *Epistle to Demetrius*, and his *Memorial to Pope Innocent*, included by collectors in the works of St Jerome, are much mutilated, but yet almost certainly genuine. All his other works have been lost, except some fragments.

SEMI-PELAGIANISM was a modification of the doctrine of the Pelagians as to the powers of the human will, and as to the effects to be attributed to the action of the supernatural grace of God, and of the divine decree for the predestination of the elect. The Pelagians, discarding altogether the doctrine of the fall of Adam, and the idea that the powers of the human will had been weakened through original sin, taught that man, without any supernatural gift from God, is able, by his own natural powers, to fulfil the entire law, and to do every act which is necessary for the attainment of eternal life. The condemnation of this doctrine by the several councils held in the early part of the 5th century is capable of various constructions, and has been urged by some to the extreme of denying altogether the liberty of man, and converting the human will into a merely passive instrument, whether of divine grace upon the one hand, or of sinful concupiscence upon the other. The writings of St Augustine on this controversy have been differently construed by the different Christian communions, and the same diversity of opinion existed in his own day. Among those who, dissenting from the extreme view of Pelagius, at the same time did not go to the full length of

the Augustinian writings in opposition to Pelagius, were some monks of the southern provinces of Gaul, and especially of Marseilles, whence their school was called Massilian, from the Latin name (*Massilia*) of that city. Of these leaders the chief was a priest named Cassian (Joannes Cassianus), who had been a deacon at Constantinople. Of the system which he propounded it may be enough to say that it upheld the sufficiency of man's natural powers only so far as regards the first act of conversion to God and the initial act of man's repentance for sin. Every man naturally possesses the capability of beginning the work of self-conversion; but for all ulterior acts, as well as for the completion of justification, the assistance of God's grace is indispensable. The Semi-Pelagian doctrine is often confounded with that of the Molinistic (see MOLINA) school of Roman Catholic theology; but there is one essential difference. The latter persistently maintain the necessity of grace for all supernatural acts, even for the beginning of conversion, although they are generally represented as agreeing with the Semi-Pelagians as to the mode of explaining the freedom of the human will acting under the influence of divine grace. The chief writers in the controversy were Prosper, Hilary, and Fulgentius; and the question was referred to Celestine, Bishop of Rome in 431. It continued, however, to be agitated in the West for a considerable time. Faustus, Bishop of Reji (Riez in the Basses Alpes), towards the end of the 5th century revived the error, and it was condemned in a council held at Arles in 475, and still later in a synod (the second) held at Arausio (Orange) in 525, and again in the third council of Valence in 530. The words of Augustine were formally accepted; but the tendency which produced Pelagianism and Semi-Pelagianism has often reappeared.

See works on Pelagius by Wiggers (1832; trans. by Emerson, Andover, 1840); Jacobi (1842); Wörter (1866); Klasen (1882); for Semi-Pelagianism, the monograph of Geffken (1826); also the articles AUGUSTINE, JANSENISM, PREDESTINATION, SIN, WILL.

Pelargonium, a genus of plants of the natural order Geraniaceæ, including many of the most favourite greenhouse flowers, to which the old generic name Geranium is often popularly given. The characters which distinguish pelargonium from geranium, as now restricted by botanists, are given in the article GERANIUM. The species are numerous, and mostly natives of the Cape of Good Hope, of certain other parts of South Africa, and a few are natives of the Canary Islands. Some of them are herbaceous and some are stemless; most of them are half-shrubby. Some have tuberous rootstocks. The leaves exhibit great variety in form, division, &c. The flowers always adhere to a certain type in form, but with great variety in size, colour, &c.; they are always in stalked umbels, which arise from the axils of the leaves, or in the stemless kinds from the midst of the leaves. In no genus has the art of the gardener produced more striking results than in this; and the number of beautiful hybrids and varieties is very great, some of them excelling in beauty any of the original species. Some species not possessing much beauty of flower are cultivated for the grateful odour of their leaves, which in some resembles that of roses, in others that of apples, lemons, &c.; whilst that of many species is rather unpleasant. The cultivation of pelargoniums is similar to that of other Geraniaceæ (see GERANIUM). A few of the species endure the open air in the south of England; many are planted out in summer even in Scotland. Water must be liberally supplied to pelargoniums during the time of flowering; but no plants more strongly require a period of rest, and water must then be very sparingly given. The shrubby and sub-shrubby kinds are easily increased by cuttings either of the branches or the roots, stout pieces of the latter being the most fit for the purpose. Sandy soil and very moderate supplies of water are requisite till the cuttings are rooted, when richer soil and a more liberal supply of water are needed. The tuberous-rooted species are increased by cuttings of the roots and by seed.

Pelasgians, a term somewhat variously used for certain inhabitants of ancient Greece. In Homer the Pelasgi seem to have been an unimportant tribe living in Thessaly. Herodotus seems to regard the Pelasgi not as Hellenic, but as barbarians who had occupied Hellas or parts of it ere the Hellenes came thither (see GREECE, Vol. V. p. 386). Modern students have also interpreted the term differently. Some regard the Pelasgians as the pre-Aryan occupants of Greece, others as the Græco-Italians—i.e. the common ancestors of the Greeks and Italians. The truth is that we know little or nothing of the pre-Aryan occupants of Greece, or of the Græco-Italians, or of the builders of Cyclopean works, and that there are no reasons for identifying any of them with the insignificant tribe of Pelasgi. Then 'Cyclopean' (or less frequently 'Pelasgian') is a name applied to certain architectural works in Greece, which probably date from before 1000 B.C., and are wholly unconnected in point of evolution with any style of Greek architecture subsequently developed. The characteristic which distinguishes Cyclopean work from any other form of architecture is that it consists of huge polygonal stones, which may or may not be so arranged as to fit into one another without interstices requiring lesser stones to fill them up, but which are always hewn and are always kept in their places not by means of mortar or any other binding substance, but by their own great weight. On the other hand, work of this kind is not necessarily ancient: other considerations than the nature of the work itself are requisite to date it. Nor is it confined to Greece: similar remains are to be found in Egypt, Asia Minor, Sicily, Sardinia, Spain, &c., as well as in Greece and Italy. The most important ancient Cyclopean works in Greece are the walls of Tiryns, Psophis, and Mycenæ, the Lion Gate and so-called Treasuries (graves) of the latter place, and a (probable) temple on Mount Ocha. These Cyclopean walls (especially at Tiryns) were so thick as to allow galleries to be run lengthwise through them. At Tiryns window-like openings look down from these galleries on to the town. That these galleries served the purposes of fortification in some way is clear, but in what way is not clear. The walls are broken by gates, of which the best known is the celebrated Lion Gate at Mycenæ. In this form of doorway, in order to relieve the pressure on the lintel (which rests horizontally on the perpendicular stone doorposts), a triangular space is left above the lintel, and this space is filled, in the case of the Lion Gate, with a slab, on which are sculptured the figures of two animals (not lions) rampant, one on either side of a pillar. This quasi-heraldic device is undoubtedly of oriental origin, or imitated from some Assyrian model, but proves nothing as to the origin of the architecture or its builders. The same means for relieving the pressure on the lintel is employed in ancient remains in Cornwall. The Treasuries or tombs are underground chambers in the shape of bee-hives, vaulted with overlapping stones, and approached by a narrow passage through the side of the hill in which they are situated. The interior was ornamented with plates of bronze attached to the masonry. The term Cyclopean was applied by the Greeks to this kind of architecture on the strength of the popular

etymology of the term: *cyclopes* = builders of a 'cycle,' or ring-wall. See CYCLOPES.

Pelayo, said to have been the first Christian king of Spain, seems to have made head against the Arabs in Asturias (q.v.) in the 8th century. See SPAIN.

Pelesch, a royal castle of Roumania, built by Doderer of Vienna in 1873–84, in a romantic situation on the south side of the Transylvanian Alps, 70 miles N. of Bucharest.

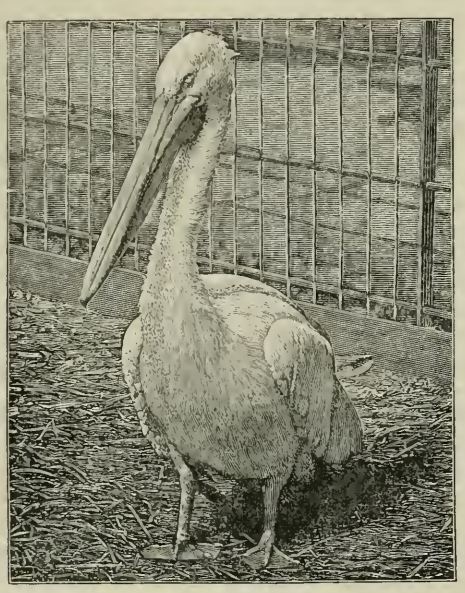
Pelew Islands, also PALAU, a group in the Pacific belonging to Spain, lie south-east of the Philippines, at the western extremity of the Caroline Archipelago, with which they are sometimes classed. There are about twenty-five islands, mountainous, wooded, and surrounded with coral-reefs. Total area, 170 sq. m. The principal is Babelthouap or Babeltop. The soil is rich and fertile, and the climate healthy. Bread-fruit, cocoa-nuts, sugar-cane, palms, areca-nuts, yams, &c. are grown. Turtles, trepang, and fish abound on the coasts. The inhabitants, about 10,000 in number, are of the Malay race. The men go entirely naked and the women nearly so. They are described as being good-natured, and have peculiar social institutions —the women too. The islands were discovered by the Spaniards in 1543, and visited again in 1696. See Semper, *Die Palauinseln* (1873); Knbary, *Die sozialen Einrichtungen der Palauer* (1885); and Marche, *Luçon et Palouan* (Paris, 1887).

Pelham, THE FAMILY OF, takes its name from a castle and lordship in the north-east of Hereford, and was elevated to the peerage in the person of Sir Thomas Pelham, who in 1706 was created Baron Pelham, and married Lady Grace Holles, sister of the Earl of Clare. His successor, THOMAS PELHAM HOLLES, Duke of Newcastle, and minister of the first two Georges, was born in 1693, and educated at Westminster and Clare Hall, Cambridge. In 1711 he succeeded to the vast estates of his maternal uncle the Duke of Newcastle, and next year to the peerage of his father, the first Lord Pelham. George I. rewarded his services by creating him Earl of Clare (1714) and Duke of Newcastle in Northumberland (1715). He was made Lord-lieutenant of Middlesex and Nottingham, and a Knight of the Garter in 1718, and in the same year he married Lady Henrietta Godolphin, granddaughter of the great Marlborough. In 1724 he succeeded Carteret as Secretary of State, and held the office continuously under Walpole and his successors for thirty years, although a man of no particular ability except in parliamentary tactics. In 1754 he succeeded his brother, Henry Pelham, as premier, but retired in November 1756 to give place to the Duke of Devonshire, himself being rewarded with the title of Duke of Newcastle-under-Lyme, with special remainder to the Earl of Lincoln, his niece's husband. In July 1757 he was again premier, and compelled to take the first William Pitt into his ministry and to give him the lead in the House of Commons, and the supreme direction of the war and of foreign affairs. A succession of brilliant victories followed—Newcastle being only nominal head of the administration—and the great commoner had almost brought the war to a successful termination, when the accession of George III. led to the resignation of Pitt, and the replacement of Newcastle, in May 1762, by Lord Bute, as head of the ministry. Newcastle declined a proferred pension, with the remark that if he could no longer serve he would not burden his country. In the Rockingham ministry, formed in 1765, he filled for a few months the office of Privy Seal. He died in August 1768.—His younger brother, HENRY PELHAM (1696–1754), took an active part in suppressing the rebellion of 1715, became Secretary of State for War in 1724, and was a zealous supporter of Walpole. In 1743 he was made head of a ministry as First Commissioner of the Treasury and Chancellor of the Exchequer. Events during his ministry were the war of the Austrian succession, the Jacobite rebellion of the '45, the successful financial bill of 1750 (see GEORGE II.), the reform of the calendar, and Lord Hardwick's Marriage Act. His father's ducal title descended to Henry, ninth Earl of Lincoln, whose great-grandson,

HENRY PELHAM-CLINTON, fifth Duke of Newcastle, and twelfth Earl of Lincoln, was born 22d May 1811, and educated at Christ Church, Oxford. He represented South Notts in parliament from 1832 to 1846, when he was ousted by the influence of his father, the fourth duke, for supporting Sir Robert Peel in his free-trade measures. He was a Lord of the Treasury in the brief Conservative administration of 1834–35, and First Commissioner of Woods and Forests in the Peel administration, 1841–46. He was then made Irish Secretary, but went out of office with his chief a few months afterwards. He succeeded to the dukedom in 1851, and returned to office in 1852, filling the post of Secretary of State for the Colonies in the Aberdeen government. The war with Russia broke out, and in June 1854 it was found necessary to create a Secretary of State for War, and the new office was assigned to Newcastle. The terrible sufferings of the British army before Sebastopol in the winter months of 1854 raised a storm of popular discontent, and when the House of Commons determined to inquire into the conduct of the war the duke resigned. Newcastle was Colonial Secretary in the second administration of Lord Palmerston, and held the seals with general approval from 1859 till his death, 18th October 1864.

Pelican (*Pelecanus*), a genus of birds comprising a family, Pelecanidæ, having a very long, large, flattened bill, the upper mandible terminated by a strong hook, which curves over the tip of the lower one; beneath the lower mandible a great pouch of naked skin is appended; the tongue is very short, and almost rudimentary; the face and throat are naked, the wings of moderate length, the tail rounded. The species are widely distributed, frequenting the shores of the sea, lakes, and rivers, and feeding chiefly on fish. Although birds of powerful wing, they are seldom seen at a great distance from land. All of them are birds of large size. They take their prey by hovering over the water, and plunging upon it when it appears. They often fly in large flocks, and the sudden swoop of a flock of pelicans at a shoal of fish is a striking and beautiful sight. They store up their prey in their pouch, from which they bring it out at leisure, either for their own eating or to feed their young. The pouch is capable of being wrinkled up into small size, and of being greatly distended. The Common Pelican (*P. onocrotalus*) is as large as a swan, white, slightly tinged with flesh colour, and, in old birds, the breast golden yellow. The quill-feathers are black, but are scarcely seen except when the wings are expanded. It is a native of the eastern parts of Europe and of many parts of Asia and Africa, and frequents both the seacoast and also rivers and lakes. It makes a nest of grass on the ground in some retired spot near the water, often on an island, and lays two or three white eggs. The parents are said to carry water to their young, as well as food, in their pouch. During the night the pelican sits with its bill resting on its breast. The nail or hook which terminates the bill is red; and it has been supposed that the fable of the pelican feeding its young with blood from its own breast originated in its habit of pressing the

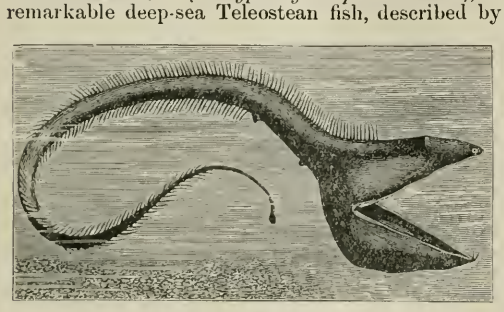
bill upon the breast in order the more easily to empty the pouch, when the red tip might be mistaken for blood. Another explanation is that the characteristic has been transferred to the pelican from the flamingo, which does discharge into the mouths of its young a bloody-looking secretion which it disgorges (see *Notes and Queries*, 1869, ii. p. 361). And long since Sir Thomas Browne in *Vulgar Errors* pointed out that the carvings



Pelican (*Pelecanus crispus*).

and pictures, ecclesiastical and heraldic, of the so-called pelican feeding its young with its own blood were by no means quite like a pelican, and noted that a like tale was told by the Egyptians of the vulture. The story, which was unknown to the classical writers, seems to have originated in Egypt; and the love of the vulture for its young was proverbial there (see *Academy*, 1884, i. p. 97). The Rufous-necked Pelican (*P. fuscus*) abounds in the West Indies and in many parts of America. Other species are found in other parts of the world, and in some places the number of pelicans is prodigious, particularly in some of the most southern parts of the world. See also HERALDRY, Vol. V. p. 664.

Pelican-fish (*Eurypharynx pelecanoides*), a remarkable deep-sea Teleostean fish, described by



Pelican-fish (*Eurypharynx pelecanoides*).

Vaillant in 1882. The body is somewhat eel-like, and is fringed on the dorsal and ventral middle line with spinous rays. It is the region of the jaws, however, which is most remarkable, the gape is so enormous. The fish probably engulfs small animals in whale-like fashion, but at the bottom of the sea instead of at the surface. Gill and Ryder discovered a similar form, *Gastrostomus bairdii*, in 1883, in which the mouth again suggests a pelican's pouch. The equally strange Saccopharyngidæ are perhaps allied, but the jaws are less enormous, and the animals are notable for swallowing fishes larger than themselves.

Pelion, the ancient name of a wooded mountain-range in Thessaly, extending along the east coast. According to the myth, the Titans, in order to scale Olympus, the abode of the gods, placed Ossa (q.v.) on the summit of Pelion, the highest peak (5310 feet) of the range. Its sides and summit have always been clothed with forests of oak, chestnut, beech, elm, plane, and pine; it was of Pelion timber that the Argo (see ARGONAUTS) was built. The Centaur Chiron had his home on this mountain.

Pélissier, AMABLE JEAN JACQUES, Duc de Malakhoff, Marshal of France, was born 6th November 1794, at Maromme, near Rouen, and, having passed successfully through the colleges of La Flèche and St Cyr, entered the army. He served on the staff in Spain in 1823, made the campaign of the Morea in 1828, joined the first expedition to Algiers in 1830 as major of cavalry, and in 1839 returned to Algeria with the rank of lieutenant-colonel. In 1845 he acquired an unenviable notoriety by suffocating more than 500 Arabs who took refuge in caves in the Dahra. By 1850 he had attained the rank of General of Division. On the outbreak of the Crimean war in 1855 he was given the command of the first corps, and soon succeeded Marshal Canrobert in the chief command before Sebastopol. On 8th September he stormed the Malakhoff, the key of Sebastopol, for which exploit he was rewarded with a marshal's baton, and on his return to France was created Duc de Malakhoff and a senator, and received a grant of 100,000 francs. In 1858 he came to London as the French ambassador, but resigned his post in the following year, and was named governor of Algeria, where he died on 22d May 1864. See Sir E. Hamley, *The War in the Crimea* (1891).

Pelitic Structure, in Geology, applied to rocks which have a texture like that of dried mud.

Pella, the ancient capital of Macedonia, and the birthplace of Philip II. and Alexander the Great, was situated in the midst of marshes, a few miles NW. of Thessalonica, which stood half-way between it and the head of what is now the Gulf of Saloniki. Its royal castle had wall-paintings by Zeuxis.

Pellagra (Ital. *pelle agra*, 'rough skin'), a disease, unknown prior to the first half of the 18th century, which is common among the peasantry of Northern Italy, and occurs also among the same class in Corfu, Roumania, the Landes and Gironde in France, and Oviedo and elsewhere in Spain. But the headquarters of the disease are in the northern and north central provinces of Italy; it is unknown to the south of Rome and in the islands. It is an error to describe pellagra as the result of poverty alone—to call it *il delirio della miseria*; it is clearly traceable to the use, as the staple diet, of damaged and unwholesome maize, gathered before it is ripe, and stored carelessly—often in cellars or pits—in its wet state. The disease makes its appearance in spring, in the form of a reddish-brown rash, which smarts painfully where exposed to the sun and air, as on the bare hands and feet; towards autumn this disappears, leaving, however, hard, dry spots on the skin, and returning with increased determination in the

following spring, and again in each successive year, till the skin becomes shrivelled and yellow, or even black in certain spots, and the body is reduced to a mummified state. A burning feeling in the mouth and bowels is an accompanying symptom, and profuse diarrhœa, along with a rapid wasting, and dropsy, is a frequent cause of death. As the disease progresses disorders relating to the nervous system gradually develop, and culminate in melancholy, imbecility, or mania; death often ensues from delirium, or the wretched patients drag out their life within the walls of an asylum. In Roumania 1·22, and in Corfu 3·2 per 1000 of the population is affected; in Italy in 1887 there were 3688 deaths from pellagra, or 2·04 per 1000 of the estimated population; but in 1881 the proportion was 4·8, and since then it has steadily decreased, in part owing to the number of hospitals built within late years for the special treatment of this disease. See the official report, *La Pellagra in Italia* (Rome, 1880).

Pellegrini, Carlo, caricaturist, was born at Capua in 1839, came to London in 1865, and from 1868 till his death on 22d January 1889 was the 'Ape' of *Vanity Fair*, the delineator of its inimitable series of cartoons of celebrities. Especially good was his statuette in red plaster of Mr Lowe standing on a match-box (1871).

Pellico, Silvio, an Italian poet, celebrated for his long and cruel imprisonment by the Austrians, was born 24th June 1788, at Saluzzo, in Piedmont, and was educated in Pignerol, where his father, Onorato Pellico, a lyric poet, had a silk-factory. In his sixteenth year he accompanied his sister Rosina (on her marriage) to Lyons, where he remained until Foscolo's *Sepolcri* awakened in him a strong patriotic feeling and an irresistible desire to return to Italy. Coming, about 1810, to Milan, he was warmly received by Ugo Foscolo and Vincenzo Monti, and became French tutor in the military school. His tragedies of *Laodamia* and *Francesca da Rimini* gained him an honourable name amongst Italian poets. He also translated the *Manfred* of Byron, with whom he had become acquainted. He lived in great intimacy with the most eminent patriots and authors of liberal views, and took an active part in a periodical called *Il Conciliatore*, which after a time was suppressed on account of its liberal tone. In 1820 he was arrested on a charge of Carbonarism, and sent to the prison of Sta Margherita, and afterwards to the Piombi at Venice. After two years' imprisonment he was condemned to death, but had his sentence commuted to fifteen years' imprisonment, and was carried to the fortress of Spielberg near Brünn; he was, however, liberated in August 1830. During his imprisonment he had written two other dramas; and afterwards he published an account of his sufferings during his ten years' imprisonment, under the title *Le mie Prigioni* (Paris, 1833), which has been translated into many languages, and has made his name familiar where it would not have been known on account of his poetry. Pellico's health, never robust, was permanently injured. The Marchioness of Barolo received him into her house at Turin as her secretary. Pellico subsequently published numerous tragedies and other poems, and a little catechism on the duties of man. He died January 31, 1854. See the Life by Chiala (Italian, 1852), and that by Bourdon (Paris, 8th ed. 1885).

Pellitory, or Wall-pellitory (*Parietaria*), a genus of plants of the natural order Urticeæ, having both unisexual and hermaphrodite flowers on the same plant, the perianth of both kinds 4-fid. The Common Pellitory (*P. officinalis*), which grows on old walls and heaps of rubbish in Britain and many parts of Europe and Asia, is a perennial herb, with erect or prostrate stems, ovate leaves, and inconspicuous flowers. It sometimes attracts attention from the manner in which the pollen is copiously discharged in hot summer days by an elastic movement of the filaments. It is an old domestic remedy as a diuretic, emollient, and refrigerant, but only as a diuretic is it really serviceable, a property which depends on the nitre it contains.

Pellitory (*Parietaria officinalis*).

Pellitory of Spain (*Anacyclus pyrethrum*) is a plant of the natural order Compositæ, of a genus nearly allied to Camomile (q.v.), a native of the Levant and of Barbary, and cultivated to some extent in Germany and other countries. The root is spindle-shaped and fleshy, and when dried is about the thickness of the little finger, inodorous, breaking with a resinous fracture. It has a very peculiar taste, slight at first, but becoming acidulous, saline, and acrid, with a burning and tingling sensation in the mouth and throat, which continues for some time. It is sometimes used in medicine. It is a powerful local irritant. The plant cultivated in Germany has more slender roots than that of the Levant.

Pelop'idas, a celebrated Theban general, of noble descent, noted among his fellow-citizens for his disinterested patriotism. The inviolable friendship between himself—one of the richest men in Thebes—and Epaminondas—one of the poorest—is among the most beautiful things recorded in Greek history. In 382 B.C. he was driven from Thebes by the oligarchic party, who were supported by the Spartans, and was forced to seek refuge at Athens, whence he returned secretly with a few associates, 379 B.C., and recovered possession of the Cadmeia, or citadel, slaying the Spartan leader, Leontiades, with his own hand. Plutarch gives us a vivid picture of the adventurous exiles gliding quietly in disguise into the city on a winter afternoon, amid bitter wind and sleet. Having been elected Bœotarch, in conjunction with Melon and Charon, he set about training and disciplining his troops, so that they soon became as formidable as the Lacedæmonians, and were successful in several small encounters with the latter. His 'sacred band' of Theban youth largely contributed to the victory of Epaminondas at Leuctra (371 B.C.), but failed in a subsequent attack on Sparta itself. In the expedition of the Thebans against the cruel tyrant, Alexander of Pheræ (368 B.C.), Pelopidas was, after several important successes, treacherously taken prisoner, when in the character of an ambassador, but was rescued by Epaminondas in the expedition of the following year. He was then sent to Susa, as ambassador from Thebes, to counteract the Spartan and Athenian intrigues going on at the court of Persia, and bore himself very nobly whilst there. His diplomacy was successful. In 364 B.C.

a third expedition was planned against Alexander of Pheræ, who, as usual, was threatening the Thessalian towns. The command was given to Pelopidas, and in the summer he marched into Thessaly, where he won the battle of Cynoscephalæ, but was himself killed while too eagerly pursuing the foe.

Peloponnesus ('the isle of Pelops'), now called the Morea (q.v.), a peninsula which formed the southern part of ancient Greece, Hellas Proper being situated to the northward of the isthmus on which stood the city of Corinth. See GREECE. The whole area is less than 9000 sq. m. Among its most important cities were Sparta and Argos. Sparta acquired after the Messenian war a decided supremacy over the other states, and disputed the supremacy with Athens in a war of almost thirty years' duration (431–404 B.C.)—the famous Peloponnesian war, of which the history has been written by Thucydides.

Pelops, in Greek Mythology, the grandson of Zeus, and the son of Tantalus, was slain by his father, and served up at an entertainment which he gave to the gods, in order to test their omniscience. They were not deceived, and would not touch the horrible food; but Demeter, absorbed with grief for the loss of her daughter, ate part of a shoulder without observing. The gods then commanded the members to be thrown into a cauldron, out of which Clotho brought the boy again alive, and the want of the shoulder was supplied by an ivory one. According to the legend most general in later times, Pelops was a Phrygian, who, being driven by Ilos from Sipylos, came with great treasures to the peninsula which derived from him the name of Peloponnesus, married Hippodamia, obtained her father's kingdom by conquering him in a chariot-race, and became the father of Atreus, Thyestes, and other sons. But in what appear to be the oldest traditions he is represented as a Greek, and not as a foreigner. He was said to have revived the Olympic games, and was particularly honoured at Olympia.

Pel's Fish-owl (*Scotopelia peli*), so named from having been first discovered by Mr Pel, the Dutch commandant at Elmina, is found in West Africa from Senegambia to Gaboon, and in the Zambesi region in South-east Africa. It measures about 2 feet in length; its wing is 16½ inches long. Its colour above is a deep rufous bay crossed with numerous irregular bars of black; the wing is similarly barred; the under surface of the body is light bay with heart-shaped bars of black; the bill is of a dark-blue lead colour, and the iris is dark brown. The birds from the Zambesi are a little larger than those from West Africa. The natives regard this owl as a fetish bird possessing the power of destroying whatever it looks on; and curiously enough its presence in more than one locality has been followed by an outbreak of disease among domestic animals. See the *Ibis* for 1859, p. 445.

Peltier Effect. See ELECTRICITY, Vol. IV. p. 276.

Peltry, a general term applied to the trade in skins of wild animals, and to the skins themselves. It is understood to mean only skins undressed, except by drying, and chiefly those which, when dressed, are called furs. See FURS.

Pelusium, the Greek name of an ancient Egyptian city, situated at the north-eastern angle of the Delta, and important as the key of Egypt on the Asiatic side. The eastern mouth of the Nile derived from it the epithet Pelusiac. Its identity with Sin of the Old Testament and the Greek Saïs is doubtful. The *Ostium Pelusiacum* was choked up with sand as long ago as the 1st century B.C., and the whole district is a wilderness of sand and marshes.

Pelvis. This term is used to indicate one of the chief divisions of the skeleton. It consists of the sacrum, coccyx, and the innominate or haunch bones. Each of the latter originally consisted of three parts—ilium, ischium, pubis—which have become fused together. By the articulation of the pubic bones in the middle line anteriorly the innominate bones form the anterior and lateral aspects of the pelvis. Wedged in between them posteriorly are the sacrum and coccyx. Various powerful ligaments give support to and maintain the pelvic bones in position. Notwithstanding the importance of this part of the skeleton, the ancient Greek physician had no word whereby to designate it, and both Greek and Roman associated the sacrum and coccyx with the vertebral column, and the innominate bones with the lower extremities.

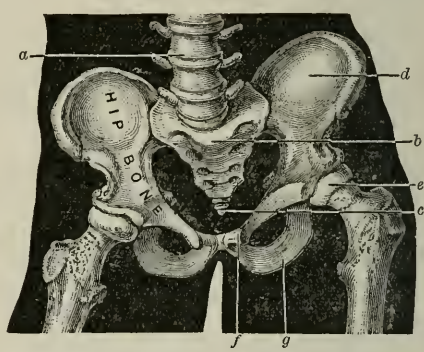


Fig. 1.—Adult Human Pelvis, *in situ*:
a, lumbar vertebra; *b*, sacrum; *c*, coccyx; *d*, ilium; *e*, head of femur in acetabulum; *f*, pubis; *g*, ischium.

The pelvis is divided into two parts by a plane which extends from the upper margin or promontory of the sacrum to the upper margin of the articulation between the two pubic bones—i.e. the symphysis pubis. On the inner surface of each innominate bone a line may be traced from the sacral promontory to the symphysis pubis. This is named the ilio-pectineal line, and it helps to complete the circumference of the plane which divides the pelvis into two parts. The space *above* this plane lies mostly between the expanded iliac bones. It belongs to the abdomen proper, and is named the *false* pelvis. The space below the level of the sacral promontory and ilio-pectineal lines is called the *true* pelvis, and certain descriptive terms are employed in connection with it. Thus the plane which separates it from the false pelvis is called the *inlet* or *brim* of the true pelvis. Its inferior circumference or *outlet* extends from the tip of the coccyx to the inferior border of the pubic symphysis, and from the one ischial tuberosity to the other. Between the ischial tuberosities in front and extending forwards to the symphysis there is the *subpubic* arch. The space between the *inlet* and the *outlet* is named the *cavity* of the true pelvis. The measurements of the true pelvis are made along certain definite lines which are applicable to the brim, the cavity, or the outlet. These are (1) the *antero-posterior* or conjugate diameter—i.e. from the mesial line in front to the mesial line behind; (2) the *transverse* or widest diameter; (3) the *oblique* diameters—right and left. These extend from the articulation between sacrum and ilium on one side to the farthest point on the opposite side of the mesial plane. In the erect attitude of the body the plane of the brim of the true pelvis forms

an angle with the horizontal which varies from 60° to 65°. Thus the weight of the upper part of the body which is communicated to the sacrum is directed downwards and transmitted through the innominate bones to the heads of the femora, and so to the inferior extremities. In addition to the ligaments, muscles, blood-vessels, and nerves which constitute the soft parts of the pelvis, there are certain special organs which are present in both sexes, and others which are peculiar to each sex. Thus, of those common to both sexes, there are the urinary bladder and the rectum. The urinary bladder is placed behind the symphysis pubis, and only rises out of the pelvis into the abdomen when considerably distended. The rectum—a name applied to that part of the alimentary canal which passes through the pelvis—is placed on the front of the sacrum and coccyx, a short distance below which it terminates in the anus. The lower end of the rectum is supported by two muscles—the *levatores uni*—which surround it so completely as to form a floor or diaphragm for the pelvis. In addition to these organs there are others which are characteristic of the sexes. In the male we have the *vesiculæ seminales* and the *prostate gland*—the latter surrounding the outlet of the urinary bladder. In the female we have the *uterus*, *ovaries*, and their various appendages. The diverse functions of these organs have led to corresponding and well-marked differences in the size and form of the osseous pelves of the sexes. In the female the bones are more slender, and the muscular impressions less distinct. The true pelvis has a greater breadth and capacity, but its perpendicular depth is less. The *inlet* is more nearly circular; the ischial tuberosities are wider apart, and the subpubic arch is much wider. All of these differences indicate special modifications in connection with the necessities of child-bearing. Although the depth of the cavity of the true pelvis steadily increases from childhood to puberty, yet the characteristics of the sexes are discernible even at birth.

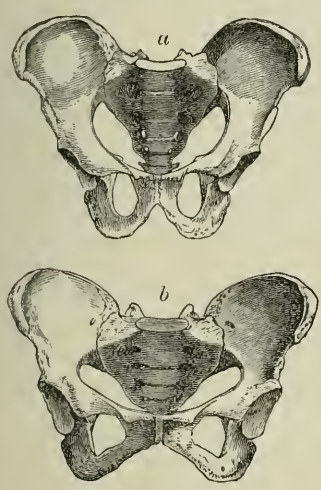

Fig. 2.
a, adult male, and *b*, female pelvis.

But not only does the pelvis display features which are characteristic of sex; it also presents characters which are peculiar to individual races of mankind. In this field of study a great amount of valuable work has been contributed by Sir William Turner of Edinburgh University, and embodied in the reports of the *Challenger* expedition. In determining those features peculiar to race numerous measurements have been made, mostly in relation to the cavity of the true pelvis with its brim and outlet; but many of the external dimensions of the entire pelvis have also been noted, as well as the dimensions of individual bones. One of the most valuable of the external measurements is the comparison between the maximum height and breadth of the entire pelvis. A common result is obtained by the following formula, $\frac{\text{height} \times 100}{\text{breadth}}$, which establishes what is called a *breadth-height index*. Another index of great importance is the result of a comparison between the *conjugate* and *transverse* diameters at the brim of the pelvis. This is named the *pelvic* or *brim index*, and is obtained by the formula, $\frac{\text{conj. diam.} \times 100}{\text{transverse diam.}}$. The measurements are usually recorded in millimètres. As the result of numerous measurements Sir William Turner has devised a classification of pelves based upon the relation of the conjugate and transverse diameters at the brim of the true pelvis—i.e. upon the *brim index*. Thus, those pelves in which the conjugate diameter of the brim is either longer than the transverse or closely approaches it are named *dolichopellic* (*pellis*, the Greek equivalent of the Latin *pelvis*, 'a basin;' and *dolichos*, 'long'), and in these the brim index is above 95. When the transverse diameter of the brim greatly exceeds the conjugate they are named *platypellic* (*platys*, 'wide'), and the brim index is below 90. In cases where the transverse diameter is not greatly in excess of the conjugate—i.e. where the brim index varies between 90 and 95, both inclusive—the term *mesatipellic* (*mesaitatos*, 'middlemost') is applied. Grouping the pelves under these headings we find that such races as Australians, Bushmen, Hottentots, Kaffirs, Malays, Andaman Islanders, &c. are *dolichopellic*. Negroes, Tasmanians, New Caledonians, &c. are *mesatipellic*. British, French, Germans, Europeans generally, natives of India, Chinese, American Indians, &c. are *platypellic*. These results are obtained from the examination of male pelves, since, as we have already seen, the female pelvis is modified in its diameters in relation to the special requirements of sex.

If now we compare the human pelvis with that of the lower mammalia, we shall find that the human pelvis is characterised by breadth and shallowness and the great capacity of the true pelvis. When, therefore, the conjugate diameter at the brim of the pelvis is longer than the transverse—i.e. when the pelvis is dolichopellic—an approach is made to the condition which prevails even to a greater extent among the lower animals, and it is 'a degraded or animalised arrangement' as compared with platypellic pelvis of Europeans.

We have seen that in man the weight of the trunk is transmitted to the lower limbs through the pelvis, whereas in quadrupeds the downward pressure of the weight of the trunk is differently disposed. Doubtless, therefore, the *attitude* has great influence in controlling the expansion of the pelvis in the transverse diameter when the parts are young and plastic. It may therefore be owing to the habits and mode of life of the black races in their aboriginal state that their pelves approach the lower type. Take, for example, the aboriginal Australian who sits on the ground embracing his knees with his arms, or any of the savages whose favourite attitude is 'squatting'—i.e. sitting down with the body bent forward and the buttocks resting on the heels; or again, when in pursuit of game a stooping or crouching attitude is adopted. In all these positions the pressure upon the sacrum and pelvis is diminished, and there is a tendency to approximate the conditions to those of the anthropoid apes, while the white man on the other hand preserves the erect attitude whether standing, sitting, or walking.

Pemba, a coral island off the east coast of Africa, lies 50 miles NE. of Zanzibar Island, has a length of 46 miles and a breadth of 4½; area, 372 sq. m. There are numerous bays on the east coast; on one of them stands the chief town, Chaka. The inhabitants, 50,000 in number, rear cattle and trade in rice, cloves, and ebony, all products of the

island. It is under the same administration as the rest of the Zanzibar Protectorate.

Pembina, a small village, the capital of Pembina county, North Dakota, on the Red River of the North, at the mouth of the Pembina River. By rail it is 68 miles SW. of Winnipeg and 293 NW. of St Paul; and its position makes it worthy of notice, as on the north it marks the boundary line between Manitoba and the United States, while on the east only the Red River separates it from Minnesota.

Pembroke, the county town of Pembrokeshire, on a navigable creek of Milford Haven, 9 miles W. of Tenby and 80 W. by N. of Cardiff. On the extremity of the ridge on which the town is built stands Pembroke Castle, founded in 1094 by Arnulf de Montgomery, a very imposing ruin, with a Norman keep 75 feet high and 52 in diameter. Beneath is a huge natural cavern, 70 by 50 feet. The birthplace of Henry VII., this castle in 1648 was taken by Cromwell after a six weeks' siege. Monkton Priory, with its roofless Decorated choir, is another interesting structure. The Pembroke district of boroughs, returning one member, comprises Pembroke, Milford, Tenby, Wiston, and also (since 1885) Haverfordwest, Fishguard, and Narberth. Pembroke for more than four centuries has given the title of earl to the House of Herbert (q.v.). At Pembroke Dock, or Pater, 2½ miles north-west, is the naval dockyard and arsenal, established in 1814. It embraces an area of 70 acres, and since 1861 has been fortified at a cost of more than a quarter of a million. Pop. of Pembroke (1861) 15,071; (1881) 16,339; of Pembroke Dock (1861) 10,190; (1891) 10,481.

Pembrokeshire, a maritime county of South Wales, the westernmost of the Principality. Measuring 30 by 25 miles, it has an area of 611 sq. m., or 391,181 acres, of which three-fourths is arable. The coast-line is much of it rugged and precipitous; and inland the surface is undulating, green hills alternating with fertile valleys, and attaining a maximum altitude of 1754 feet in the Precelly range, which traverses the north of the county from east to west. Rivers are the Teifi, separating Pembrokeshire from Cardigan, and the East and the West Cleddau. The rocks are largely Silurian; the soil varies much in quality; and coal, slate, lead, and iron have been worked. St David's Cathedral and half-a-dozen mediæval castles make up the antiquities with Ogam inscriptions, neolithic implements, and Roman coins. At Haverfordwest and Tenby a colony of Flemings was established in 1107. They adopted the English tongue; and Pembrokeshire, or 'Little England beyond Wales,' is now over more than half its area inhabited by an English-speaking population, although it is the remotest of all the Welsh counties. It was harried by Owen Glendower in 1405; and on 22d February 1797 it witnessed the last French invasion, when 600 regulars and 800 gaol-birds landed near Fishguard, only to surrender unconditionally to some militia and yeomanry under Lord Cawdor. Pembrokeshire returns one member. Pop. (1801) 56,280; (1841) 88,044; (1881) 91,824; (1891) 89,125. See Fenton's *Historical Tour through Pembrokeshire* (1811).

Pemmican. This was originally a North American Indian preparation only, but it was introduced into the British navy victualling-yards in order to supply arctic expeditions with an easily-preserved food, containing the largest amount of nutriment in the smallest space. As made by the Indians, it consists of the lean portions of venison dried in the sun, or wind, and then pounded into a paste and tightly pressed into cakes; sometimes a few fruits of *Amelanchier ovata* are added to improve the flavour. It will keep for a very long time uninjured. That made for the arctic voyagers was chiefly of beef. In making pemmican it is necessary to remove the fat completely.

Pemphigus, or Pompholyx, belongs to that order of skin diseases which is characterised by an eruption of large vesicles, filled with serous fluid, and known as *bullæ*. The disease occurs both in the acute and in the chronic form. In a mild case of acute pemphigus, bullæ, or blisters, from the size of a pea to that of a chestnut, appear in succession (chiefly on the extremities), and having continued three or four days break, form a thin scab, and soon heal, unaccompanied with febrile or inflammatory symptoms. In severe cases there is considerable constitutional disturbance, the bullæ are larger, and the scabs heal with difficulty. The chronic form differs mainly from the acute by its prolonged continuance. The acute variety chiefly affects children, and has been ascribed to dentition, errors of diet, &c.; while the chronic form chiefly attacks aged persons, and is probably due to debility and impaired nutrition. The acute form usually requires nothing but cooling medicines and diet, and mild local dressings, such as simple cerate, to protect the raw surfaces from exposure to the air. In the chronic form a nutritious diet, with the judicious use of tonics (iron, bark, &c.), is most commonly successful. In obstinate cases arsenic is sometimes of use.

Pen, an instrument for writing with a fluid ink. When the Egyptians, Greeks, Romans, and some other ancient nations wrote upon papyrus or parchment they used a reed pen (Lat. *calamus*), and when they used tablets of wood or stone covered with wax they wrote upon them with a pointed stylus of bronze, bone, or other material. Some of these ancient reed pens have been preserved. One, now at Naples, was found in a papyrus at Herculaneum. Reed pens are still the only kind used by the natives of Persia and some neighbouring countries. A metal pen does not suit their mode of writing. These reed pens are pointed much in the same way as quills, and are made from the reeds or stems of *Phragmites communis*, which is also a British plant, *Erianthus Ravennæ*, and probably other species of this genus. The Chinese and Japanese write with a small brush or hair-pencil. Quills are known to have been used for writing with as early as the 7th century of our era, but long after that reed pens also were employed in European countries.

Metal pens were in use, but probably only to a very limited extent, among the ancient Romans. In the museum at Naples there is a bronze pen, nibbed like a modern steel pen, which was found at Pompeii. Another of a somewhat different shape was discovered at Herculaneum. Bronze and silver writing pens appear to have been occasionally made in the middle ages, but there is little doubt these were more curiosities than articles in general use, and the same may be said of all metallic pens of more recent date, sometimes referred to in books, until we come to the beginning of the 19th century. For centuries before that quills were universally employed among western nations, and in schools steel pens were only very partially substituted for them till about 1840.

Perhaps the earliest English metallic pens of which we have any certain knowledge were some made in 1780 by Mr Harrison, split-ring maker, Birmingham, for Dr Priestley. They were of sheet-steel, formed into a tube and filed into shape, the joining of the metal making the slit. Brass pens were also made in England before the end of last century; one of these seems to have been in the Strawberry Hill collection of art objects and

curiosities (Walpole's), which was sold in London in 1842. In the early part of the century various plans were tried to produce pens more lasting than ordinary quills. The quills were pointed with metal, and pens constructed of horn and tortoise-shell had small pieces of diamond and other hard gems embedded in them by pressure. Another plan was to attach gold to their points. Such pens were of course too costly for general use. Barrel pens of steel made by Mr Wise were on sale in London in 1803, but these, too, were high in price, and did not take the market. The first English patent for the manufacture of steel pens is that of Bryan Donkin in 1803. A patent, the first of its kind in America, was granted in 1810 to Peregrine Williamson of Baltimore for the manufacture of metallic pens. Steel pens of the barrel type were being made in 1815 by Sheldon of Sedgley, the price being 18s. per dozen. By 1820 the number of manufacturers had increased. To Mr James Perry belongs the credit of bringing steel pens into general use. He began pen-making at Manchester in 1819, using the best Sheffield steel (from Swedish charcoal iron) for the purpose. Perry removed to Red Lion Square, London, and had developed the pen trade with remarkable energy before the prominent Birmingham makers, Mitchell, Gillott, and Mason, caused a revolution in the trade by machine-made pens. He took out a patent for a new method of making pens in 1830, from hard, thin, elastic metal, and a 'length of slitted or cleft space' scarcely exceeding that of quill-pens; and he made other improvements in 1832. The greatest improvement in the manufacture was the adoption of the screw handpress for the cutting out of pens, enabling the manufacturer to supply them cheaply and in quantities. At first the method of slitting pens by means of a press was kept a profound secret by Gillott and Mason. To Mr John Mitchell, Birmingham, has been assigned priority in this invention. Sir Josiah Mason made barrel pens in 1828, and 'slip' pens for Perry in 1829. At the end of 1875, when Sir Josiah Mason retired from his business, his output exceeded 32,000 gross weekly. To Mitchell, Gillott (whose patent is dated 1831), and Sir Josiah Mason chiefly belongs the credit of first making steel pens by machinery, thus enabling them to be sold cheaply and to become articles of common use.

An ordinary pen looks a simple enough instrument, but before it assumes its present appearance it has to go through some sixteen different processes. Birmingham is the great seat of the steel-pen trade. The steel of which the pens are made comes from Sheffield, and is in sheets 6 feet long and 1 foot 5 inches wide. It is first cut into strips of convenient width; next it is annealed, and rolled to the requisite thickness, when it is found to have trebled its original length and to have acquired a bright surface from the action of the rollers. The 'blanks' or first shape of the pen are now cut out by means of a press; next comes the operation of *marking* or stamping the name on the pen, then *piercing;* but before they can be formed into the shape of a pen they require to be softened by *annealing*. They are freed from dust and grease, placed in round pots, which are again enclosed in larger ones, are covered with charcoal dust, put into a muffle or iron box, heated to a dull red, and then allowed to cool. The pens are next *raised* or formed into the required shape by a blow from a screw-press fitted with a punch and a die. Then they are *hardened*. This is done by arranging them in thin layers in covered iron pans of a round shape, which are heated to a bright redness in a muffle. The contents of the pans are next emptied into a bucket, immersed in a tank of oil, and transferred to a perforated cylinder, which, being quickly rotated, drains off the oil. The pens are still greasy and as brittle as glass, and in order to cleanse them they are again placed in perforated buckets and plunged into a tank of boiling soda-water. They are next tempered, or softened, by enclosure in an iron cylinder which is kept revolving over a charcoal fire until the requisite degree of softness is attained. The pens have been blackened by this operation; they are next *scoured* by being dipped into a tub of diluted sulphuric acid, and then put into iron barrels containing water and material made from broken and finely-ground annealing pots. The barrels are kept revolving for five, or sometimes eight, hours; then the pens are subjected to a second process of scouring in barrels filled with dry material of the same kind; and then to a third process in which dry sawdust is the scouring or cleaning agent. The pens have now acquired a bright, silver tone, and the points have been rounded. They have then to be ground between the pierced portion and the point; this is done on a small revolving solid wheel or 'bob' made of wood, covered with leather, and coated with emery-powder. Next comes the operation of *slitting*, which is cleverly accomplished by a cutting-press, but, the edges of the slit being sharp, the pens are again polished in revolving barrels. They are now coloured and varnished; the colouring is done in a copper or iron cylinder over a coke fire; if to be lacquered they are placed in a solution of shellac. Afterwards the spirit is drained off, the pens are placed in wire cylinders, and kept revolving until the lacquer is dry. Next the pens are spread on iron trays and put into an oven, the heat of which spreads the lacquer evenly over the surface. Girls now look over the pens, throw aside the faulty ones, and the good ones are packed into boxes ready for sale.

How the trade has grown may be seen from the fact that in 1839 steel pens were almost unknown; in 1849 the trade was a leading industry in Birmingham; there were twelve factories employing about 2000 men, women, and girls, the weekly output of pens being stated at 65,000 gross. The output in 1866 had increased to 98,000 gross weekly; and about 4000 people were employed in all departments. In 1886 the weekly average of pens manufactured was about 160,000 gross, or twenty-two million pens. There were four pen-works in the United States at the same date, only one of which was of importance; three in France; and one in Germany. The most successful recent patents in connection with pens have been those dealing with points which are turned up or turned down, thickened or 'planished,' for smooth writing. A leading pen-maker has a catalogue containing 5000 varieties of pens, while it has been estimated that no fewer than 100,000 different shapes and sizes are in the market. All the pen-makers now make pen-holders, and Josiah Mason has related that he made the first stick pen-holders for Perry in 1832, and for Gillott in 1835.

Pens are also made of silver, platinum, and aluminium bronze. They have also been made of vulcanite. The gold pen, which is incorrodible with ink, was also made in Birmingham for Mordan and others. Made in the United States as early as 1836, it has become a speciality there: one American firm manufactures 100,000 every year. The gold pen goes through no less than forty-five different processes, from the gold-bar, purchased from the United States Assay Office, which is alloyed, to the highly-finished article of commerce. To give firmness to the point of the pen it is pointed with iridium. The United States imports over half a million gross of steel pens annually, and manufactures one and a half million gross, at Camden, Meriden, and Philadelphia. The steel used is

mostly imported from Birmingham. In the stylograph, or fountain pen, the nib is dispensed with, a finely-tapered point connecting with the barrel containing the ink; the first fountain pen was brought out in 1848. See Bunce's *Josiah Mason* (1890), which contains a sketch of the history of the steel-pen trade.

Penal Laws. See CATHOLIC EMANCIPATION, IRELAND.

Penal Servitude is a sentence for criminal offences which has been introduced in lieu of the sentence of transportation beyond the seas. See PRISONS.

Penance (Lat. *pœnitentia*), in Roman Catholic theology, means both the sorrow for sin and also the sacrament by which absolution is conveyed. It means also the voluntary or accepted self-inflicted punishment by which a repentant sinner manifests his sorrow for sin, and seeks to atone for the sin, and to avert the punishment which, even after the guilt has been remitted, may still remain due to the offence. Penance is believed in the Roman Catholic Church to be one of the sacraments of the New Law. It will be necessary to explain it briefly both under its relations as a sacrament and as a private personal exercise.

Penance as a state of mind is simply sorrow for evil-doing, accompanied with a purpose of amendment. Penance is the fruit or the manifestation of this sorrow, and it is commonly accompanied or expressed by some of those external acts which are the natural manifestations of any deep sorrow, either negative, as the neglect of ordinary attention to dress, to the care of the person, to the use of food, or positive, as the direct acts of personal mortification and self-inflicted pain, such as fasting, wearing haircloth, strewing the head with ashes, watching of nights, sleeping on hard boards, &c. Such manifestations of sorrow, whether from motives of religion or from merely natural causes, are common among the Eastern races, and are frequently alluded to in the Scriptures. In the personal practice of the early Christians penance found a prominent place, and the chief and acknowledged object of the stated Fasts (q.v.), and other works of mortification which prevailed, was that of penitential correction, or of the manifestation of sorrow for sin.

A still more striking use of penance, however, in the early church, was the disciplinary one; and this, in the Roman Catholic view, is connected with the sacramental character of penance. Any discussion of this purely theological question would be out of place here, and it will be enough to state briefly that Roman Catholics number penance among the Seven Sacraments, and believe it to be of direct divine institution (Matt. xviii. 18; John xx. 23; 1 Cor. v. 5). The *matter* of this sacrament consists, in their view, of the three acts of the penitent—contrition, or heartfelt sorrow for sin, as being an offence against God; confession, or detailed accusation of one's self to a priest approved for the purpose; and satisfaction, or the acceptance and accomplishment of certain penitential works, in atonement of the sin confessed. The *form* of the sacrament is the sentence of absolution from sin pronounced by the priest who has received the confession, and has been satisfied of the penitential disposition of the self-accusing sinner. In all these points, of course, they differ from Protestants. Even in the apostolic times the practice prevailed of excluding persons of scandalous life from the spiritual fellowship of the Christian community (see EXCOMMUNICATION); and, without attempting to fix the date, it may be stated as certain, from the authority of Tertullian and other writers, that from a very early time the persons so excluded were subjected to certain penitential regulations. The class of offenders so treated were those who had been notoriously guilty of the grievous crimes of idolatry or apostasy, murder, adultery, and other scandalous offences. The period of penitential probation differed in different times and places, but in general was graduated according to the enormity of the sin, some going so far in their rigour (see NOVATIAN) as, contrary to the clearly-expressed sense of the church, to carry it even beyond the grave. In the earlier ages much depended upon the spirit of each particular church or country; but about the 4th century the public penitential discipline assumed a settled form, which, especially as established in the Greek Church, is so curious that it deserves to be briefly described. Sinners of the classes already referred to had their names enrolled, and were (in some churches, after having made a preliminary confession to a priest appointed for the purpose) admitted, with a blessing and other ceremonial, by the bishop to the rank of penitents. This enrolment appears to have commonly taken place on the first day of Lent. The penitents so enrolled were arranged in four grades, called—1. (Gr. *proskluiontes*, Lat. *flentes*) 'Weepers;' 2. (Gr. *akroōmenoi*, Lat. *audientes*) 'Hearers;' 3. (Gr. *hypopiptontes*, Lat. *prosternentes*) 'Prostraters;' 4. (Gr. *systantes*, Lat. *consistentes*) 'Standers.' Of these classes the first were obliged to remain outside of the church at the time of public worship, and to ask the prayers of the faithful as they entered. The second were permitted to enter and to remain in the place and during the time appointed for the Catechumens (q.v.), but, like them, were required to depart before the commencement of the solemn part of the Liturgy (q.v.). The third were permitted to pray with the rest, but kneeling or prostrate, and for them were prescribed many other acts of mortification. The fourth were permitted to pray with the rest in a standing posture, although apparently in a distinct part of the church; but they were excluded from making offerings with the rest, and still more from receiving the communion. The time to be spent in each of these grades at first differed very much according to times and circumstances, but was afterwards regulated by elaborate laws, called penitential canons. Still it was in the power of the bishop to abridge or to prolong it; a power the exercise of which is connected with the historical origin of the practice of Indulgence (q.v.). Of these four grades the first two hardly appear in the Western Church. It is a subject of controversy whether, and how far, this discipline was extended to other than *public* sinners; but it seems certain that individuals, not publicly known as sinners, *voluntarily* enrolled themselves among the penitents. All four grades wore a distinguishing penitential dress, in which they appeared on all occasions of public worship, and were obliged to observe certain rules of life, to renounce certain indulgences and luxuries, and to practise certain austerities. In some churches they were employed in the care of the sick, the burial of the dead, and other of the more laborious works of charity. The penitent, in ordinary cases, could only be restored to communion by the bishop who had excluded him, and this only at the expiration of the appointed time, unless the bishop himself had shortened it; but in case of dangerous illness he might be restored, with the condition, however, that if he recovered from the illness the whole course of penance should be completed. The reconciliation of penitents took place commonly in Holy Week, and was publicly performed by the bishop in the church, with prayer and imposition of hands. It

was followed by the administration of communion. If any of the clergy were guilty of a crime to which public penance was annexed, they were first deposed from the rank of the clergy, and then subjected to the ordeal, like the laity themselves. This public discipline continued in force with greater or less exactness in the 5th, 6th, and 7th centuries, gradually, however, being replaced by semi-public, and ultimately by private penance. In the 11th and 12th centuries the public penance had entirely disappeared. The nature and origin of *private penance* is a subject of controversy between Catholics and Protestants; the former contending that it had existed from the first, and that it held the same place even in the ages of public penance for *secret sins* which the public penance did for public offences. At all events, from the date of the cessation of the public discipline it has existed universally in the Roman Church. The priest, in absolving the penitent, imposes upon him the obligation of reciting certain prayers, undergoing certain works of mortification, or performing certain devotional exercises. These acts of the penitent are held to form an integral part of the sacrament of penance. See CONFESSION; and Morinus, *De Pœnitentiâ* (1651).

By Protestant churches penance is not recognised; yet a confession was made and a penance inflicted publicly in a church at East Clevedon in Somersetshire in 1882; and there is a curious letter from Dr Pusey to Mr Hope-Scott, then abroad (1844), desiring him to procure a 'discipline' and 'send it by B. What was described to me was of a very sacred character: five cords each with five knots, in memory of the five wounds of our Lord. . . . I should be glad to know also whether there were any cases in which it is unsafe—e.g. in a nervous person.' An approach to the Roman Catholic polity on the subject was in use among the English Puritans of the 17th century, and more particularly in the Church of Scotland during that and the succeeding century, when it was common 'to make satisfaction publicly on the Stool of Repentance' (q.v.). In Ayrshire the kirk-sessions were accustomed regularly to provide sackcloth suits for ecclesiastical offenders as late as 1781; a heinous breach of the seventh commandment might involve the penitents' standing in the 'public place of repentance' in church, arrayed more or less completely in sackcloth, every successive Sunday for six months on end (see Edgar's *Old Church Life in Scotland*, 1885). It does not seem to have occurred to the Reformers or their more immediate successors in the Protestant churches that their system of discipline, with its public rebukes and enforced humiliations of various kinds, was liable to be interpreted in a sense very different from that of a mere expression of sorrow for sin; but the belief is now very general among the most zealous adherents of their doctrinal opinions that in all this they adopted practices incongruous with their creed, and in harmony rather with that of the Church of Rome. Nor do they seem to have perceived that Church Discipline (q.v.), in its proper sense, as relating to ecclesiastical rights and privileges, is wholly distinct from the imposition of penalties by churches or church courts. Penitential humiliations, imposed by ecclesiastical authority, are now no more in favour where church discipline is most strict than where the utmost laxity prevails. The commutation of penalties deemed shameful, for a fine to the poor of the parish, was an abuse once prevalent in Scotland, but never sanctioned by the higher ecclesiastical authorities.

Penang (*Pulo Pi'nang*, 'Betel-nut Island'), the official but less used name of which is PRINCE OF WALES ISLAND, one of the British Straits Settlements (q.v.), lies at the northern extremity of the Strait of Malacca, 2 to 10 miles from the west coast of the Malay Peninsula, and 360 miles NNW. of Singapore. Length, 15 miles; breadth, 5 to 10 miles; area, 107 sq. m., three-fifths being hilly. A sanatorium crowns the highest point, 2920 feet above sea-level. The whole is covered with forest and vegetation, cocoa-nut and areca palms predominating. In the low lands the thermometer ranges from 70° to 95°, and at the sanatorium from 60° to 75°. The rainfall averages 111 inches a year. Penang is a great shipping centre for the products of the native states of the Malacca Peninsula. The value of the commerce of Penang has greatly increased of late years. In 1888 the imports and exports combined reached a total value of £15,425,458; in 1896-98 the annual value of imports alone exceeded £10,000,000, and of exports only a little less. By far the most important export is tin; the next being spices, sugar, and tobacco. Georgetown, the capital, is situated at the north-east extremity of the island, and is defended by forts; pop. about 25,000. Province Wellesley, on the peninsula opposite, forms part of this same settlement administratively. Pop. of Penang, including Province Wellesley and the Dindings, (1881) 190,597; (1891) 235,618, one-half Chinese, nearly one-fourth Malays, and one-sixth Tamils and others from India. Nearly two-thirds of the total are males. Many thousands of Chinese and Indians arrive every year, and the arrivals (129,896 Chinese and 20,599 Indians in 1887) are not balanced by the departures. Province Wellesley, 45 miles in length by 4 to 11 in breadth, with an area of 270 sq. m., produces tapioca, sugar, rice, and cocoa-nuts. Another dependency of the settlement is the Dindings, including the island of Pangkor, situated about 80 miles S. of Penang. Pop. 2322. The native raja of Kedah ceded Penang to the English in 1785 in return for an annual pension of £1000. Thirteen years later the same power acquired what is now Province Wellesley, for the purpose of putting down piracy. In 1805 the East India Company, the proprietors of the settlement, made Penang a presidency of equal rank with Bombay and Madras. From 1826 Singapore and Malacca were united with it, but in 1831 the seat of government was transferred from Penang to Singapore.

PENANG LAWYERS is the commercial name for the stems of a species of palm imported from Penang for walking-sticks. They are small and hard, and have a portion of the root-stock attached, which is left to form the handle.

Penarth Beds. See TRIASSIC SYSTEM.

Penates. See LARES.

Pencils. A slender stick of black lead, slate, or coloured chalk, encased in a small round piece of wood, is called a pencil; but the term is also applied to small hair-brushes used by artists, and it was to these that the name was originally given. Some early manuscripts have lines upon them ruled with ordinary metallic lead. When pencils of Black Lead (q.v.), called also graphite and plumbago, were first used is uncertain, but Beckmann points out that they are distinctly mentioned in a book on fossils by Conrad Gesner, printed at Zurich in 1565. The discovery of the use of black lead as a material for writing or drawing with was an important one, since for work where words or lines may require to be frequently rubbed out no other substance has such valuable properties.

For a long time the plumbago from the Borrowdale mines in Cumberland furnished the 'leads' for the best pencils ever made. These mines have been exhausted since 1850; but when the

graphite from them was available it had, in the case of the larger and purer pieces, only to be cut into square rods of the proper size for pencils. In order to work up the smaller bits, cuttings, and dust of this precious material, Mr W. Brockedon, in 1843, patented a method by which he first reduced these small pieces to powder, and then, by subjecting it to great pressure in dies from which air is exhausted, produced a cake as solid and compact as the natural graphite, and equally suitable for cutting into leads. For a considerable number of years past, owing to the Borrowdale plumbago being worked out, black-lead pencils, as well as coloured pencils or crayons, have been made by the process invented about the close of the 18th century by Conté of Paris, which consists in thoroughly mixing the black lead with clay, both being first reduced to a state of fine division and most carefully purified. The proportions of graphite and clay vary from two of the latter to one of the former (for light hard pencils) to equal parts of the two ingredients (for the dark soft kinds). Water is added to the mixture, which is repeatedly ground, and then placed in canvas bags and squeezed in a hydraulic or steam press till it acquires the consistency of stiff dough. In this state it is placed in a strong metal cylinder, whose bottom is perforated with apertures of the proper size for the section of the pencil leads. The black-lead mixture, being in a plastic state, is then squeezed out through the apertures by a plunger into continuous strips or threads, which are arranged in straight lengths on a board to dry. After being exposed to a slight artificial heat, the strips are cut into the usual lengths for pencils, and placed in a covered crucible, which is raised to a red heat. When cooled they are ready for use.

An extensive mine of fine graphite was opened at Bogodolsk in eastern Siberia about 1850. Much of this black lead is scarcely if at all inferior in quality to that formerly obtained in Cumberland. Pencils have been made from this graphite in the unmixed state, and Faber of Nuremberg still makes fine pencils of it. These have the words 'Graphite de Siberic' stamped upon them. Dixon's American graphite pencils are made from the plumbago found at Ticonderoga on Lake George, but it is mixed with clay as above described. Workable deposits of graphite are found at several places in Canada. A good deal of what occurs in the township of Buckingham, in the province of Quebec, is almost pure, and is made into pencils. For other localities, see BLACK LEAD.

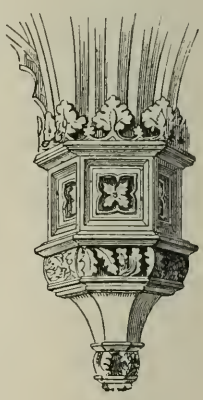
The wood used for pencils is invariably that of the Virginian or Florida cedar (see JUNIPER), which, being straight grained and easily cut, is remarkably well suited for the purpose. Two rectangular pieces of the proper size, cut out by machinery, go to make a pencil, the one containing the groove for the lead being thicker than the other. After the lead is inserted the two pieces are glued together, and then cut to a round shape by revolving cutters. The operations of cutting out the square fillets of wood and rounding them after they are glued are very rapidly performed. Pencils are sometimes cut in a hexagonal shape. Besides the maker's name, letters indicating the character of the lead are stamped upon pencils. For Great Britain these are H, HH, HHH, B, BB, BBB, HB, and F. H signifies hard; once and twice repeated it means harder and very hard. B stands for black (and soft), and, when repeated, for still blacker. HB, the most generally useful, means hard and black; while F signifies firm. In the United States the letters used differ somewhat. They are H, hard; VH, very hard; VVH, still harder; S, soft; VS, very soft; VVS, still softer, for deep black shading; M, medium; MH, medium hard; MB, medium black.

Owing to the multiplicity of processes for reproducing pen-and-ink drawings (see ILLUSTRATION), and the cultivation of that method for book illustration, the black-lead pencil is much less used now than in the earlier half of the 19th century. Drawings in chalk or charcoal, since either material makes a much blacker line, have usually deeper and more effective shading than can be given with pencil. Still, a finished drawing in black lead by a skilled hand has charms of its own, and it is to be regretted that so few of these of any importance are now made by artists of high standing.

Coloured pencils are made with ordinary pigments—e.g. Prussian blue and chrome yellow for their respective colours—mixed with white wax and tallow or with gum and tallow, clay being sometimes added; but none of these coloured preparations are heated like those made of graphite and clay. Copying and ink pencils are made of a concentrated solution of an aniline violet added to a mixture of graphite and China clay. For some kinds gum is added, and in such cases graphite is sometimes omitted.

The arrangement of a small rod of black lead, which is kept projecting as it wears away from a tube fitted to a metal pencil-case, and which has since been so much used, was patented by Hawkins and Mordan in 1822. An alloy of lead, antimony, and a little mercury is made into ever-pointed pencils for writing on paper prepared with a suitable surface.

The manufacture of black-lead and coloured pencils is carried on most extensively at Nuremberg, where there are more than a score of factories, employing in all nearly 6000 hands, and producing annually some 250 million pencils, worth about £420,000. Faber founded a branch in New York in 1861. Four years later the Eagle and American Pencil Companies were established, and the other surviving firm, the Dixon Crucible Company, in 1872.



Pendant.

Pendant, a hanging ornament, used in ceilings, vaults, staircases, timber-roofs, &c. It is sometimes a simple ball and sometimes elaborately ornamented, and is chiefly used in the later Gothic and Elizabethan styles.

Pendant. See FLAG.

Pendennis Castle. See FALMOUTH.

Pendle Hill. See CLITHEROE.

Pendleton, a north-western suburb of Manchester, wholly within the borough of Salford. Pop. 40,246.

Pendragon. See DRAGON.

Pendulum. The two chief varieties are the *simple* pendulum and the ordinary or *complex* pendulum. Examples of the latter occur in all the forms of clockwork where a balance-wheel has been dispensed with (see HOROLOGY). A small leaden or golden bullet, when suspended from a fixed point by an extremely fine thread, may represent a simple pendulum, provided it vibrates in a small circular arc. Once set in motion, this instrument will move in the same arc for ever unless interfered with, because at each swing, when descending through the first half of

its circular path, it acquires energy enough to raise it to an equal height on the opposite side. In ordinary experiments the bullet will perform many thousand oscillations by itself alone, before the resistance of the air and other interferences cause the movement to subside and at last cease, by imperceptibly diminishing the length of the arc.

This long-continued and self-sustaining action is manifestly due to the attraction of the earth, the force that causes a stone to fall to the ground, because at the end of each swing of the bullet its weight tends to pull it vertically downwards, and the string constrains it to repeat its course along the circular arc. A most interesting and valuable application of the pendulum, therefore, is for measuring the acceleration of velocities of falling bodies. For that purpose it is much superior to Atwood's Machine (q.v.) or any other method which has yet been devised.

If the circular path or swing is short—not exceeding, for example, that of a clock pendulum which beats seconds—there are two results to be remembered. First, that so long as the length of thread is unchanged, it matters not how far the bullet may swing on each side, the time or duration of each oscillation is also unchanged. This 'pendulum-law' was discovered by Galileo in the church of Pisa, as he watched a lamp swinging by a chain. The quality that each swing occupies the same time is so important in horology that the introduction of the pendulum by Huygens as a time-measurer formed the principal epoch in the history of that science. The term *isochronism* ('equal-timeness') was invented to mark this property of the pendulum. The second law of the pendulum is that to make the bullet move faster we must shorten the thread in the following proportion: for twice as many oscillations take a quarter the length of string; for thrice as many take one-ninth the length; for four times as many take one-sixteenth the length. That law is otherwise expressed by saying the length of the thread is inversely as the square of the number of oscillations made in a given time (see CENTRE OF OSCILLATION).

These and other properties of the pendulum are wrapped up in the formula: $t^2 : \pi^2 :: l : g$, which mathematicians have established: where t = time in seconds of one oscillation, l = length (in inches) of the thread, $\pi = 3{\cdot}1415927$, a well-known ratio; and g = the accelerating force of gravity, or twice the space through which a heavy body falls in one second. When $t = 1$ in that formula —i.e. when our pendulum beats seconds, a result easily attained at any part of the world—then immediately we have $g = \pi^2 l = 9{\cdot}8696l$. In other words, multiply the length of the seconds pendulum in any latitude or longitude by the fixed number 9·8696 to find the value of g. By this valuable and simple result it has been shown that the force of gravity slightly and gradually increases as we travel from the equator towards either pole, the length of the seconds pendulum diminishing in the same proportion. The poles are therefore nearer to the centre than the equator is, which is an independent proof that our planet is spheroidal, and resembles in shape an orange rather than a lemon.

The following table readily gives the length of the seconds pendulum at any of the stations by dividing the corresponding number in the third column by the fixed number 9·8696. At London, for example, 32·191 ÷ 9·8696 = 3·262 feet, length of seconds pendulum. Dent's clock in the tower of the House of Commons beats once in two seconds, and must therefore have a pendulum 13·046 feet long.

The table also shows the acceleration (feet per second) due to gravity, as ascertained from observations made by means of the seconds pendulum. The results are arranged in the order of their latitude.

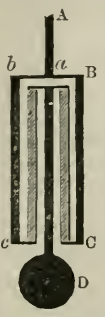
Since the length of the seconds pendulum is due entirely to natural causes, and can always be easily verified, it was chosen as a standard of the British measures of length. Experience has taught, however, that these are more easily known by preserving an artificial standard.

The universal application of the pendulum for time-measurement and ascertaining the local value of g has been followed by some special uses of it which are of interest. Thus, Sir G. B. Airy, the late astronomer-royal, applied it to form an estimate of the earth's mean density by observations taken at a coal-pit, 1200 feet deep, near South Shields. One pendulum being stationed at the surface and another at the bottom of the pit, their oscillations were exactly compared by means of an electric wire, with the result that a clock at the mouth of the pit would gain 2¼ seconds per day if removed to the bottom. From these data (*Phil. Trans.* 1856, p. 297) the density of the earth was estimated to be 6·565.

By the Foucault experiment the pendulum was utilised in a striking manner to prove the perpetual rotation of our planet round its axis. A globe of metal is suspended by a long wire to a lofty roof, the point of suspension being vertically over the centre of a round table; and after being drawn aside from the position of rest this pendulum is allowed to begin its vibrations, but so as to have no tendency to right or left. Students of dynamics know that it must continue swinging to and fro in the *same plane* unless interfered with from without. Owing to that the table beneath the pendulum, when carefully observed, is seen to revolve very slowly in a direction contrary to the hands of a watch; but since the floor and whole building revolve with the table, the observers naturally refer the relative motion to the pendulum, still swinging in its original plane. By marking twenty-four equal divisions round the edge of the table the spectators would be furnished with a good clock, the pendulum pointing out the hour at the point where it first began its oscillations, and apparently revolving in the usual direction.

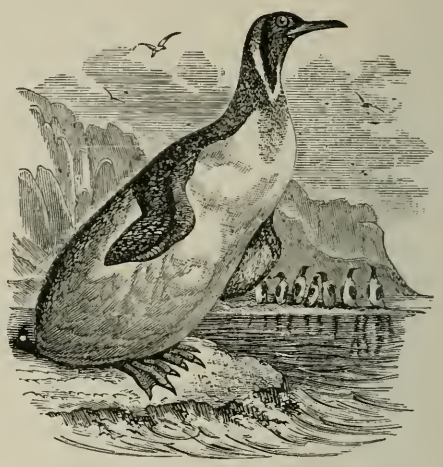
The pendulum, in Horology, is absolutely accurate as a time-keeper, if only the proper length is preserved. That is mainly done by means of a screw turning on the rod, under the 'bob' or ball, so as to push it up and therefore shorten the pendulum, or let it fall lower down and lengthen the pendulum. It was found in winter that clocks went too fast, and at midsummer too slow, because cold shortened the metallic rod and heat lengthened it. A further refinement was therefore devised to secure a uniform length without the screw adjustment, the result being what are known as 'compensation pendulums.' Both the common methods of these depend on the same principle. (A simple and practically accurate form of pendulum is made with a wooden rod, which is less liable to expansion

and contraction than metal.) The 'mercurial pendulum' carries within it a glass cylinder nearly full of mercury, so proportioned in quantity to the weight of the pendulum that when the latter expands downwards by the heat the change is counterbalanced by the upward expansion of the liquid in its jar. In winter, of course, the pendulum and the quicksilver are similarly contracted in opposite directions, to secure a good average length and mark better time. The second form of compensation pendulum is called the 'gridiron,' because it consists of several upright bars, as in the diagram. If the black bars be, for example, steel, and those between be brass or copper, then by a proper adjustment of their lengths any change of temperature will not materially affect the time-keeping property of the pendulum. Brass is much more subject to extension and contraction than steel. It is obvious from the figure that when the heat dilates the brass bars they must raise the bob D, and therefore counteract the downward extension of the steel bars, such as BC or *bc* and A*a*. For accurate and uniform time-measurement the gridiron has, in the experience of some astronomers, proved superior to the mercurial pendulum.



Penelope, in Homeric legend, the wife of Ulysses (Odysseus), and mother of Telemachus, who was still an infant when Ulysses went to the Trojan war. During his long wanderings after the fall of Troy he was generally regarded as dead, and Penelope was vexed by the urgent wooing of many suitors, whom she put off on the pretext that she must first weave a shroud for Laertes, her aged father-in-law. To protract the time she undid by night the portion of the web which she had woven by day. When the suitors had discovered this device her position became more difficult than before; but fortunately Ulysses returned in time to rescue his chaste spouse from their distasteful importunities. Later tradition represents Penelope in a very different light, asserting that by Hermes (Mercury), or by all her suitors together, she became the mother of Pan (q.v.), and that Ulysses, on his return, divorced her.

Penguin. This name is applied to a group of birds containing three genera, Spheniscus, Endyptes, and Aptenodytes—the largest species, the 'Emperor' (*A. forsteri*, 50 inches in height) and 'King' (*A. pennantii*) penguins, belonging to the latter genus. The most remarkable peculiarity of these birds is the flattened wing, which is clad with flat scale-like feathers; the whole limb, unfit for flight, is admirably suited for swimming. The feathers of the penguin—instead of being disposed in feather-tracts, separated by intervals (*apteria*) upon which no feathers grow, as is the case with all other birds, not excepting even the ostrich and cassowary—form a continuous covering to the body. These peculiarities, coupled with some others in internal structure, mark off the penguins as a very distinct group of birds. By some they are placed in the same group with the auks, or put in a special group (*Impennes*) by themselves. The penguins are entirely confined to the Antarctic and to the south temperate regions (Patagonia, Cape Colony, Australia, New Zealand), and are aquatic in their habits, as is shown by the webbed feet as well as by the remarkable modification of the wings already referred to. In some situations they are extremely abundant, and make their nests in a common area; the nest is nothing more than a hole in the sand in which the female deposits a single egg. The stupidity of these birds is perhaps due to the inaccessibility of the rocks and shores where so great a number live and breed: having been comparatively little interfered with by man, they show no terror at the sight of him. When intruders invade their breeding-places they can and do, however, inflict severe wounds with their sharp bills. The plumage of the neck is valued by furriers for collars and tippets; and large numbers of 'Johnnies,' as the sailors call them, are slaughtered annually. The flesh though dark is wholesome food, and makes excellent 'hare-soup;' the belly is loaded with fat. That the penguins are not altogether a modern race of birds is shown by the remains of a species—*Palæeudyptes antarcticus*—which existed in New Zealand in late Eocene or early Miocene times. This bird differed from existing penguins in having rather longer wings, and may therefore conceivably have possessed the power of flight; it was a large form like the King Penguin of to-day.



King Penguin (*Aptenodytes pennantii*).

Penicillaria. See GUINEA CORN, and MILLET.

Penicuik, a town of Edinburghshire, on the left bank of the North Esk, 10 miles S. of Edinburgh by road, but 16 by a branch line (1872). It has a Romanesque church-tower and large paper-mills, dating from 1709; whilst 2 miles NNE. are Glencorse barracks (1804–82), originally a depôt for French prisoners. Pop. (1841) 907; (1891) 3562. See Wilson's *Annals of Penicuik* (Edin. 1891).

Peninsular and Oriental Company carry mails and passengers between Great Britain and India, China, and Australia. The company in its present form was incorporated by royal charter in 1840, although it had then had an existence of three years' duration as the Peninsular Company, which carried mails to Portugal and the south of Spain, and afterwards to Egypt. The 'P. & O.' own a fleet of about sixty vessels, of an average size of 5000 tons each. They carry mails from Brindisi to Bombay, weekly, in the contracted time of 12½ days; from Brindisi to Shanghai, fortnightly, in 31 days; and from Brindisi to Adelaide, fortnightly, in 28½ days. The company also maintains a three-weekly service between Venice, Brindisi, and Egypt, and in Asia has lines from Bombay to Colombo, thence to Calcutta, and to Singapore, Hong-kong, Shanghai, and Japanese ports. See the company's *Pocket-book* and *Monthly Handbook;* and for information on other great shipping lines, see the article SHIPBUILDING in this work, and works there cited.

Peninsular War (1807–14). The dissensions between Charles IV., king of Spain, and his son Ferdinand gave the Emperor Napoleon I. an opportunity of interfering in the affairs of that country. In pursuance of a treaty ratified on 29th October 1807 with the Spanish king, he had sent an army into Portugal under Junot, by whom Lisbon was seized, and the members of the royal house of Braganza obliged to flee to the Brazils. Ostensibly with the object of supporting Junot's army, other French troops gradually occupied Salamanca, Valladolid, and other important positions in Spain, including Madrid, where Murat was in command. A popular outbreak against the king and his favourite, Manuel Godoy, caused the former to abdicate and his son Ferdinand to assume the crown. But the latter was induced to meet the French emperor at Bayonne, and by him held a prisoner, while his father was again proclaimed king. Riots at Madrid, Toledo, and other places during the spring of 1808 caused the feeble king such alarm that he surrendered his crown to Napoleon, by whom it was bestowed upon his brother Joseph Bonaparte, then king of Naples. He was proclaimed in Madrid on 24th July 1808.

Owing to the large powers of the local junta, and to a decentralised form of government, the action of the capital of Spain had little effect upon that of her provinces, which rose against the French and those who favoured them in all directions. The organised forces of Spain amounted at this time to about 127,000 of all arms, while the French army in the Peninsula, exclusive of Junot's troops in Portugal, consisted of some 80,000 conscripts of various nations, French, Swiss, Italians, Poles, and even Portuguese, soon reinforced by 23,000 fresh troops. Arms, clothing, and money were freely supplied by Great Britain to the patriots of Spain and Portugal, whose numbers rapidly increased. The first operations of the French under Marshal Bessières in the north were uniformly successful, except at Saragossa, which Palafox gallantly held against Lefebvre-Desnouettes. In Catalonia they suffered several defeats, and in Andalusia their general, Dupont, surrendered at Baylen with 18,000 men. The first armed interference of the British in the affairs of the Peninsula was the despatch on 12th July 1808 of Sir Arthur Wellesley with some 30,000 men to Portugal. Landing these troops in Mondego River, he defeated Laborde at Roriça and Junot at Vimiera, but then handed over the command to Sir Harry Burrard, who had been sent out to supersede him, to be himself superseded within a few hours by Sir Hew Dalrymple. The latter officer concluded the convention of Cintra with the French commander, who evacuated Portugal by 30th September 1808. The three English generals were examined before a court of inquiry as to this convention, but no further steps were taken.

Sir John Moore, appointed to the command of the British troops (some 30,000) in Portugal on 6th October, had moved to Valladolid by 22d December, effecting a junction with Sir David Baird's division from Coruña. But the Spanish troops had in the meantime suffered a succession of defeats. The French had received large reinforcements; Napoleon himself was in Madrid; and Soult with 60,000 men was in his front. Moore therefore executed a rapid and masterly retreat to Coruña, and there fought a successful battle to cover the embarkation, being mortally wounded himself at the moment of victory. For three months no further steps were taken by the British government, but in December Sir John Cradock was sent out to take command in Portugal, and he took up a position covering Lisbon from the French, now under Marshal Victor. In this position Sir Arthur Wellesley, who was again sent out, found matters on 22d April 1809. The French armies in Spain now numbered nearly 400,000 men, divided into eight corps d'armée, under six marshals and Generals Junot and St Cyr, and operating in the north, south, east, and west. So long as Napoleon himself was able to direct operations they were characterised by unity of purpose and consequent success. Saragossa, attacked for the third time, after a memorable defence of sixty-three days, surrendered to Marshal Lannes on 21st February 1809, and many victories were gained over the Spanish levies; but in Catalonia St Cyr effected comparatively little. The outbreak of war in Germany drew Napoleon to that country in April, and the operations in Spain were somewhat neglected in consequence. The jealousies of the French commanders too prevented any unity of action there.

Sir A. Wellesley first marched against Soult with 20,000 British and 40,000 Spanish under Cuesta, and drove him out of Portugal. King Joseph, with 80,000 men under Marshal Victor, attacked at Talavera on 26th July and suffered a severe defeat. For this victory Sir A. Wellesley was created Viscount Wellington, but, being left without reinforcements, he was obliged to retire to Almeida, while the defeat of the Spanish at Ocana (November 20) enabled the French to overrun the whole of Andalusia, except Cadiz, which still held out. Wellington, foreseeing the impossibility of taking the offensive at that time, prepared during the winter a triple line of earthworks, 29 miles long, from Torres Vedras on the Zizandra to Alhandra on the Tagus, thus covering his base at Lisbon. The French, 65,000 strong, under Masséna, moved against him in the spring of 1810, captured the fortress of Ciudad Rodrigo on the 11th July, and attacked him in the position of Busaco on 29th September. The attack was beaten off, and Wellington, carrying out his preconceived plan, retired slowly into the lines of Torres Vedras, carrying with him as much of the resources of the country as possible, and directing the Portuguese troops to harass the flanks and rear of the French. To avoid starvation Masséna, finding himself unable to attack Wellington's fortifications, and having lost 30,000 men, began to retire on 14th November. Reinforcements having reached Wellington early in 1811, he followed, defeated Masséna at Sabagal on 3d April 1811, and drove him out of Portugal. Soult in the meantime had defeated the Spaniards at Gebora (February 19), and captured the fortress of Badajoz. He also invested Cadiz, but General Graham with a force of 12,000 men attacked and defeated Marshal Victor's covering force at Barrosa on 5th March, which checked his further movements. Wellington, now designing to march on Madrid and thence against the French line of communications with Bayonne, found it necessary to capture Badajoz and Almeida. Masséna, at the head of 50,000 men, marched to the relief of the latter place. He was checked at Fuentes de Oñoro on 5th May, where a hard-fought battle caused him to retreat and abandon Almeida to the British. Wellington then turned towards Badajoz, which Soult endeavoured to relieve with a force of 23,000 men. The British (7000) and Spaniards (25,000) engaged him on the 16th May in the bloody battle of Albuera, compelling him to retire, which he did in a southerly direction.

Matters were, however, in a very critical state for the British, for the whole of Valencia, Asturias, and Galicia was in the hands of the French, who still had nearly 300,000 men in Spain, and had received no other check except from General Hill in Estremadura and at Tarifa, which fortress repelled Soult. Napoleon, too, threatened to take the field again in person. But this was prevented

by the outbreak of war between France and Russia, and early in 1812 Wellington commenced his well-matured plan for freeing Spain from the invader. He captured Ciudad Rodrigo on 19th January, stormed Badajoz on 6th April, and called in Hill's division from the south. Marmont, who had collected his troops about Salamanca, found his flank threatened, and had at first to retire; but on 22d July he turned upon the British, and fought the battle of Tormes, where he was wounded and his army defeated. Wellington entered Madrid on 12th August. King Joseph then withdrew Soult from Andalusia to Valencia, where they joined Suchet. But the Spanish army neglected to guard the British line of communications, and Clausel, who succeeded Marmont, proved so formidable a general that Wellington again found himself obliged to retire towards Salamanca and Portugal.

Events elsewhere, however, lessened the power of his enemies, reducing their numbers to 197,000 men. Jealousy existed between Joseph and his generals; and Wellington's position was strengthened by his appointment as commander-in-chief of the Spanish and Portuguese armies. These now amounted to 200,000 men, of which 70,000 Anglo-Portuguese had been brought into a good state of discipline. He again advanced eastward in the spring of 1813, obliging the French to evacuate Burgos and the line of the Ebro. They attempted to withstand him at Vittoria on 21st June, but sustained a crushing defeat, abandoning all their artillery, stores, and baggage. The blockades of Pampeluna and St Sebastian followed. Joseph, who had quarrelled with Soult, was superseded in the command, which was given to the latter. In spite, however, of great skill on his part, a series of terrible battles in the Pyrenees were uniformly disastrous to him. St Sebastian was taken on 7th October, the victory of Nivelle won on 10th November, and Wellington enabled to base himself on the northern ports. In February 1814 Bayonne was invested, on 27th Soult was defeated at Orthes, and again at Toulouse on 10th April, which city was occupied by the British. But Napoleon had already abdicated, having, after the disastrous Russian campaign, been overpowered by the allied forces of Russia, Prussia, and Austria, by whom France was invaded and Paris taken. See also articles on France, Spain, Portugal, Wellington, Napoleon, Soult, Masséna, Sir John Moore, Vittoria, Badajoz, Torres Vedras, Coruña, Busaco, &c.; and Sir W. Napier's *History of the Peninsular War* (6 vols. 1828–40).

Penitential Psalms, seven of the Psalms of David, so called as being specially expressive of sorrow for sin, and accepted by Christian devotion as forms of prayer suitable for the repentant sinner. They are Psalms vi., xxxii., xxxviii., li., cii., cxxx., and cxliii. according to the Authorised Version, which correspond with vi., xxxi., xxxvii., l., ci., cxxix., and cxlii. of the Vulgate. These Psalms have been set apart from a very early period, and are referred to as such by Origen. Pope Innocent III. ordered that they should be recited in Lent. They have a special place in the Roman Breviary, and more than one of the popes attached an indulgence to the recital of them. The most deeply penitential, and the most frequent in use, both public and private, is the 51st Psalm, or the *Miserere* (50th in the Vulgate).

Penitentiary, the name given to one of the offices of the Papal court, and also to the dignitary (a cardinal, called *Penitentiarius*) who presides over it. The subjects which come under the notice of the penitentiary are all matters relating to the confessional, especially the absolution from sins and from canonical censures, reserved to the pope, and in certain cases dispensations from the impediments of marriage. See Prisons.

Penkridge, a town of Staffordshire, on the Penk, 6 miles S. of Stafford by rail, in an agricultural district. Pop. 3134.

Penmaenmawr, a watering-place of Carnarvonshire, 4 miles SW. of Conway by rail. The mountain of Penmaenmawr, the northern extremity of the Snowdon group, is 1553 feet high; on its summit are the remains of a great British fort, Dinas Penmaen.

Penn, William, the founder of the colony of Pennsylvania, was the son of Admiral William Penn, and was born at London, 14th October 1644. His early years were spent partly in Essex and partly in Ireland, where his father had several estates, the gift of Cromwell. Penn studied at Christ Church, Oxford, and while there was converted to Quakerism by the preaching of a disciple of George Fox, named Thomas Loe. His enthusiasm for his new faith assumed a pugnacious form. Not only did he object personally to attend the services of the Church of England, and to wear the surplice of a student—both of which he considered eminently papistical—but, along with some companions who had also become Quakers, he attacked several of his fellow-students, and tore the obnoxious robes from their backs. For this unseemly procedure Penn was expelled from the university. His father was so excessively annoyed at his conduct that he gave him a thrashing, and turned him out of doors; but he soon afterwards relented, and sent his son to travel on the Continent, in the hope that change of scene and the gaiety of French life would alter the bent of his mind. They failed, however, to effect this, but the youth certainly acquired a grace and suavity of address that he did not before possess. In 1666 the admiral sent him to Ireland to look after his estates in the county of Cork, which Penn did to his father's complete satisfaction; for in matters of business he was as practical an Englishman as in religion he was an out-and-out mystic. In the city of Cork, however, he again fell in with Thomas Loe, and for attending a Quaker meeting was, along with others, imprisoned by the mayor, but was immediately afterwards released on appealing to the lord president of the Council of Munster, who was personally acquainted with him. On his return to England, Penn and his father again quarrelled, because the 'conscience' of the former would not allow him to take off his hat to anybody—not even to the king, the Duke of York, or the admiral himself. Penn was again turned out of doors by his perhaps testy, but assuredly provoked parent. The mother, however, stepped in, and smoothed matters so far that Penn was allowed to return home, and the admiral even exerted his influence with the government to wink at his son's attendance at the illegal conventicles of the Quakers, which nothing would induce him to give up. In 1668, however, he was thrown into the Tower, on account of a publication entitled *The Sandy Foundation Shaken*, in which he attacked the ordinary doctrines of the Trinity, God's 'satisfaction' in the death of Christ, and justification by the imputation of Christ's righteousness. While in prison he wrote the most famous and popular of his books, *No Cross, no Crown*, and *Innocency with her Open Face*, a vindication of himself that contributed to his liberation, which was obtained through the interference of the Duke of York. In September 1670 Admiral Penn died, leaving his son an estate of £1500 a year, together with claims upon government for £16,000. In 1671 the upright but incorrigible sectary was again committed to the Tower for preaching; the Conventicle Act did not touch the case, but, as he refused to

take the oath of allegiance, he was sent to Newgate for six months. Here he wrote four treatises; one of them, entitled *The Great Cause of Liberty of Conscience*, is an admirable defence of the doctrine of toleration. After regaining his liberty he visited Holland and Germany for the advancement of Quakerism. The Princess-Palatine Elizabeth, the granddaughter of James I., showed him particular favour. On his return he married, in the beginning of 1672, Gulielma Maria Springett, daughter of Sir William Springett, and for some years thereafter continued to propagate, by preaching and writing, the doctrines of his sect.

Circumstances having turned his attention to the New World, he in 1681 obtained from the crown, in lieu of his monetary claim upon it, a grant of territory in North America. Penn wanted to call it Sylvania, on account of its forests, but the king (Charles II.) insisted on the prefix Penn in honour of his father. His great desire was to establish a home for his co-religionists in the distant West, where they might preach and practise their convictions in unmolested peace. Penn, with several friends, sailed for the Delaware in September 1682, was well received by the settlers, and in October held his famous interview with the Indian tribes, under a large elm-tree at Shackamaxon, afterwards Kensington, and now a part of Philadelphia. He planned and named the city of Philadelphia, and for two years governed the colony wisely and well, but on strictly Puritan principles. Not only Quakers, but persecuted members of other religious sects sought refuge in his new colony, where from the first the principle of toleration was established by law.

Towards the end of the reign of Charles II. Penn returned to England to exert himself in favour of his persecuted brethren at home. His influence with James II.—an old friend of his father's—was so great that many people have never felt quite satisfied about the nature of their relations. The suspicion, however, that Penn allowed himself to be used as a tool by the court is not justified by any known facts, and Macaulay—who with an ungracious animosity has urged the view of his complicity in some of the disgraceful incidents that followed Monmouth's rebellion—has been convicted of haste and inaccuracy in several important particulars. At anyrate, his exertions in favour of the Quakers were so far successful that in 1686 a proclamation was issued to release all persons imprisoned on account of their religious opinions, and more than 1200 Quakers were set free. In the April following James issued an edict for the repeal of all religious tests and penalties, but the mass of Nonconformists mistrusted his sincerity, and refused to avail themselves of it. After the accession of the Prince of Orange as William III. Penn was twice accused of treason, and of corresponding with the exiled monarch, but was acquitted. In 1690 he was charged with conspiracy, but was not arrested. Nevertheless, in the following year, the charge was renewed. Nothing appears to have been done for some time, but Penn at last, through the kindly offices of his friends, Locke, Tillotson, and others, had the matter thoroughly investigated, and he was finally and honourably acquitted in 1693. In 1692 he had been deprived of his government, but it was restored to him in 1694. In the latter year his wife died, and Penn published a memoir testifying to her great virtues; but in less than two years he married again, his second wife being Hannah Callowhill, of Bristol, a Quaker lady. In 1699 he paid a second visit to the New World, where Pennsylvania required his presence to restore peace and order after the arbitrary behaviour of his deputy. His stay, which lasted two years, was marked by many useful measures, and by efforts to ameliorate the condition of both the Indians and Negroes. He departed for England towards the end of 1701, leaving the management of his affairs to an agent named Ford, whose villainy virtually ruined Penn. When the rogue died he left false claims against his master, which Penn refused to pay, allowing himself to be thrown into the Fleet in 1708. His friends afterwards procured his release, but not till his constitution was fatally impaired; for the last five years of his life his memory and understanding were greatly weakened. He died at Ruscombe, in Berkshire, July 30, 1718. The proprietary claims of his descendants were bought up by a pension of £4000, which in 1884 was commuted (see PENSIONS).

See Macaulay's *History of England*, and J. Paget's *Inquiry into the Evidence of the Charges brought by Lord Macaulay against William Penn* (1858); the Life prefixed to his collected works (2 vols. 1726), and to later issues of 'select works;' and Lives by Clarkson (1849), Hepworth Dixon (new ed. 1856), Robert J. Burdette (New York, 1882), and Stoughton (new ed. 1883).

Pennalism. See FAGGING.

Pen-names. See PSEUDONYMS.

Pennant, THOMAS, traveller, was born of a good old Welsh family at Downing, near Holywell, Flintshire, 14th June 1726, and was educated at Wrexham, Fulham, and Hadley. In 1744 he went up to Queen's College, Oxford, but he left without taking a degree, having meanwhile, in 1746, ridden down into Cornwall—the first of his many tours. These included visits to Ireland (1754); the Continent (1765), where he made the acquaintance of Buffon and Voltaire; Scotland (1769 and 1772), which 'was then,' he says, 'almost as unknown as Kamchatka, but ever since has been *inondée* with southern visitants;' and the Isle of Man (1774), besides rambles through England and his native principality. He married twice, in 1759 and 1777; was made member of the Royal Society of Upsala, an F.R.S., and a D.C.L. of Oxford; and died at Downing, 16th December 1798.

From boyhood a naturalist, for years a correspondent of Linnæus, Pennant published *British Zoology* (1765–77), *British Quadrupeds* (1771), *Arctic Zoology* (1785), *History of London* (1790), &c.; but to-day he is chiefly remembered by his *Tours* in Scotland (3 vols. 1771–75) and Wales (2 vols. 1778–81), the former of which works extorted from Johnson the admission: 'He's a *Whig*, sir, a *sad dog;* but he's the best traveller I ever read; he observes more things than any one else does.'

See the amusing *Literary Life of the late Thomas Pennant, Esq., by Himself* (1793), and the memoir prefixed to Professor Rhys's edition of the *Tours in Wales* (3 vols. Carnarvon, 1883).

Pennat'ula, an interesting animal whose quill or feather-like appearance is suggested by the title and by the popular name Sea-pen. It is one of the Alcyonarian Actinozoa, in the same sub-class as Dead-men's Fingers, Red Coral, Gorgonia, &c. One species (*P. phosphorea*) is not uncommon at moderate depths (e.g. 20 fathoms) round British coasts. It consists of a basal stalk, by which the animal is probably fixed upright in the mud, and of a free axis bearing numerous polypes. The whole length is about 4–6 inches; the colour is

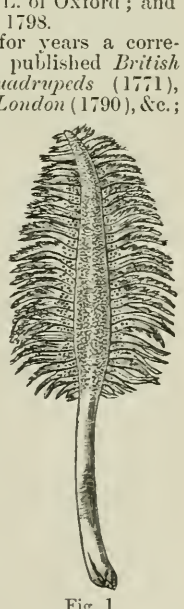


Fig. 1. Ventral View of *Pennatula phosphorea* (about one-half natural size).

deep red, and due to pigmented spicules of lime; the living animal is brightly phosphorescent. The stalk is really a tube, and can be somewhat inflated; the polypes are fused together in sets of a dozen or so up each side of the axis. These fused sets form a series of parallel leaves, somewhat like the barbs of a feather. The median part of the axis also bears rudimentary asexual polypes ('zooids') which are not fused. The whole axis is supported by a firmly-calcified internal stem.

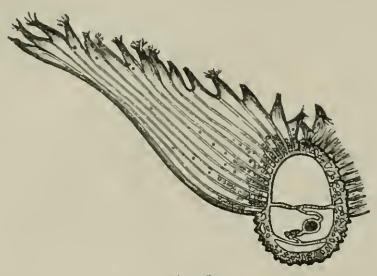

Fig. 2.
Cross section of the axis and one 'leaf' set of fused Polypes (after Marshall). The most ventral polype is longest and oldest.

The sexes are separate. Among related forms Virgularia, Funiculina, and Renilla are important. See *Report on Pennatulida*, by A. Milnes Marshall and W. P. Marshall (Birmingham, 1882).

Pennine Alps. See ALPS.

Pennine Range. See GREAT BRITAIN, Vol. V. p. 373.

Pennon, a small, pointed or swallow-tailed flag, borne by a mediæval knight on his lance. For pennant, as well as pennon, see FLAG.

Pennsylvania, since 1830 the second in population of the United States of America, is in shape a parallelogram, lying almost entirely between 42° and 39° 43′ 26″ N. lat. (Mason and Dixon's Line, q.v.), and between the irregular W-shaped Delaware River and 80° 31′ 36″ W. long. It is about 160 miles wide and 302 miles long from east to west; in area (45,215 sq. m.) it is the twenty-eighth state of the Union. In the north-western corner a triangular section extends to 42° 15′ N., forming part of the western boundary of New York, and giving Pennsylvania about 45 miles of coast on Lake Erie, with an excellent harbour at Erie.

Copyright 1891 in U.S. by J. B. Lippincott Company.

The Appalachian (q.v.) system of mountains crosses Pennsylvania from north-east to south-west. It here attains its greatest breadth, but none of the ridges reach any great altitude, though a few peaks among the Alleghanies attain a height of more than 2500 feet. Between the Blue or Kittatinny Mountains on the east and the higher Alleghany range on the west lie numerous minor forest-clad chains, interspersed with picturesque valleys, many of them rendered exceedingly fertile by the limestone bed which produces their soil. The surface of the state is naturally divided into three sections, the low district south-east of the mountains, the mountainous region, and the broken hilly plateau in the west. The triangular south-eastern part of the state consists of a narrow level plain near the Delaware River, with an elevation of not more than 100 feet above the sea, merging into a higher rolling region which extends to the base of the mountains. From Canada to the southern limit of the Appalachians extends an almost continuous valley, lying east of the main ranges, and separated from the coast region by the skirting south-eastern ridge. This 'great valley' is throughout its whole extent protected by a southern or eastern wall, except in Pennsylvania, where, through a break of about 50 miles, the Cumberland Valley is without a barrier toward the sea, and the fertile calcareous soil spreads out over Lancaster and parts of York, Berks, and Chester counties, making this one of the best farming regions of the country. The mountain region covers a belt which in places is more than 100 miles in width, and embraces about one-fourth of the area of the state. More than twenty ranges have been named, and the whole region is justly celebrated for its scenery. The rivers have in various places cut gaps through the ridges, thus affording passages for travel and commerce. Many of these water-gaps are exceedingly picturesque, and are much visited by tourists. The western plateau region comprises about one-half the area of the state; it is crossed by a few ridges, contains some isolated peaks, and is deeply furrowed by watercourses. Much of this section is heavily wooded.

The geology of Pennsylvania is particularly remarkable on account of the great development of the different periods of the Palæozoic era. The formations in the south-eastern part of the state are in dispute, but the vicinity of Philadelphia is generally admitted to be Archæan, and a little farther north is a belt of Quaternary alluvium. The Silurian deposits, which extend along the Hudson River in New York, continue into Pennsylvania and form the Kittatinny Mountains. The Devonian area of New York also covers a large part of the northern and north-eastern portion of Pennsylvania. West of the Kittatinnies the mountains present alternate Silurian and Devonian formations. West of the Alleghanies, throughout the great bituminous coalfields, the rocks are mainly conglomerate. The mountains and the western plateau region were originally highly elevated tracts, and have suffered to a vast extent from erosion. They have contributed nearly all the material for building up the lowland regions of New Jersey, Delaware, Maryland, and Virginia, and for the formation of the Lower Mississippi valley. The geological disturbances have been greatest and most frequent in the eastern part of the state, where the beds of anthracite coal occur at all angles and in some cases in a vertical position, whereas the bituminous coal-beds of the western field are nearly horizontal. The breaking of the strata and the enormous pressure to which the eastern coal-deposits have been subjected has resulted in giving Pennsylvania the most valuable anthracite basins of the country. It is a notable fact that the percentage of gas in the coal regularly increases from the eastern ranges to the western coal-measures. Although Pennsylvania is one of the richest mineral regions of the world, there is no department of her mineral wealth in which she exercises such exclusive control as in her deposits of anthracite coal. The bituminous coal is excellent in quality and variety, and the amount is practically inexhaustible, but the western coalfields are only part of a vast deposit which extends westward and southward into adjoining states. The iron ore which has contributed so materially to her wealth and prosperity is mined from an extensive belt which reaches on the north to Canada and on the south to Alabama. Even the petroleum and natural gas which are such important products of western Pennsylvania are found in other sections; but as yet her anthracite coal-basins are without a rival. The anthracite tract covers an area of 472 sq. m., and is situated in the highland district between the Delaware and Susquehanna rivers. The most important deposits lie in three great fields, known as the southern, middle, and

northern fields. It is estimated that with an output of 100,000,000 tons per year the anthracite mines would not be exhausted for two centuries. At present the production is about one-third of that estimate. Pittsburgh is the centre of the bituminous region, and the annual production is about 25,000,000 tons. The proximity of coal and iron in such vast quantities has made Pennsylvania a great mining and manufacturing state. Though equalled or surpassed by Michigan in the mining of iron ore, Pennsylvania still leads in the manufacture of pig-iron.

The successful boring for Petroleum (q.v.) in 1859 produced an excitement which was not surpassed even by the discovery of gold in California. Fortunes were made and lost in a day. The mining of petroleum and the manufacture of the various articles produced from it have created new and important industries. The utilisation of natural gas for heating and manufacturing purposes has also greatly modified methods of living in western Pennsylvania. Gold, silver, copper, and tin exist in Pennsylvania, but not in paying quantities, though copper is mined to a limited extent in Montgomery county. There are large zinc-works at South Bethlehem, and nickel is obtained in Lancaster county.

The eastern part of the state is drained by the Delaware and its tributaries the Schuylkill and Lehigh. The Susquehanna, with its affluents the North Branch, the West Branch, and the 'beautiful Juniata,' occupies the central drainage area. The Susquehanna is too rapid and too shallow for navigation, but it is used for floating quantities of timber, and coal, lumber, and other products are carried by the canals along its banks. A portion of the north-western region belongs to the valley of the Genesee, but the greater part of western Pennsylvania is drained by the Alleghany and Monongahela rivers, which, uniting at Pittsburgh to form the Ohio, furnish the state with a great highway of inland navigation. Pennsylvania has 8500 miles of railroad and 800 miles of canals. For the 'Pennsylvania system,' see PRISONS, p. 423.

In the mountains and wooded sections the smaller wild animals are still abundant. The panther, wild cat, and black bear are occasionally seen, and in some places the deer and wild turkey are not uncommon. The climate is healthful, but subject to extremes, and much modified by differences of elevation. Heavy snows fall on the mountains in winter, and the rivers of the western half of the state are often flooded in spring and summer (see e.g. JOHNSTOWN). Nearly one-fourth of the state is wooded; lumbering is one of the sources of wealth in the north, and farther south and west are great forests of hemlock, which maintain some of the largest tanneries in the world. In the Pocono swamps and plateaus, between the Wyoming and Kittatinny Mountains, the virgin growth of beech is known as the 'Shades of Death.' The soil, except in the mountains, is rich and fertile. Agriculture is a leading occupation, and in many crops Pennsylvania holds a high rank. The mountain regions and the western plateau are well suited for grazing, and the horses, cattle, sheep, and dairy products are noted for their excellence. The most important industries of Pennsylvania are mining and manufacturing. The amount of capital invested is greater than in any other state, and in the value of her manufactured products Pennsylvania is surpassed only by New York. Her commerce, both foreign and domestic, is very extensive. Shipbuilding is an interest of importance; river-steamers are built at Pittsburgh, and the perfection reached in the construction of iron steamships on the banks of the Delaware has given to that stream the title of the 'Clyde of America.'

History.—The first permanent settlement in the state was made in 1643 by Swedes, at the present site of Chester. Their colony of New Sweden was twelve years later conquered by the Dutch. In 1664 the English obtained possession, and the territory now called Pennsylvania was in 1681 granted by Charles II. to William Penn (q.v.). The friendly relations already existing between the whites and the Indians were re-established by Penn by a treaty, which was faithfully observed by both parties for more than fifty years. During the French and Indian wars, however, and again during the war of the revolution, the frontier settlements were attacked. In the struggle for independence and in the civil war Pennsylvania took a prominent part, and witnessed a number of the most famous battles and events connected with each. Schools were established by the earliest settlers, and a system of education formed part of the original scheme of government prepared by William Penn. The public schools now are attended by over a million pupils, and there are more than twenty universities and colleges in the state. A system of Soldiers' Orphan Schools was established in 1865, and there are numerous other charitable and educational institutions. There is a large foreign element in the population; many of the miners and ironworkers, especially, are of Irish, Hungarian, and Italian birth, and serious riots have not seldom occurred (see also MOLLY MAGUIRES). Among the farmers a very large proportion are of German descent, and still speak the *patois* known as 'Pennsylvania Dutch.' This belongs to the South German dialects, and is most closely related to the Pfälzisch; it preserves many old and curious German words, but is also interspersed more or less with Germanised English words, according to the locality. There are perhaps two million people around Philadelphia and New York who speak the *patois;* and in the country south-east of the Alleghanies they have their own dialectal newspapers. Specimens (spelt phonetically) of the dialect may be given: 'Ich trink tschenerli rooter wei' (I generally drink red wine); and ''s wetter iss d'r gants daak schee gwest' (the weather has been fine the entire day). See Prof. S. S. Haldeman's *Pennsylvania Dutch* (1872); also A. J. Ellis's *Early English Pronunciation* (part iv. 1875).

The state contains sixty-seven counties, and returns twenty-eight members to congress. Philadelphia, the metropolis of the state, is the leading manufacturing city of the Union and ranks third in population. Among other important cities, besides Pittsburgh and Alleghany, which form in all their interests a single community, are Harrisburg, the capital (pop. 1890, 40,221), Scranton (83,450), Reading (58,926), Erie (39,199), Wilkes Barre (37,651), Lancaster (32,090), Altoona (30,269), Williamsport (27,107), Allentown (25,183), York (20,849), Chester (20,167), &c. Pop. of the state (1800) 602,365; (1840) 1,724,033; (1880) 4,282,891; (1890) 5,258,014.

Penny (A.S. *pening* or *pending;* apparently from *pand*, 'a pawn,' Ger. *pfand*, Lat. *pannus*), a British coin, first mentioned in the laws of Ina, king of the West Saxons, about the close of the 7th century. It was at this time a silver coin, and weighed about 22½ troy grains, being thus about $\frac{1}{240}$th of the Saxon pound-weight. This relation to the pound-weight is evidently derived from the usage of the early Franks, who retained the Roman division of the *libra* into 20 *solidi*, and the *solidus* into 12 *denarii* (the denarius being thus the 240th part of the libra or pound). See MARK. Halfpence and farthings were not coined in England till the time of Edward I., but the practice previously prevailed of so deeply

indenting the penny with a cross mark that the coin could be easily broken into two or four parts as required. Silver farthings ceased to be coined under Edward VI., and silver halfpennies under the Commonwealth. Up to this time the penny had steadily decreased in weight; and under Elizabeth it was finally fixed at $7\frac{2}{3}\frac{3}{1}$ grains, or $\frac{1}{12}$ of an ounce of silver, a value to which the subsequent copper pennies closely approximated. In 1672 an authorised copper coinage of pence, halfpence, and farthings was established. In 1797 twopenny pieces were coined, but were soon withdrawn. The penny of the present bronze coinage, first issued in the end of 1860, is of only about half the value of the old copper penny and as metal is worth only about one-seventh of a penny. The German *pfennig* was also originally a silver coin, bearing the same relation to the German pound of silver as the English penny to its pound. Now the nickel ten-pfennig piece is the $\frac{1}{10}$th of the mark. The old Scots penny was only $\frac{1}{12}$th of the English one, as the pound Scots and the Scots shilling were also $\frac{1}{12}$th of the English coins of the same name. In the 12th century it was made very broad and thin.

Pennyroyal (*Mentha pulegium*), a species of Mint (q.v.), a native of Europe and western Asia, abundant in England and in some parts of Ireland, not found wild in Scotland, though sometimes grown there in gardens for its reputed medicinal qualities. It enjoys a high popular reputation as an emmenagogue, but no dependence may be placed in its efficacy. The name pennyroyal is given in North America to a small plant, *Hedeoma pulegioides*, allied to the mints, and having, like them, a pleasant aromatic smell and a warm pungent taste. It is much in use in domestic medicine, in the form of a warm infusion, to promote perspiration and as an emmenagogue.

Pennyroyal (*Mentha pulegium*).

Penny Weddings was the name given to festive marriage ceremonials in Scotland at which the invited guests made contributions in money (seldom more than 1s. each), to pay the general expenses, and leave over a small sum, which would assist the newly-married pair in furnishing their dwelling. This practice, now largely disused, was prevalent in the 17th century; and, as leading to 'profane minstrelsing and promiscuous dancing,' was denounced by an Act of the General Assembly, 1645, as well as by numerous acts of presbyteries and kirk-sessions about the same period.

Pennywort, a trailing herb (*Linaria cymbalaria*), with roundish reniform leaves, often cultivated in hanging-baskets. Marsh or Water Pennywort is a name used for any species of the umbelliferous genus Hydrocotyle, low herbs with roundish leaves, growing in marshy places.

Penob'scot, a river of Maine. The West Branch rises near the Canadian frontier, and flows east and south-east to where it meets the East Branch or Seboois River. Afterwards its course is south-south-west to Penobscot Bay, a broad and sheltered inlet of the Atlantic Ocean, 35 miles long and 20 wide, with numerous islands. It is tidal and navigable for large vessels to Bangor, 60 miles from its mouth. The chief trade is in lumber.

Penrhyn. See CARNARVONSHIRE, BANGOR, BETHESDA, and SLATE.

Penrith, a market-town of Cumberland, in a picturesque and fertile valley, on the outskirts of the Lake District (q.v.), 18 miles SSE. of Carlisle. It has a fine old ruined castle, where Richard III. (then Duke of Gloucester) is said to have resided, and a grammar-school (1395; refounded 1564). In the churchyard are two ancient monuments, the 'Giant's Grave' and the 'Giant's Thumb,' often visited by Sir Walter Scott; and north-east of the town is the wooded Beacon (937 feet). There are sawmills, tanneries, and breweries. See works by J. Walker (1856) and G. Watson (1893). Pop. (1851) 6668; (1881) 9268; (1891) 8981.

Penryn (Corn., 'head of the river'), a town of Cornwall, at the head of a creek of Falmouth harbour, 3 miles NW. of Falmouth town, with which it returns one member to parliament (till 1885 two). Scarce a trace remains of Glasney College, founded in 1264 for thirteen Black Augustinian Canons; and none of a palace of the bishops of Exeter. Neighbouring quarries supply the famous Penryn granite—the material of Waterloo Bridge, the Chatham Docks, and other great public works; and the town has besides some manufactures of paper, woollen cloth, gunpowder, &c. Incorporated by James I., it was taken by Fairfax in 1646. Pop. (1851) 3959; (1891) 3256.

Pensacola, a port of entry and the capital of Escambia county, Florida, is 244 miles by rail ENE. of New Orleans, on the west shore of a deep bay opening into the Gulf of Mexico. The entrance is defended by Fort McRee and Fort Pickens, the latter on Santa Rosa Island; and near by is the Pensacola navy-yard, with a marine hospital and barracks. Pensacola contains foundries and lumber and planing mills, and ships large quantities of yellow pine. It was settled by the Spaniards before 1700, occupied by the British from 1763 to 1781, and afterwards during the wars with Napoleon, taken by Andrew Jackson from the British in 1814 and the Spaniards in 1818, and passed with the rest of Florida to the United States in 1819. Pop. (1880) 6845; (1890) 11,751.

Penshurst, a village of Kent, 4 miles SW. of Tunbridge; pop. 1673. Penshurst Place was the birthplace of Sir Philip Sidney and Algernon Sidney.

Pensionary, the name formerly given to the syndic or legal adviser in every important town of Holland, because receiving a salary or pension; and, during the republic of the United Netherlands, the state secretary for the province of Holland was called *Raadspensionaris*—Englished by State Pensionary, or, more commonly, Grand Pensionary. The Grand Pensionary had no vote in the assembly of the states, and could only bring forward the subjects of discussion. He, however, collected the votes, wrote the decrees, read the letters addressed to the states, conducted negotiations with foreign ambassadors and ministers, and took charge of the revenues of the province, and whatever else pertained to its welfare. The office was abolished in 1795, after the conquest of Holland by the French revolutionists. Olden Barneveldt, De Witt, and Heinsius were the most celebrated holders of this office.

Pensions may be broadly divided into two classes—superannuation allowances and rewards for special services. In Great Britain a sum of £1,500,000 per annum is required for superannuation in the various departments of state, including

the consular, diplomatic, and colonial services. The number of these pensioners in 1889–90 was 3258, and the grants for them are in the estimates classed among 'Non-effective and charitable services.' The pensions granted from the Civil List (q.v.) are altogether on a different footing from those in the civil service, which last are part of the condition of employment, and are thus somewhat in the nature of deferred pay. Of the same nature is the retired pay of army and navy officers, as well as the service-pensions to soldiers and seamen. Pensions to the widows and children of deceased servants of the state are often granted under the term of 'compassionate allowances.' The enormous character of the burden of the non-effective services has given occasion for much discussion, and has called forth many suggestions. Thus, in the session of 1888 a motion was carried in the House of Commons, the effect of which is to restrict the system of compulsory retirement on pension of civil servants. The principle has been laid down that officials no longer required in their own departments who are still able and willing to render service for the public money should be provided with employment in other departments, instead of being forced to become useless burdens upon the country. Perpetual pensions must be regarded as somewhat of an abuse of the principle upon which a state rewards good and faithful servants. The matter became the subject of a parliamentary inquiry on the initiation of Mr Bradlaugh in 1887. A select committee was appointed, which, after taking evidence of a curious and interesting kind, recommended that no more pensions or allowances should be granted in perpetuity. This committee also reported in favour of the abolition of all sinecure offices with salaries but no duties, and recommended that all existing perpetual pensions, allowances, and payments, and all hereditary offices, should be determined and abolished. In commuting such pensions it has been laid down as necessary to differentiate cases of grants for actual services by the original grantees, and cases of mere gratuity. Where no service or merely nominal service was rendered either by the present holder or the original grantee it was proposed that the payment should in no case continue beyond the life of the present holder. In former commutations of perpetual pensions a scale of twenty-seven years' purchase was usually adopted. On or about this scale there were, between 1881 and 1887, 330 pensions and allowances of the annual value of £18,957 commuted for a sum total of £527,933. The rate was reported to be too high, and in the session of 1888 a motion was passed for giving effect to the recommendation of the select committee, and for a return in detail of all outstanding hereditary pensions and the circumstances in which they were granted. Pensions such as those of £4000 per annum to the Duke of Marlborough, and of £5000 to Lord Nelson, and to their heirs in perpetuity, are, of course, well understood as in return for 'value received' in special services to the state. The objection to the principle of them is that it is a burdening of posterity with payment for services rendered to one generation. The rewards for distinguished services should be defrayed by the generation receiving the benefit of them, and should be conferred upon the persons who actually render them, either in the form of a capital sum down, or of a life-pension only.

There are, again, a number of hereditary pensions conferred not for services, but as *solatium* for the loss of the fees of abolished offices. Thus, when the offices of Custos Brevium and Clerk of the Juries were abolished in 1837 the holders were compensated with hereditary pensions of £786 each. These were commuted on a basis of twenty-seven years' purchase. One of the numerous perquisites conferred by Charles II. on his illegitimate son, the Duke of Grafton, was that of Officer of the Pipe, or Remembrancer of First Fruits and Tenths of the Clergy in the Court of Exchequer. This office was sold by the duke in 1765, and when the fees were abolished the holder was compensated with a perpetual pension of £62, 9s. 8d. A still more remarkable case was that of the hereditary office of Master of the Hawks, granted by James II. to the Duke of St Albans and his heirs for ever. The emoluments consisted of £391, 1s. 3d. as salary, £200 for four falconers, £600 for provision of hawks, and £182, 10s. for other provisions—together, £1373, 11s. 3d. This total was subsequently reduced to £965, at which it stood until commuted, in 1891, for £18,335, although there had been neither hawks nor falconers for many generations. A pension of £4000 per annum granted in 1779 to William Penn, the founder of Pennsylvania, and his heirs for ever, was in 1884 commuted for a ten years' annuity of £12,796, considered equivalent to twenty-seven years' purchase. In 1676 Charles II. granted to the Duke of Richmond and his heirs for ever a duty of one shilling per ton on all coals exported from the Tyne for consumption in England. One hundred years later that charge was converted into a perpetual pension of £19,000 (chargeable on the Consolidated Fund), which, again, was afterwards redeemed for £633,333, and invested in lands settled upon the duke and his heirs. The Duke of Hamilton, as Hereditary Keeper of Holyrood, has an hereditary pension of £45, 10s., and the descendants of the Heritable Usher of Scotland enjoy one of £242, 15s. These are a few of the examples of a wholly indefensible system. There are also limited hereditary pensions granted for a certain number of lives, which are not so unjustifiable, as, for instance, the pension of £4000 to the Duke of Wellington and two successors, and the pension of £2000 to Lord Napier of Magdala and one successor. In 1891 there were eight of these limited hereditary pensions in existence (viz. Lords Combermere, Gough, Hardinge, Keane, Napier, Raglan, Seaton, and the Duke of Wellington), most of which were in the possession of the last holder. It is probable that this system of reward for military services will also be discontinued. Pensions, but for life only, may be claimed by ministers who have held office under the crown (not necessarily continuously) for four years in the first class (£2000), six years in the second class (£1200), or ten years in the third class (£800). The following is a summary of the total amount paid by Great Britain in pensions, superannuations, and compassionate allowances: we take the figures for the fiscal year 1887–88, because that period coincides with the movement to terminate perpetual pensions:

Department.	No. of Pensioners.	Amount of Payments.
Civil Service	3,164	£467,582
Army	97,004	3,789,282
Navy	38,366	2,040,659
Perpetual and Civil List	1,072	431,608
Departmental	16,886	1,086,444
Total	156,492	£7,815,575

In round numbers the present outlay of the government of the United Kingdom in pensions and superannuations is 7½ millions per annum, of which quite 5½ millions go to the army and navy, and form a proper item in the cost of the national defence, although probably capable of better distribution. It is an open question how far the remaining 2 millions may be wisely expended, but for hereditary allowances the national accounts will not incur fresh charges, and existing charges are being equitably extinguished. On the Indian List there are set down 10,500

pensioners drawing £6,000,000, of which £2,500,000 belongs to the civil and £3,500,000 to the military department.

ARMY PENSIONS are temporarily granted to officers of the army severely wounded in action at the following rates, and if the wound entails the loss of an eye or limb, or an equivalent injury, the pension may be made permanent: Field-marshal, general, or lieutenant-general commanding-in-chief, a special rate; lieutenant-general, £400 a year; major-general or brigadier, £350; colonel or lieutenant-colonel, £300; major, £200; captain, £100; lieutenant and second-lieutenant, £70. These pensions may be held together with retired pay (see RETIREMENT). If an injury of similar character is received on duty, but not in action, a general officer receives a special rate of pension; a colonel or lieutenant-colonel, £250 a year; a major, £150; a captain, £75; and a lieutenant or second-lieutenant, £50. Pensions are also granted to the widows of officers dying in the service, at rates varying from £40 a year in the lowest rank to £120 in the highest, subject to an increase of 50 per cent. if the officer is killed in action. Compassionate allowance (£10 to £20, according to rank) is granted to their sons if under eighteen, and to their daughters if under twenty-one, increased by 25 per cent. if the father is killed in action. On remarriage a widow forfeits her pension, but on again becoming a widow it may be restored if she is left in need. If the mother or sisters of an officer killed in action were dependent upon him, compassionate allowances may be granted to them.

Warrant officers, after more than twenty years' service, may receive a pension varying from 3s. 6d. to 5s. a day, according to length of service, their widows £20, and their children £5 a year, with certain limitations.

Non-commissioned officers and *soldiers*, whether European or natives, are classed for pension according to rank and service in that rank, the highest daily rate being 2s. 9d. and the lowest 6d. No soldier of less than fourteen years' service is entitled to a pension, except for injuries sustained in action or on duty, when the rates vary from 6d. to 3s. a day, according to rank, service, extent of the injury, and other considerations, and the pension is not made permanent until a medical board has pronounced the injury to be a permanent disability. A special pension, in addition to any other, of £10 a year is granted to every soldier who has gained the Victoria Cross, and an addition of £5 is granted for each further act of bravery. Medals, with annuities not exceeding £20, are granted to soldiers above the rank of corporal who have performed distinguished or meritorious services, and are selected by the commander-in-chief. These annuities are in addition to pension.

NAVY PENSIONS were first instituted in the reign of William and Mary; those for officers may be classed as follows: Good-service pensions, Greenwich Hospital pensions, pensions for wounds, and the ordinary pension to which an officer may be entitled on retirement, now known as retired pay. No officer is entitled to a retiring pension until he is forty years of age; should he retire earlier he receives merely the half-pay of his rank. The amount of the retired pay depends upon an officer's rank, length of service, and age. The maximum retired pay of an admiral is £850 a year, for which thirty years' sea-service as a commissioned officer is requisite; he may in addition hold a good-service pension of £300 a year. The maximum retired pay of vice-admirals, with twenty-nine years' service, is £725 a year; that of rear-admirals, with twenty-seven years' service, £600; of captains, with twenty-seven years' service, £600; of commanders, with twenty-one years' service, £400; and of lieutenants, with nineteen years' service, £300. The retired pay of officers of other branches of the service is calculated in the same way, on length of service and age. The good-service pensions, so-called, consist of ten of £300 a year for admirals, which may be held after retirement, and of twelve of £150 a year for captains; these last are conferred on captains on the active list, and are relinquished when their holders are promoted to rear-admiral or retire. Pensions for wounds are conferred on officers and men; they range from small yearly sums, according to rank of holder and nature of wound, to a maximum of £200 a year.

All seamen and marines are entitled to a pension after twenty-one years' service from the age of eighteen, or from the date of enlistment; this pension ranges from 10d. a day to a maximum of 1s. 2d. a day, the increase depending upon the number of good-conduct badges a man may have; of these he may have three, and he receives an additional 1d. a day for each, and, if he holds a good-conduct medal, an additional penny for that. Petty officers, in addition to the rates of pension awarded them as seamen, are allowed for each year's service in the capacity of superior petty officer 15s. 2d. a year, as junior petty officer 7s. 7d. There still remain the Greenwich Hospital pensions, which are held in addition to the ordinary pensions. The idea of establishing a hospital for infirm and disabled seamen originated with Mary, the consort of William III., and Sir Christopher Wren was employed to build an additional wing to Greenwich Palace. The king granted £2000 a year towards it, large subscriptions were added by noble and wealthy people, forfeited and unclaimed prize-money and various grants were given, and finally the forfeited estates of the Earls of Derwentwater were added to the endowment. The revenue of the hospital is now about £167,000 a year. The Greenwich Hospital pensions are divided as follows: Ten of £150 a year for admirals, six of £80 a year for captains, twenty-three of £65 for commanders, and forty-six of £50 a year for lieutenants; three of £80 and seventeen of £50 a year for officers of the old navigating branch, and fifty-seven varying from £100 to £50 a year for officers of the civilian branches of the service. There are fifty-two of £35 and £25 a year for warrant officers. The Greenwich Hospital pensions for the men are termed 'age' and 'special' pensions. They are given entirely at the discretion of the Admiralty, and are not granted to any person whose character whilst in or after leaving the navy has not been good. A naval pensioner is eligible for the age pension of 5d. a day on attaining the age of fifty-five, if he has been in receipt of his pension for five years; and for the increase of such age pension to 9d. a day at the age of sixty-five, if he has been in receipt of his naval pension for ten years. Age pensions are given to naval pensioners only, and the number of pensions in force at any one time is not to exceed 7500; the vacancies to be filled by those whose health renders them completely incapable of earning a living.

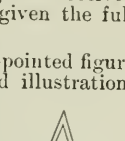
Special pensions are given at the discretion of the Admiralty to men unable to contribute materially to their own support, and vary in amount and duration according to each man's degree of disability and the other circumstances of his case; the amount of the fund from which these pensions are given is limited to £22,000 a year. They are tenable in addition to naval and age pensions; these pensions range from 6d. to 1s. 3d. a day.

Widows of officers of royal navy and marines are allowed pensions, and their children compassionate allowances. These cannot be claimed as a right, and, except in the case of pensions conferred on widows of officers killed in action or dying from wounds or other special causes, are not granted to

widows whose private incomes may exceed a certain scale which is fixed by the Admiralty. These pensions in ordinary cases range from £120 to £40 a year. In the case of officers killed in action their widows, however, may receive a maximum pension of £200 a year. Compassionate allowances to children may be continued in the case of sons until they attain the age of eighteen, and of daughters until they marry or attain the age of twenty-one, but no longer, except in very special cases. These allowances vary from £5 to £20 a year. Gratuities, pensions, and compassionate allowances are made to widows and children of petty officers and men at the discretion of the Admiralty, but there is no fixed scale.

The Pension System of the United States presents two peculiar features, in the almost entire absence of a civil list, and the non-recognition of long service as a ground for pension. Generally speaking, pensions are granted only for active service in time of war, and therefore the beneficiaries are the survivors (or their widows and children) of the armies of volunteers and conscripts who took part in the country's several wars. What are called 'service pensions' have been granted to survivors of the War of the Revolution (under Act of 1818; the last pensioner under this act died in 1867, aged 101, but the last Revolutionary pensioner under a special act, not till 1869, aged 109), the War of 1812 (under Act of 1871), and the Mexican War (under Act of 1887), or to their widows (37 survived in 1888). But the bulk of the United States pensions are 'invalid pensions,' for total or partial disablement from wounds or disease contracted in the military or naval service; the widows and minor children under sixteen years of age of those who have died from such wounds or disease; or, in the event of no such widows or minor children surviving, then the dependent mothers, fathers, or minor brothers and sisters of officers or men so dying. The pensions, which range from $24 to $2000 per annum, are graded, and many specific wounds and disabilities are scheduled and priced. Thus, where the regular aid and attendance of others is required, from $50 to $72 a month is paid; where the beneficiary is incapacitated for manual labour, $30 a month; for the loss of a hand or foot, or total deafness, $30, but of both feet or hands, or both eyes, $72 a month; and for amputation at the shoulder or hip joint, $45. Widows of privates receive $12 a month; dependent relatives the same; children $2 each, but if the widow does not survive they receive their pension jointly. Widows or dependent relatives of officers receive from $15 to $30 a month. The pension of widows ceases when they marry. For the administration of the pension system an independent bureau was created in 1833; since 1849 it has been a bureau of the Department of the Interior. Under the commissioner, who is appointed by the president, there are nearly 2000 persons employed in the settlement of claims for pensions; and besides there are nearly 3000 surgeons throughout the country engaged to examine applicants. The following figures show plainly enough the enormous growth of the American pension system. In 1862 the disbursements slightly exceeded $790,000, in 1872 they exceeded $30,000,000, in 1882 $54,000,000; while in 1888 they were over $82,000,000, in the next year over $87,000,000, in 1890 $109,357,534, and in 1897 $140,000,000. In June 1890 a Dependent Pension Law was passed, under which in three months 460,282 claims were received. In 1897 pensions swallowed nearly one-third of the revenue of the republic (while 500,000 claims were still awaiting adjudication!), and represented a greater cost than the British or the German imperial army.—It may be added that, by an act of 1882, widows and minor children of keepers or crew of a life-saving or lifeboat station who perish in or from injuries received through the life-saving service are given the full pay of the deceased for two years.

Pentacle, or PENTAGRAM, a five-pointed figure of the form shown on the annexed illustration, which occurs on old Greek coins, and was used as a symbol of mystery, perfection, or of the universe by Pythagoreans, Neoplatonists, and Gnostics. It occurs on Abraxas Stones (q.v.), and was used as the device of various secret societies, some of them masonic, and hence appears in ecclesiastical architecture (as at Rouen). The 'wizard pentagram' was, in the middle ages, a symbol powerful in repelling evil spirits, and is familiar to readers of Goethe's *Faust*. On the doors of cow-houses it was held to keep off witches. The pentacle, also called *pentalpha*, is often confused with the hexagram, composed of two equilateral triangles, which was also used as a magic symbol in astrology, alchemy, and cabalistic lore. See CIRCLE (MAGIC).



Penta'crinus. See CRINOIDEÆ.

Pentamerone, a famous collection of fifty folk-tales (Naples, 1637), written in the Neapolitan dialect, by Giambattista Basile, which are supposed to be told during five days by ten old women for the entertainment of a Moorish slave who has usurped the place of the rightful princess. An admirable German translation (enriched by notes) by Felix Liebrecht appeared at Breslau in 1846. Thirty-one of the stories were translated by J. E. Taylor (1848); Sir Richard Burton printed a complete English translation in 1893 (2 vols.). (For the *Decameron* and the *Heptaméron*, see BOCCACCIO, MARGARET OF NAVARRE). The Pentameron stories are of the greatest value to the student of folk-tales.

Pentamerus Beds, in Geology, a name formerly applied to the upper and lower Llandovery rocks, owing to the abundance of the brachiopods called Pentamerus. See SILURIAN SYSTEM.

Pentapolis. See CYRENAICA.

Pentateuch, a Greek word (*pentateuchos*) meaning 'the five-volumed (book),' is the name used by Origen to denote what the Jews of his time called 'the law' (*Torah*) or, more fully, 'the five-fifths of the law.' The same word was adopted into the Latin by Tertullian. 'The five books of Moses' as a designation of the Pentateuch was first made current in the Western Church at a considerably later period by Jerome and Rufinus; but a Jewish writer (Josephus) had long before stated that the first five books of the Old Testament canon 'belong to Moses.' The Greek names by which the five books are now known—Genesis, Exodus, Leviticus, Numbers (Arithmoi), Deuteronomy—have come to us from the Septuagint through the Vulgate Latin. Along with the book of Joshua these five really form one continuous work, now usually referred to by modern scholars as the Hexateuch, the present division of the Hexateuch having been made by a comparatively late editor. The Mosaic authorship of the Pentateuch is nowhere affirmed in the books themselves, but it is suggested by certain obvious phenomena in various parts of them, though contradicted by others; and it had begun to be held before the Jewish canon was closed ('the law of Moses,' Dan. ix. 11, 13; 'the book of Moses,' 2 Chron. xxv. 4, xxxv. 12). It soon became a fixed ecclesiastical tradition and a tacitly established point of Christian orthodoxy, and those who doubted or denied it were generally held to be, and in fact often were, hostile to Christianity (Hobbes, Spinoza),

though this cannot be said of Leclerc, Simon, or Morinus. The facts which have generally led scholars with steadily increasing unanimity to a contrary conclusion have already been indicated under BIBLE, where the leading documents—JE (Jahvist + Elohist), D (Deuteronomy), and P (Priestly history and Priestly legislation)—have been named and characterised. The present article will seek to describe these documents with rather fuller detail and to indicate briefly what is maintained by many modern critics as to the nature of the somewhat complex process by which they have reached their present state of combination.

(I.) *JE.*—This is compounded mainly from two older parallel narratives, both of which embodied in writing current oral tradition relating to the origin of the world and of man, and to the patriarchal and heroic periods of Hebrew history. The extent of the document as we now have it may be ascertained roughly by deducting D and P (see below) from our present Hexateuch, allowance being also made, however, for editorial additions and glosses. The separation of its two constituent elements is a problem of greater delicacy and difficulty. (1) The work of the Jahvist, which employs the name Jahweh (see JEHOVAH) throughout, is distinguished also, on the whole, by other well-marked characteristics, especially a naïve anthropomorphism, which appears more particularly in its frequent accounts of Divine appearances under the form of 'the angel of Jehovah,' as, for example, to Abraham, to Lot, and to Moses at the inn and also on Pisgah. The style is lively, vivid, and popular. The author shows special interest in the local sanctuaries which were still recognised in his own time, showing that they owed their origin to theophanies in the pre-Egyptian period. His decalogue is that ancient and simple form of the law contained in Ex. xxxiv. He introduces, at various places, extracts from older poetical works, such as Gen. xlix. and the quotations from 'the book of the wars of Jehovah.' For minute details as to the limits of his work reference must be made to some of the books mentioned in the bibliography appended to this article; among the more important passages in Genesis which can with considerable certainty be attributed to him are the account of the creation and fall in ii. 4*b*-iv. 26; portions of vi.; one of the two parallel accounts of the flood contained in vii., viii.; the history of Abraham in xii., xiii., xv., xvi., xviii., xix., xxiv., and xxv. 1-6; of Isaac in xxv. 21-34, and xxvi.-xxvii.; considerable portions of the history of Jacob, including one of the narratives which make up chap. xxxiv.; portions of xxxvii., the story of Judah (xxxviii.); the story of Joseph in xxxix., xliii., xliv., xlvii. and l. (also some fragments in the intervening chapters). (2) The Elohist, who in the book of Genesis invariably employs the name Elohim, has several distinguishing characteristics. He shows some beginnings of a tendency to remodel the ancient traditions in a less anthropomorphic sense. He does not speak of objective manifestations of the Deity under human form as the angel of Jehovah, but prefers rather to represent divine communications as being by dreams, visions, and voices. It has been remarked that he takes a special interest in the sanctuary of Beersheba. His decalogue, if later expansions be left out, is that contained in Ex. xx. He no doubt originally had an account of the creation and fall parallel to that of the Jahvist; but the earliest extant fragment of his work is probably that preserved in Gen. xv. 5. To him are attributed Gen. xx. 1-17, xxi. 6*a*, 8-32*a*, the greater part of xxii., considerable portions of xxvii., xxix., and xxx.-xxxii., xxxv. 1-8, almost the whole of xl.-xlii. and some portions of the remaining chapters; Ex. i. 6, 8-12, 15-22, ii. 1-10, 15, iii. 1-6, 9-16, iv. 17-23, v. 1, 3, 5-23, vi. 1, vii. 17, 18, 20, 21, ix. 22-26, 31, 32, x. 12, 13*a*, 14*a*, 21-29, a few verses of xi. xii., xiii. 17-19, xiv. 7, 9, 16, 22, xv. 20-25, xvii. 3-16, xviii., xix. 2, 3, 10, 13-17, 19, xx. 1-23 (with later additions), xxiv. 3-8, 12-14, 18*b*, xxxi. 18, xxxii. 15-20, 25-29, xxxiii. 1-3, 5-11; Numb. x. 33-36, xi. 1-3, 7-10, 30-34, xii. 1-15, xiii. 20, 23, 24, 30-33, xiv. 39-45, portions of chap. xvi., xx. 3-11, 13-21, xxi. 12-30, portions of the story of Balaam, xxv. 3, 5, xxxii. 16, 17, 24, 34-39, 41, 42; Deut. xxxi. 14-23, xxxii. 44, xxxiii., xxxiv. 10.

That J and E once existed as separate narratives is now unanimously agreed, and that their dates must be sought somewhere between 900 B.C. at the earliest and 750 at the latest may also be regarded as settled. Within these limits there is considerable diversity of opinion. It is agreed on the whole that E belonged to the northern kingdom, and many hold this of J also, but some of the strongest critics think of the Jahvist as having been a Judæan. There is disagreement also as to the relative ages of the two, some thinking E the older, but the preponderance of argument seems to be in favour of J. The two were brought together into the document now known as JE by a redactor (sometimes called for convenience' sake the Jehovist, as distinguished from the Jahvist) towards the end of the 7th century. His aim was to embrace the two parallel histories; and his method was simple. Where the two were closely parallel he seems to have chosen the one he thought the preferable and to have cancelled the other (saving occasionally a word or clause); when he found the same incident related of different persons and in very different forms, such as the incident of Abraham and Sarah at Pharaoh's court, and Isaac and Rebekah at Abimelech's, he gave both, introducing some reconciling notes (e.g. Gen. xxvi. 18). A good example of his manner of combination is afforded by the narrative of Jacob's dream. JE also introduced new matter. In particular, the legislative portion of his work, usually spoken of as the Book of the Covenant (Ex. xx. 24-xxiii. 33, xxiv. 28), shows the influence of the Assyrian period, and (it is held) cannot be earlier than the 7th century (but prior to the publication of Deuteronomy).

(II.) *D.*—Deuteronomy also is a composite work, and its various elements are not all of the same date. In structure it consists of a legislative kernel (xii.-xxvi.), to which are prefixed two separate introductions (i. 1-iv. 44, and v. 1-xi. 32) and two separate epilogues or concluding narratives (xxvii. and xxviii.-xxx.). Finally, the last four chapters form an appendix containing some materials from J and E. Critics are now generally agreed that the original Deuteronomy to which reference is made in 2 Kings is what we have spoken of as the legislative kernel. The date of its publication we know to have been 621 B.C. That of its composition is less certain, but no one now proposes to carry it back to an earlier date than the reign of Hezekiah. There is difference of opinion as to the authorship of the prologues and epilogues. The second introduction and first epilogue, if by the author of the central portion of the book, were probably written at least at a later date. The first introduction, recapitulating portions of the history of JE, and the second epilogue, containing unmistakable allusions to the exile, are believed to have been the work of a second Deuteronomistic writer about the beginning of the 6th century. A third Deuteronomistic redactor towards the close of the exile (about 536 B.C.) combined JE with D, and gave what is known as the Deuteronomistic redaction to the

historical books 1 Samuel to 2 Kings. But the so-called Deuteronomistic redaction was perhaps not a single or final act; some think it did not wholly cease till the beginning of the Grecian period. Considerable portions of the Book of Joshua are probably due to one of the Deuteronomists—e.g. i., iv. 21–24, viii. 30–35, xi. 10–23, xii. 1–24, xiii. 1–14, xiv. 6–15, xxii. 1–6, xxiii.

(III.) *P.*—Of all the elements of the Hexateuch by far the bulkiest (see BIBLE, Vol. II. p. 120, and add Josh. xiii. 15–33, xiv. 1–5, xv. 1–12, 20–62, xvi. 4–8, xvii. 1–9, xviii. 11–28, xix.–xxi.–xxii. 9–34) is that supplied by the so-called Priestly document. It is also the most easily distinguishable, and even those critics who differ most widely as to its age are agreed almost to a verse as to its extent. The criteria which they apply are certain well-marked features in its highly developed and esoteric ritual legislation, and, as regards its narrative portions, a certain mechanical precision with which it follows a formal arrangement of its matter, and heads each section with a title, the apparent accuracy of its chronological, genealogical, and statistical details, and, along with that, an almost entire absence of the picturesque elements which give their chief literary charm to J and E. In the opinion of a rapidly increasing number of critics the evidence for its relatively late origin is overwhelming. The argument is drawn not only from the characteristics of its legislation and history already alluded to, but also from its language and phraseology, from the fact that it is never alluded to in what are certainly known to be the pre-exilic books of the Old Testament canon, and from the absence of Deuteronomistically revised passages. As Deuteronomy is associated with Josiah's reformation, so is the Priestly legislation with that of Ezra. It, however, contains some elements which are earlier than that event (444 B.C.) and others which are later. Of an earlier date, in particular, is what critics call the Law of Holiness contained in Lev. xvii.–xxvi., presenting affinities with the last chapters of Ezekiel. The cessation of the temple functions with the beginning of the exile naturally led to a desire and effort on the part of zealous priests to preserve some memorials of the pre-exilic temple practice apparently threatened with oblivion; but further, it would seem, the lapse of time gave scope for a good deal of reflection and discussion about questions of detail with a view to possible improvements, and this was especially the case when it became plain that in the restored community the priesthood were destined to hold a much more prominent position than at any period of the monarchy. With the practically new detailed code which resulted was associated a brief summary of general history and of the history of Israel, the result being a work of combined legislative and narrative character similar to the previously existing JE + D which it was designed to supersede. Critics also discern further modifications of ritual which must be assigned to a later date than that of Ezra (see NEHEMIAH); but the investigation of these is still being carried on, and cannot be regarded as completed. When it was found that the Priestly document was only very slowly, if at all, superseding JE + D as an authoritative history and law book, the important step of incorporating it with that document was next taken. The work thus produced, probably before 400 B.C., was substantially our present Hexateuch. But it continued to undergo a process of editorial change and revision till a much later date. The division of the Hexateuch into the six books with which we are now so familiar is probably one of the last editorial operations it underwent, and carries us back, as we have seen, to at least the date of the LXX. translation.

The gradual ascertainment in modern times of the different sources of the Hexateuch has been described by Stade with hardly undue exaggeration as one of the most brilliant triumphs of human sagacity. The investigation of the problem on scientific lines may be said to have begun with Astruc (1753), who was the first to point out the value of the 'Jehovah' and 'Elohim' criteria in seeking to trace the authorship of different parts of Genesis. His hypothesis was introduced into Germany by Eichhorn, and was the beginning of a long discussion which has lasted till the present day, producing an immense literature, now for the most part quite out of date, and a vast variety of conflicting and, as was sometimes imagined, mutually destructive theories. The first cardinal fact to emerge from the chaos with clearness was the late date of Deuteronomy as being the new law book which formed the basis of Josiah's reformation. The credit of having established beyond doubt the post-Mosaic authorship of Deuteronomy belongs chiefly to De Wette, whose activity dates from 1805. The next thing to be satisfactorily proved was the existence of two independent Elohists. The existence of two authors sharing the feature in common had been divined by Ilgen (1798), but it was always supposed that the one merely supplemented the other, till Hupfeld (1853) proved their complete independence. In other words, four distinct sources were now completely made out. Finally, Graf (1866) proved the post-exilic character of the legislative portion of the Priestly document (hitherto spoken of as the 'Grundschrift' or older Elohist), and it was further shown by Kuenen to the satisfaction of Graf himself that the same character belongs to the Priestly document as a whole. This indeed had been seen and argued for at an earlier date by Vatke (1835) and George (1835), but partly through defects in their manner of presenting their views, and partly because scientific and theological opinion was not yet sufficiently educated to receive it, it failed to make any impression. Reuss, Graf's teacher, claimed to have publicly taught the Grafian theory as early as 1833; but he did not publish it till 1879.

As a manual of modern Pentateuch criticism Kuenen's masterly *Historico-critical Inquiry into the Origin and Composition of the Hexateuch*, translated from the Dutch by Wicksteed (1886), is indispensable to the student, and will probably hold a permanent place as a classical example of the application of modern methods in biblical criticism. The 'Introduction' prefixed to it, containing an outline of the history of Hexateuch criticism since 1861 will serve as guide to the older literature. Along with Kuenen's great treatise ranks Wellhausen's equally admirable *Composition des Hexateuchs* (2d ed., with appendices, 1889). Only the appendices to this work are new, the papers on the composition of the Hexateuch having appeared originally in the *Jahrbücher f. deutsche Theol.* in 1876–77, and having been reprinted without modification in 1885.

Valuable assistance of a typographical or mechanical kind is to be had from Kautzsch and Socin's little work entitled *Die Genesis mit äusserer Unterscheidung der Quellenschriften* (2d ed. 1891), in which the various sources and the work of editors and glossators are indicated by the use of differential types. In Kautzsch's new translation of the Old Testament (*Die Heilige Schrift des A. T.*, 1890–91), P, J, E, D, Dt, and R in the Hexateuch are indicated by letters on the margin. See also Lenormant's *Genèse* and Reuss's *Bible*. The critical views indicated in the foregoing article are more or less fully discussed, and the results reckoned with, in the histories of Israel by Wellhausen (*Prolegomena to the History of Israel, with reprint of article 'Israel' from Ency. Brit.*, 1885), Stade (*Gesch. d. V. Isr.*, 1887), Renan (*Hist. du Peuple Isr.*, 3 vols. 1887–91; Eng. trans.), and Kittel (*Gesch. d. Hebräer*), whose first half-volume (1888) gives in a very instructive way the stories of the patriarchal age according to E, J, and P respectively, in

three separate sections, followed by estimates of the historical meaning of each narrative. Dillmann placed P two centuries before the exile; Nöldeke and Schrader still argue for its comparatively early date; Baudissin dates it about thirty years before D. See also Holzinger's *Einleitung in den Hexateuch* (1893). For a fuller bibliography Reuss's *Gesch. der heiligen Schriften Alten Testaments* (2d ed. 1890) may be consulted; see also article BIBLE, Vol. II. p. 128–9; and SAMARITAN PENTATEUCH.

Pentecost (Gr. *pentēcostē*, 'fiftieth') was the name given to the Jewish feast held on the fiftieth day after the Passover, in celebration of the 'in-gathering,' and in thanksgiving for the harvest (see FESTIVALS). From the Jewish use it was introduced into the Christian, and with special solemnity, as being the day of the descent of the Holy Ghost on the apostles, and of the first solemn preaching of the Christian religion. From early times pentecost has been regarded as one of the great festivals of the Christian year, and it was chosen as one of the times for the solemn administration of baptism; and the English name of the festival, *Whit-Sunday*, is derived from the *white* robes in which the newly-baptised were clad. It is regarded as specially sacred to the Third Person of the Blessed Trinity. Many curious usages were anciently connected with the celebration. The figure of a dove (an emblem of the Holy Ghost) suspended by a cord from the ceiling was in some churches lowered so as to alight on the high altar during the service; in others figures of cloven tongues were similarly introduced. In some places in the East, and in the West too, the practice prevails of decorating the churches with evergreens and flowers, as is done in England at Christmas.

Pentelicus. See ATHENS (p. 536), and MARBLE.

Pentland Firth, a channel between the Atlantic and German Oceans, separating the mainland of Scotland from the Orkney Islands. It is 14 miles long and 6¼ miles broad at the narrowest. The Pentland Skerries, 5 miles north-east of Duncansbay Head, consists of two islets and of several contiguous rocks. On the larger of the islets is a lighthouse (1794). The navigation of the Pentland Firth is more dangerous than that of any other portion of the Scottish seas, a current from west to east flowing through it with a velocity of from 3 to 10 miles an hour, and causing numerous eddies and whirlpools. Yet over 5000 vessels with cargoes pass through the Firth annually.

Pentland Hills, in the Lowlands of Scotland, extend 16 miles south-westward from a point 3 miles south of Edinburgh, through the counties of Midlothian, Peebles, and Lanark, have a breadth of 4 to 6 miles, and attain a maximum height in Carnethy (1890 feet) and Scald Law (1898). In the battle of the Pentlands or Rullion Green, 2 miles NNW. of Penicuik, Sir Thomas Dalyell routed 900 westland Covenanters, 28th November 1666.

Pentonville, a populous district in London in the parish of St James's, Clerkenwell, the first buildings in which were erected in 1773 on fields belonging to Henry Penton, Esq. The name has since been extended to part of the parish of Islington, in which stands the *Pentonville Prison*. This, the *Model Prison*, as it was at first called, in the Caledonian Road, was built in 1840–42, and constructed on the radiating principle, so as to admit of thorough inspection, and contains accommodation for 520 prisoners. The treatment is designed to 'enforce strict separation, with industrial employment and moral training.' See *Report of the Directors of Convict Prisons* (periodically).

Pentremites, fossil Crinoids common in the Carboniferous System (q.v.).

Pentstemon, a genus of plants belonging to the natural order Scrophulariaceæ, consisting of herbaceous or sub-shrubby species mostly yielding flowers of great beauty. The genus is wholly American, mostly belonging to the warmer states, and few of them are hardy enough to endure the winter climate of Britain, where consequently they are propagated annually by cuttings, which are protected in frames during winter and planted in the flower-garden in March or April. The general character of the inflorescence of Pentstemon is so well known as to require no description here. The numerous garden varieties of *P. gentianoides*, *P. Hartwegii*, and others are among the most popular of garden flowers. But there are many species even more beautiful than these, which are occasionally to be met in collections of rare plants. Of such may be mentioned *P. Jeffreyanus*, *P. Secundiflorus*, *P. Murrayanus*, *P. miniatus*, and others, as being exceptionally beautiful in colour.

Penumbra. See ECLIPSES.

Penza, a large rural town of Russia, 330 miles by rail SE. of Moscow, has a cathedral (17th century), a botanical garden, and manufactures of paper, soap, &c. Pop. 47,701.—The *government* has an area of 14,997 sq. m., and its population of a million and a half are chiefly engaged in agriculture.

Penzance (Corn., 'holy headland'), a town of Cornwall, the most westerly in England, at the head of Mount's Bay, 10 miles ENE. of Land's End, 80 W. by S. of Plymouth, and 328 (by road 281) WSW. of London. Standing on a finely-curved shore surrounded by rocky eminences, it is famous for its mild, equable climate, though the annual rainfall is heavy (43 inches). Its fine esplanade commands splendid land and sea views; and its chief buildings, constructed largely of granite, include a market-hall (1837) with a statue before it of Sir Humphry Davy (q.v.), an infirmary (1874), a post-office (1883), and public rooms (1867), Italian Renaissance in style, and comprising a guildhall, museum, library, &c. The harbour has two piers (1772–1845) half a mile long, forming a tidal basin of 21 acres; and docks have been added since 1882. Penzance is a headquarters of the mackerel and pilchard fisheries; market-gardening is an important industry; and of recent years the place has grown much in favour as a watering-place. Burned by Spaniards in 1595, and sacked by Fairfax in 1646, it was incorporated in 1614, and from 1663 to 1838 was one of the five 'coinage towns.' Pop. (1851) 9214; (1891) 12,448. See works by Lach-Szyrma (1878) and Millett (1876–80).

Peonage, a system of agricultural servitude common in Mexico (q.v.) and some other parts of Spanish America. The peon in debt to his employer was by the Spanish colonial system bound to labour for his employer till the debt was paid. Peonage in New Mexico was abolished by act of congress in 1867: it was also abolished in the Argentine Republic.

Peony (*Pæonia*), a genus of plants of the natural order Ranunculaceæ, having large showy flowers composed of five leafy herbaceous sepals, 5 to 10 petals, numerous stamens, and 2 to 5 carpels, each with numerous round, black, shining seeds. The leaves are compound, the leaflets variously and irregularly divided. The fibres of the root are often thickened into tubers. The species are large herbaceous perennials, or rarely half-shrubby, natives of Europe, Asia, and the north-west of America. None of them are truly indigenous in Britain, although one (*P. corallina*) is undoubtedly naturalised on Steep Holme Island in the Severn. On account of the beauty of their flowers, some of them are much cultivated in gardens, particularly the Common Peony (*P.*

officinalis), a native of the mountain-woods of the south of Europe, with carmine or blood-red flowers. A variety with double flowers is common. The White Peony (*P. albiflora*) is another favourite species, of which there are now many beautiful varieties which have originated in French and Belgian gardens. It is a native of the central parts of Asia. Its flowers are fragrant. The Tree Peony, Chinese Peony, or Moutan Peony (*P. Moutan*), is a half-shrubby plant, a native of China and Japan. In favourable circumstances it attains a very large size, and a height of 12 feet or more. It has long been cultivated in China and Japan; and is now also a favourite ornamental plant in the south of Europe, but is too tender to endure the climate of Britain, except in the most favoured parts; it is, however, often to be met with in conservatories, being of a very distinct and ornamental character when in flower. It flowers in spring. The varieties in cultivation are numerous. It is propagated by cuttings and also by grafting. The roots of most of the peonies have a nauseous smell when fresh, and those of the Common Peony were in high repute among the ancients as an antispasmodic—hence the name Peony, from *Paion*, a Greek name of Apollo, the god of medicine; but their medicinal properties are now utterly disregarded. The globose, shining black seeds of peonies were formerly, in some countries, strung into necklaces, and hung round the necks of children, as *anodyne necklaces*, to help them in cutting their teeth.

Peony.

People's Palace, an institution at Mile End Road, intended as a centre for amusement and recreation, and of association as well, for the inhabitants of the East End of London. It comprises a large hall, technical schools, art-galleries, concert-rooms, a library, reading and recreation rooms, swimming-bath, gymnasium, &c. It is the revival and development of an idea of the Beaumont Philosophical Institute; but the idea was first amplified and made really popular in Mr Besant's novel, *All Sorts and Conditions of Men* (1882). The buildings were inaugurated by the Queen, May 14, 1887, and work was begun on 3d October. The Queen's Hall, which is 130 feet long by 75 feet wide, can seat 2500 people. Around the hall are the statues of twenty-two queens, and a large organ at the north end. The technical and handicraft schools in 1890 were attended by 5000 pupils; they owe their foundation to the Drapers' Company of London, which has contributed in all about £60,000 to the People's Palace. Cheap concerts, at from 1d. to 3d. admission, have been well patronised, as also the picture exhibitions, swimming-bath, gymnasium, and dances. The evening classes attracted in 1898 an attendance of 950, for such subjects as elocution, physiology, drawing, machine construction, bookbinding, and tailors' cutting.

See Besant's *All Sorts and Conditions of Men*; Sir E. Hay Currie's *Working of the People's Palace; Nineteenth Century*, February, 1890; *Century*, June 1890.

Peoria, capital of Peoria county, Illinois, on the west bank of the Illinois River, at the outlet of Peoria Lake, 161 miles by rail SW. of Chicago. It is an important railway centre—the Union Depôt accommodates ten of the railways that meet here—and is connected by steamboat navigation with the Mississippi and by canal with Lake Michigan. It contains a Roman Catholic cathedral, a high school, a medical college, and three hospitals. The streets are wide, and there are ten parks, the largest Jefferson (35 acres). Mines of bituminous coal supply the city's numerous manufactories. These include especially the great distilleries, for which the place is noted, and breweries, foundries, and manufactories of flour, oatmeal, and starch, glucose, pottery, &c. In the lower city are large stockyards. Pop. (1880) 29,259; (1890) 49,758.

Peperino, a variety of tuff, met with in the Alban Hills near Rome. It is dirty grayish brown to white, earthy, and granular, and contains crystals of mica, leucite, augite, &c., with fragments of limestone, basalt, and leucite-porphyry.

Pepin, or Pippin, surnamed 'the Short,' king of the Franks, was the son of Charles Martel and the father of Charlemagne, and founder of the Frankish dynasty of the Carlovingians (q.v.). Charles Martel shortly before he died divided his kingdom between his two sons, Carloman and Pepin, Carloman taking the German part, and Pepin the Neustrian or territories in northern France; still they were only rulers (dukes) in the name of the Merovingian king. Carloman, after six years of office or rule, was persuaded by the English monk Boniface to enter (747) the monastery of Monte Cassino; his duchy passed over to Pepin. St Boniface in 751 crowned Pepin king of the Franks at Soissons, Childeric, the last of the *fainéant* Merovingians, having been deposed and his very able substitute chosen king in his stead. Pepin rested his power in great part upon the bishops and monks; accordingly, when Pope Stephen III. was hard pressed by the Longobards (Lombards) under Aistulf, he came (754) to France to solicit help from the new king of the Franks. Pepin led an army into Italy, compelled Aistulf to become his vassal, gave to the pope the title of exarch (of Ravenna), a title of the Roman empire, and so, by this 'Donation of Pepin,' laid the foundation of the temporal sovereignty of the popes; himself he made 'patrician of the city of Rome'—all this in 756. The church in his own dominions he placed under the supremacy of the pope. The rest of his life was spent in semi-crusading wars. Before going to Italy he had already attempted to convert the heathen Saxons at the sword's point; he went on with the 'holy' work in 757. Then he drove the Saracens back over the Pyrenees (758) and made (760–768) repeated incursions into Aquitania, though he never permanently conquered it. He died in 768, and his sons Carloman and Charlemagne divided his territories between them.—There were other rulers of this name amongst the Carlovingians. Pepin of Landen (died 639), with the help of Bishop Arnulph of Metz, was appointed *major domus* or viceroy of Austrasia under Lothair II.—Pepin of Heristal (died 714), his grandson, succeeded as mayor of the palace in Austrasia, to this added after 687 the similar viceroyalties of Neustria and Burgundy, and called himself 'Duke and Prince of the Franks.' He was their real ruler during the reigns of the puppet kings Theodoric, Ludwig III., Childebert III., and Dagobert III., and fought successfully against the Frisians, the Alemanni, and the

Bavarians.—Pepin, the son of Charlemagne, who was born in 778, was crowned king of Italy in 781, fought against the Avars, the Slavs, and the Saxons, drove the Saracens out of Corsica, and conquered Venice (810). He died in 810.—Pepin, son of Louis the Pious, was made king of Aquitania, revolted twice against his father and deposed him, but finally restored him, and protected him until he himself died (838). See Carlovingians, France.

Pepper (*Piper*), a genus of plants of the natural order Piperaceæ (q.v.), which once included the whole of that order, but, as now limited, consists of plants with woody stems, solitary spikes opposite to the leaves, and flowers on all sides, the flowers mostly hermaphrodite. The most important species is Common or Black Pepper (*P. nigrum*), a native of the East Indies, now cultivated also in many tropical countries; its berry or drupe being the most common and largely used of all spices. It is a rambling and climbing shrub, with smooth and spongy stems, sometimes 12 feet in length, and broadly ovate, acuminate, leathery leaves. The fruit is about the size of a pea, of a bright-red colour when ripe, not crowded on the spike. In cultivation the pepper plant is supported by poles, or by small trees planted for the purpose, as it loves a certain degree of shade, and different kinds of trees are often planted for this purpose in India. It is propagated by cuttings or suckers, comes into bearing in three or four years after it is planted, and yields two crops annually for about twelve years. When any of the 'berries' of a spike begin to change from green to red all are gathered, as when more fully ripe they are less pungent, besides being apt to drop off. They are spread on mats to dry in the sun, and separated from the spikes by rubbing with the hands or by treading with the feet, after which they are cleaned by winnowing. The Black Pepper of commerce consists of the berries thus dried, which become wrinkled and black; White Pepper is the seed freed from the skin and fleshy part of the fruit, to effect which the dried fruit is soaked in water and then rubbed. White pepper thus prepared is of a whitish-gray colour, but not unfrequently undergoes a bleaching by chlorine, which improves its appearance at the expense of its quality. Black pepper is much more pungent than white pepper, the essential constituents of the spice being more abundant in the outer parts of the fruit than in the seed. Pepper depends for its properties chiefly on an acrid resin and volatile oil; it contains also a crystalline substance called *Piperin*. The fruit of *Piper trioicum*, a species very similar to the Common Pepper, is more pungent; and it is cultivated in some parts of India. The fruit of other species of Piperaceæ is used as pepper in their native countries. The fruit of *Piper longum* or *Chavica Roxburghii* yields the Long Pepper of commerce. They have woody climbing stems, solitary spikes opposite to the leaves, dioecious flowers, and the fruits so close together on the spikes as in ripening to become a compact mass. The spikes are gathered when unripe, and dried in the sun. They are used in pickling and for culinary purposes, also in medicine for the same purposes as common pepper. They are generally reputed to be more pungent than common pepper. *C. Roxburghii* is cultivated in eastern India, Ceylon, and Java. The root and thickest part of its stem are extensively used in India as a stimulant medicine.

Black Pepper (*Piper nigrum*).

Pepper acts on the skin as a rubefacient and vesicant, and is often used for this purpose in a powdered state, moistened with some kind of alcoholic spirit. It is also employed as a local stimulant in relaxation of the uvula, and is applied in the form of an ointment to ringworm. Taken into the stomach in small quantities it is a pleasant stimulant, but in large doses it produces great pain and irritation. The quantity used, however, by the natives of hot climates much exceeds anything known among Europeans, and the effects are evidently beneficial rather than injurious. The chief use of pepper is as a spice and condiment.

Pepper was known to the ancients; Hippocrates employed it as a medicine, and Pliny expresses his surprise that it should have come into general use, considering its want of flavour. In the middle ages pepper was one of the most costly spices, and in the 13th century a few pounds of it were reckoned a princely present. The quantity now imported into Europe is immense. The average annual imports into the United Kingdom are about 29 million lb., of which about 7 million lb. are taken for consumption; the quantity imported into the United States is of course even larger. Malabar black pepper is considered the best kind, and the Tellicherry and Penang the finest varieties of the white.

The name pepper is popularly given to substances possessing a pungency resembling that of pepper, although produced by very different plants. Thus, Cayenne Pepper is the produce of species of Capsicum (q.v.), of the natural order Solanaceæ; Jamaica Pepper, or Pimento (q.v.), of species of Eugenia, of the natural order Myrtaceæ; and Guinea Pepper (q.v.), or Maleguetta Pepper, is *Amomum*, Ethiopian Pepper *Xylopia Æthiopica*, and Benin Pepper *Cubeba Clusii*.

Pepper, John Henry, chemist and mechanical inventor, was born in Westminster on 17th June 1821, and in 1848 was appointed analytical chemist at the Royal Polytechnic, and has written several handbooks of popular science. But he is best known as the improver and exhibitor of 'Pepper's Ghost,' in its earliest form the invention of Henry Dircks (q.v.), a device for associating on the same stage living persons and phantoms to act together. The phantom is produced by a large sheet of unsilvered glass on the stage, practically invisible to the spectators, which reflects to them, along with a visible actor or actors, the appearance of another actor on an understage, who is himself invisible. Pepper travelled with this show in America and Australia, and became public analyst in Brisbane, Queensland.

Peppercorn Rent, a nominal rent of one peppercorn a year, to be paid on demand; an acknowledgment of tenancy when lands or houses are let virtually free of rent.

Peppermint. See Mint.

Pepper-pot, a celebrated West Indian dish, of which Casareep (q.v.) is a principal ingredient; and along with it flesh or dried fish, vegetables,

chiefly the unripe pods of the ochro (a Hibiscus, q.v.), and chillies (see CAPSICUM).

Pepper-root (*Dentaria diphylla*), a perennial herbaceous plant, of the natural order Cruciferæ, a native of North America, with pairs of ternate leaves, and racemes of white flowers; the root of which has a pungent mustard-like taste, and is used as a condiment.

Pepsin has been already discussed (in the article DIGESTION) as one of the essential constituents of the gastric juice. Various modes of extracting it from the walls of the stomach of the calf, sheep, and pig have been proposed by different chemists. It has not been satisfactorily isolated, and its chemical constitution is unknown. 'At present the manifestation of peptic powers is our only test of the presence of pepsin' (M. Foster). This substance, either in powder or in solution, has been employed of late years to a considerable extent in medical practice, in cases of disorders of digestion due to deficient or imperfect secretion of gastric juice, and of convalescence from typhoid and other debilitating fevers. It is an ingredient in most of the digestive preparations now in the market.

Peptones. See DIGESTION, Vol. III. p. 819.

Pepys, SAMUEL, the celebrated diarist, son of John and Margaret Pepys, was born on February 23, 1632–33. He was a member of a junior branch of an old and widely-spread family in the eastern counties, but there was little property in the possession of this branch, and Samuel's father for a time followed the business of a tailor in the city of London. It is not known whether the diarist was born at Brampton, a village near Huntingdon, where there was a small property belonging to his father's family, or in London. We do know, however, that he went to school at Huntingdon before entering St Paul's School, and that he remained at the latter until he was seventeen years of age. On March 5, 1650–51, he first put on his gown as a scholar at Magdalene College, Cambridge. On the 1st December 1655, very soon after leaving college, he was married to Elizabeth St Michel, a beautiful but portionless girl of fifteen. Sir Edward Montagu (afterwards Earl of Sandwich), whose mother was a Pepys, gave a helping hand to the imprudent couple, and allowed them to live in his house. As Samuel does not appear to have owed much to his father, it seems probable that Montagu acted as a patron at a still earlier period of his life. At all events his true start was entirely due to this patron, for whom Pepys always expressed the most unbounded attachment. Pepys's real life begins for us on the 1st January 1659–60, when the *Diary* was commenced. His appointment to the clerkship of the Acts of the Navy in 1660 was distinctly a job, for he knew nothing of the work of the navy when he undertook the office, but it was a job that amply justified itself, for his intelligence and industry were so great that he soon became master of the work of his office, and as Clerk of the Acts, and subsequently as Secretary to the Admiralty, he was one of the most distinguished officials in naval affairs that England has ever possessed. At the Revolution his career was closed, but until the end of his life he was still looked upon as the Nestor of navy affairs, to be consulted upon matters of particular importance, and his name is still held in honour at the Admiralty. It is not, however, as an official that the fame of Pepys still lives, but as the writer of a *Diary* which is unique in the literature of the world. This work has thrown the most unexpected light upon the history and manners of his day, while at the same time it presents a most remarkable psychological study. Never before had man written down his inmost feelings with so little disguise. Hence Pepys's character has suffered while his fame has spread. Passing thoughts which had but little real influence upon his actions were set down by him, and they have given a wrong impression of the man to numerous readers.

Pepys's life was prosperous, for he made money and held high offices. He was twice Master of the Trinity House, first in 1676 and a second time in 1685, Master of the Clothworkers Company in 1677, and President of the Royal Society (1684–86). But he was not without his troubles. At the period of the supposed Popish Plot in 1679 he was committed to the Tower, and in 1690 he was placed in Gatehouse at Westminster for a few days; and at his death the crown was indebted to him to the extent of £28,000, a sum which was never paid. Early in life Pepys was successfully cut for the stone, and for many years he enjoyed good health, but before his death, on the 26th May 1703, the wound broke out afresh. The *Diary* was discontinued on 29th May 1669, and we must ever regret that it was not continued to a later period. The shorthand MS. was deciphered by the Rev. J. Smith and first published in 1825 under the editorship of Lord Braybrooke. Although much original matter has been added to various editions, particularly in that of the Rev. Mynors Bright (1875), the *Diary* had never been printed in its entirety up to 1891, when a new edition of the whole was in preparation. Besides the *Diary* Pepys wrote nothing of importance but his *Memoires relating to the State of the Royal Navy*, published in 1690. Pepys was essentially a collector, and he never saw a curious or uncommon object without wishing to possess it. His library, bequeathed to Magdalene College, Cambridge, still remains in the exact condition in which he left it. In the room containing that library and among his books and papers we the better understand that method, diligence, and general intelligence which is exhibited in the *Diary*, and which, united with the power of carrying out his views, helped to consolidate the British navy.

See *Memoirs of Samuel Pepys, Esq., Comprising his Diary from 1659 to 1669*, edited by Lord Braybrooke (2 vols. 1825); *Diary and Correspondence*, by Rev. Mynors Bright (6 vols. 1875); *Life, Journal, and Correspondence of Samuel Pepys*, by Rev. John Smith (2 vols. 1841); and *Samuel Pepys and the World he lived in* (1880) and the edition of the Diary (8 vols. 1893–96), by the present writer.

Pequots, or PEQUODS, a tribe of American Indians, a branch of the Mohicans, were warlike and powerful in the country round the Thames River when Connecticut was first settled, and made treaties with the Dutch and English. Hostilities, however, broke out in 1637, and the tribe was cut to pieces and scattered; yet a few descendants may be found at Green Bay, Wisconsin.

Pera, a suburb of Constantinople (q.v.).

Peræa (Gr., 'the country beyond'), a term applied to many districts beyond a river or sea; most frequently to great part of Palestine (q.v.) beyond the Jordan.

Perak, a Malay state on the west side of the peninsula of Malacca, under the protection of Britain since 1874. Estimated area, 7950 sq. m. The interior ranges up to 8000 feet. The soil is fertile, and for the most part covered with luxuriant vegetation. Elephants, leopards, huge snakes, and deer swarm in the forests of the interior. The soil produces rice, sugar, tobacco, coffee, tea, vanilla, and spices. But the principal production of the state is tin; the mines, worked chiefly by Chinamen, yielded 2060 tons in 1876 and 23,866 tons in 1895. Lead also exists in great quantity. Pop.,

mostly Malays and Chinese, increased from 55,880 in 1879 to 214,254 in 1891. The capital is Kwala Kansar. Taiping and Kinta are the principal tin-mining towns. There are 70 miles of railway. The British have made many miles of good roads since they began to govern the country. The murder of J. W. Birch, the first British resident, in 1875 necessitated a punitive military expedition in 1876. The state is now in a highly prosperous condition, exporting to the annual value of $15,000,000, and importing to $10,000,000. See books by M'Nair (1877) and Swettenham (1894).

Perambulation. See BOUNDS (BEATING THE).

Perameles. See BANDICOOT.

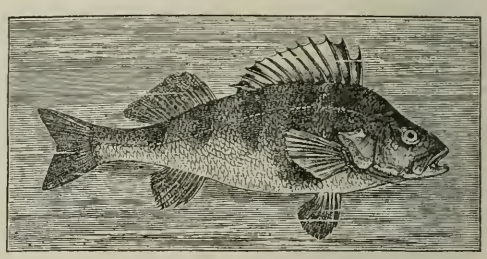
Perception, in philosophical usage, may mean internal perception, the apprehension of any modification of consciousness; but it usually refers to external perception, the recognition of an external object by means of the senses—something more than sensation, and including an element of judgment or the comparing power.

Two great disputes connect themselves with perception, both raised into prominence by Berkeley. The first is the origin of our judgments of the distances and real magnitudes of visible bodies; Berkeley maintaining, in opposition to the common opinion on this subject, that these were learned by experience, and not known by the mere act of vision (see VISION). The second question relates to the grounds we have for asserting the existence of an external and material world. See BERKELEY, KANT, REID; also PSYCHOLOGY, PHILOSOPHY.

Perceval, SPENCER, English minister, was the second son of the second Earl of Egmont, and was born in London, November 1, 1762. He was educated at Harrow and Trinity College, Cambridge, and was called to the bar at Lincoln's Inn in 1786. He soon obtained a reputation as a diligent lawyer, and in 1796 he entered parliament for Northampton, and became a strong supporter of Pitt. In the Addington administration he was made Solicitor-general in 1801 and Attorney-general in 1802, and in the Portland administration of 1807 he became Chancellor of the Exchequer, and was even then the real head of the government, being much trusted by George III. for his steadfast opposition to the Catholic claims. On the death of the Duke of Portland in 1809 Perceval became premier also, and retained office till his tragic death, 11th May 1812, when he was shot dead entering the lobby of the House of Commons, about five in the afternoon, by a Liverpool broker named Bellingham, whose losses had turned his head. Perceval's death was rather a private than a public calamity. He was a man of spotless integrity in his public and private character, but, though an effective parliamentary debater, his abilities were only moderate and his views were narrow.

Perch (*Perca*), a genus of spiny-finned or acanthopterous fishes, well represented by the Fresh-water Perch (*P. fluviatilis*). The members of the large family (Percidæ) to which the perch belongs are carnivorous fishes, frequenting the fresh waters and coasts of temperate and tropical regions. The body is somewhat compressed; the spinous dorsal fin is well developed; the ventral fins are thoracic in position; the teeth are simple and conical; there are no barbels. These characters are possessed by many perch-like fishes, some of which are discussed in separate articles—e.g. the Bass (Labrax); the Perch (Lates) of the Nile, Ganges, &c.; the Pike-perch (Lucioperca); the Sea-perch (Serranus); the Murray Cod and Hapuku (Oligorus); the Growler (Grystes), &c. Of American Percidæ the 'glass-eye' or 'yellow pike' (*Stizostedion vitreum*) is largest and most important, while the dwarf-perches or darters (Microperea, Percina, &c.) are among the minutest fishes, *Microperea punctulata* measuring only an inch and a half.

The fresh-water perch is widely distributed in lakes, ponds, and rivers in Europe, North Asia, and North America, and is common in many parts of Britain. It is of a greenish-brown colour above and golden yellow on the under parts, with six or



Perch (*Perca fluviatilis*).

seven indistinct dark bands on the back. In length it measures about 18 inches, and its height is about a third of this. It sometimes weighs from three to five pounds, and a prize of nine pounds has been recorded. Among its characteristics may be noted the small villiform backward-turned teeth, their presence on the palatines and vomer, their absence from the tongue, the two dorsal fins, of which the first has thirteen or fourteen spines, and the small scales on the body. The perch loves still waters, and thrives well in ponds, at the cost, however, of smaller fishes. It also feeds on insects, worms, &c. It can endure removal from the water for a considerable time. The eggs are laid in spring, and are attached in long viscid strings to water-weeds. The number of eggs in one spawn may exceed a million. As an edible fish the perch has a good reputation, eating best with lemon-juice and cayenne-pepper, but the American variety is less esteemed. Of species distinct from *P. fluviatilis* little is known.—The so-called Climbing Perch (q.v.) is separately treated.

Perch. See ROD.

Percival, JAMES GATES, an American poet, was born at Kensington, Connecticut, 15th September 1795, graduated at Yale in 1815, at the head of his class, and afterwards studied botany and medicine. But his heart was not in herbs and physic, and although he practised—or rather advertised his willingness to practise—both in Kensington and in Charleston, S.C., very few professional calls dragged him from his favourite studies. His poems *Prometheus* and *Clio* appeared at Charleston in 1822. Two years later he filled for a few months the chair of Chemistry at West Point; but he found the duties heavy and irksome, and took himself to Boston, and then to New Haven. There the third part of *Clio* was published (1827). Percival afterwards divided his attention between his verses and geology, and as he grew older he gave more and more of his time to the new love, the visible results being Reports on the Geology of Connecticut (1842) and of Wisconsin (1855). These are valuable but very dry, and in delicious contrast to his poems, which flow freely and with volume, and on whose fluent, half-careless lines their author's learning is borne as easily as trees on a river in flood. His *Dream of a Day* appeared in 1843, and occasional lyrics for a long time after. He was appointed geologist of Wisconsin in 1854, and died there at Hazel Green, on 2d May 1856. His collected works were published in 1859, his *Life and Letters*, by J. H. Ward, in 1866.

Percussion, in Medicine, is the method of eliciting sounds by tapping or gently striking the surface of the body; its object being to determine by the nature of the sound the comparative density of the subjacent parts. This means of diagnosis was first employed by Auenbrugger in the middle of the 18th century, and it was afterwards adopted by Corvisart in the investigation of heart diseases; but its value was not fully appreciated till Laennec made the diseases of the chest his peculiar study; and since his time its application and various uses have been extended by the labours of Piorry, Hughes Bennett, and other physicians.

Percussion is chiefly employed in the diagnosis of diseases of the lungs, heart, and abdominal organs. It may be *direct* (or, as some writers term it, *immediate*), or it may be *mediate*. In the former case, the part to be examined is struck with the ends of the first three fingers set close together on the same level, or with a small hammer tipped with india-rubber; while in the latter, which is now almost universally adopted, a flat body is placed upon the chest, or other part to be examined, and is then struck by the fingers or hammer. The flat intervening body is termed a *Plexímeter* (from the Gr. *plexis*, 'a blow,' and *metron*, 'a measure'). The instrument usually sold as a plexímeter is a flat oval piece of ivory, but the left index or middle finger of the physician, with its flat surface fitted accurately to the part to be examined, acts equally well. The force of the stroke on the plexímeter—whether the stroke be made with the fingers or the hammer—must vary according as it is desired to elicit the sound from a superficial or a deep-seated part. The surface to be percussed should be exposed, or, at most, only covered with one layer of clothing; and the blow should fall perpendicularly on the plexímeter. When percussion is made over a considerable cavity filled with air—as the stomach or intestines—a hollow, drum-like, or (as it is usually termed by medical writers) a *tympanitic* sound is produced. When any part of the surface of the chest is struck below which there is a considerable depth of healthy lung-tissue, consisting of small cells filled with air, a clear sound, less loud and hollow than the tympanitic sound, and termed the *pulmonary percussion note*, depending partly on the vibrations of air in the lung-cells, and partly on the vibrations of the walls of the chest, is evolved. When the subjacent substance is solid (as the heart, liver, or spleen) or fluid (as when there is effusion into a closed sac) the sound is *dull* in proportion to the density and want of elasticity of the part struck. Important information is also gained by attending to the varying degree of resistance experienced by the fingers during percussion over different parts of the surface. The first thing that must be acquired in order to make percussion useful in the diagnosis of disease is an accurate knowledge of the sounds elicited from the different parts in their normal condition. When, for example, the healthy pulmonary percussion note is known, increased resonance of the walls of the chest will indicate a dilatation of the air-cells (or Pulmonary Emphysema), while various degrees of dullness will afford evidence of such morbid changes as the effusion of fluid into the pleura (Hydrothorax), or inflammatory solidification of the lung-tissue (the Hepatisation of Pneumonia), or tubercular deposition. The use of percussion in relation to diagnosis is further shown in the articles PERICARDITIS and PLEURISY. Diagnosis by Auscultation (q.v.), directly and by means of the Stethoscope (q.v.), is often used in connection with percussion.

Percussion Caps are small copper cylinders, closed at one end, for conveniently holding the detonating powder which is exploded by the act of percussion in percussion-arms. See FULMINATES; also FIREARMS, Vol. IV. p. 639.

Percussion, CENTRE OF. See CENTRE OF PERCUSSION.

Percy, a noble northern family, famous in the history of England for five hundred years. Its founder, William de Percy, came with the Conqueror to England, and was rewarded with lands in Hampshire, Lincolnshire, and Yorkshire—among the last being Topcliffe and Spofforth, long the chief seats of the house. The male descendants became extinct with the death of the third baron, and the representation of the house devolved upon his daughter Agnes, who married Josceline of Louvain, brother-in-law of King Henry I., on the condition that he assumed the name of Percy. Their youngest son, Richard de Percy, then head of the family, was one of the chief barons who extorted Magna Charta from King John, and the ninth feudal lord, Henry de Percy, gave much aid to Edward I. in the subjugation of Scotland, and was made governor of Galloway. The latter was driven out of Turnberry Castle by Robert Bruce, and was rewarded by Edward II. with the empty honour of Bruce's forfeited earldom of Carrick, and the governorship of the castles of Bamborough and Scarborough. In 1309 he obtained by purchase from Bishop Antony Bek the barony of Alnwick, the chief seat of the family ever since. His son, Henry de Percy, defeated and captured King David II. of Scotland at the battle of Neville's Cross (1346); his grandson fought at Crécy; his great-grandson, the fourth Lord Percy of Alnwick, was marshal of England at the coronation of Richard II., and was created the same day Earl of Northumberland. Henry, eldest son of the last, was the famous Hotspur whom the dead Douglas defeated at Otterburn (1388), and who himself fell at Shrewsbury (1403) fighting against King Henry IV. His brother, Thomas Percy, Earl of Worcester, was executed immediately after the battle. Their father, who had turned against Richard II., and helped Henry of Lancaster to the throne, was dissatisfied with Henry's gratitude, and with his sons plotted the insurrection which ended in Shrewsbury fight. Later he joined Archbishop Scroope's plot, and fell at Bramham Moor (1408), when his honours were forfeited on attainder, but restored in 1414 to his grandson Henry, the second earl, from which day the Lancastrian loyalty of the family never wavered. Henry became High Constable of England, and fell in the first battle of St Albans (1455). His son Henry, the third earl, fell at Towton (1461), and it was his brother, Sir Ralph Percy, who comforted himself as he lay bleeding to death on Hedgley Moor (1464), that he had 'saved the bird in his bosom.' The title and estates were now given to Lord Montagu, a brother of Warwick, the king-maker, but in 1469 Henry, the son of the third earl, subscribed an oath of allegiance to Edward IV., and was restored. He was murdered at his Yorkshire house of Cocklodge, in 1489, in an outburst of popular fury against an extortionate subsidy of Henry VII. The sixth earl, Henry-Algernon, in youth had been the lover of Anne Boleyn, and was forced against his will to marry a daughter of the Earl of Shrewsbury. He died childless in 1537, and, as his brother Sir Thomas Percy had been attainted and executed for his share in the Pilgrimage of Grace, the title and honours were forfeited, and the title of Duke of Northumberland was conferred by Edward VI. upon John Dudley, Earl of Warwick, who in turn was attainted and executed under Mary in 1553. That queen in 1557 granted the earldom to Thomas

Percy, son of the attainted Sir Thomas Percy. A devoted Catholic, he took part in the Rising of the North, and was beheaded at York in 1572. His brother Henry succeeded as eighth earl. He became involved in Throgmorton's conspiracy in favour of Mary Stuart, and was committed to the Tower, where he was found dead in bed, with a pistol beside him, whether through suicide or murder, 21st June 1585. His son, the ninth earl, was imprisoned for fifteen years in the Tower, and fined £30,000 on a baseless suspicion of being privy to the Gunpowder Plot. He was followed by his son, the tenth earl, who fought on the parliamentary side in the Civil War, and was succeeded by his son Josceline, the eleventh earl, with whose death in 1670 the male line of the family became extinct. Charles II. created in 1674 his third bastard by the Duchess of Cleveland, Earl, and afterwards Duke, of Northumberland, but the titles expired on his dying childless in 1716. The eleventh earl's only surviving child and heiress, in her own right Baroness Percy, married Charles Seymour, Duke of Somerset, and became the mother of Algernon, Duke of Somerset, who was created in 1749 Baron Warkworth and Earl of Northumberland, with remainder to his son-in-law, Sir Hugh Smithson, fourth Baronet, of Stanwick in Yorkshire. Sir Hugh succeeded to the earldom in 1750, assuming the surname and arms of Percy, and was created in 1766 Earl Percy and Duke of Northumberland. The sixth duke succeeded in 1867.

See books cited under NORTHUMBERLAND, and E. Barrington de Fonblanque's *Annals of the House of Percy* (privately printed, 2 vols. 1887).

Percy, THOMAS, editor of the famous *Reliques of Ancient English Poetry*, was born a grocer's son at Bridgnorth in Shropshire, April 13, 1729. He was educated at the grammar-school there; in 1746 entered Christ Church, Oxford; and in 1753 was presented by his college to the sequestered vicarage of Easton Maudit, Northamptonshire, where he lived for twenty-five years. In 1756 he married happily, and three years after received also the adjacent rectory of Wilby. His leisure soon yielded fruit in *Hau Kiou Chooan* (4 vols. 1761), a Chinese novel translated from the Portuguese, and *Miscellaneous Pieces relating to the Chinese* (2 vols. 1762), as well as anonymously in *Five Pieces of Runic Poetry translated from Icelandic* (1763), prompted by the success of Macpherson, and *A New Translation of the Song of Solomon from the Hebrew* (1764). In the summer of 1764 Dr Johnson paid him a long visit at Easton Maudit. In later days they sometimes quarrelled, but continued to retain a high regard for each other. 'A man out of whose company I never go without having learned something'—so Johnson described him to Boswell. 'I am sure that he vexes me sometimes, but I am afraid it is by making me feel my own ignorance.' In the February of the following year (1765) Percy published in 3 vols. the *Reliques of Ancient English Poetry* (4th ed. 1794; an excellent edition by H. B. Wheatley, 3 vols. 1886). He had long been engaged in collecting old ballads from every quarter, and a large folio MS. of ballads had fallen accidentally into his hands, having been found 'lying dirty on the floor under a Bureau in the Parlour' of his friend Humphrey Pitt of Shiffnal, in Shropshire, 'being used by the maids to light the fire.' This he claimed as the original of his work, but of the 176 pieces in the first edition actually only 45 were taken from the folio MS.; while almost all those actually from it were so touched up and tricked out in false ornament and conventional 18th-century poetic diction as often to bear but little likeness to their originals. For example, the 39 lines of the 'Child of Ell' have been puffed out to 200 in Percy's version, nor do even all the 39 originals themselves appear. Again, the 'Heir of Lin' has swollen from 125 lines to 216, and these, moreover, polished to death. The antiquary Ritson, in his 'Observations on the Ancient English Minstrels' prefixed to his *Ancient Songs from Henry III. to the Revolution* (1790), attacked Percy with characteristic acrimony, denied the very existence of the folio MS., and denounced the work as an impudent forgery, and that the worse because by a clergyman. Percy exhibited the MS. in Pall Mall, and had his portrait painted by Sir Joshua Reynolds holding it in his hand. For over a hundred years it lay hid in Ecton Hall, jealously guarded from almost all eyes, until at length Mr Furnivall, instigated by Professor Child, succeeded in getting it printed (3 vols. 1867–68; those deservedly marked by the bishop 'loose and humorous' being printed separately), with Introductions by Professor Hales and himself. The MS. was 15½ inches long by 5½ wide and about 2 inches thick, and was written in a Caroline hand.

The publication of Percy's *Reliques* was first suggested to him by Shenstone. The work was dedicated to the Countess of Northumberland, and the author was soon rewarded by being made chaplain to her husband, the first duke of the present creation, while he also succeeded in persuading himself that he was a scion of the noble house of Percy. In 1769 he became chaplain to George III., and next year he took his degree of D.D. at Cambridge, and published his translation of the *Northern Antiquities* of the Swiss historian Paul Henri Mallet (1730–1807). About 1771 his wife was appointed nurse to the Prince Edward, afterwards father of Queen Victoria; it was to her, before their marriage, that Percy addressed the famous ballad, 'O Nancy wilt thou go with me?' first printed in 1758, and happily set to music by an Irishman, Thomas Carter (*c.* 1735–1804). In 1771 Percy wrote also his pleasing ballad the 'Hermit of Warkworth.' In 1778 he was appointed to the deanery of Carlisle, in 1782 to be Bishop of Dromore, with £2000 a year. His only son died in 1783; his wife in 1806; he himself, after a few years of blindness, 30th September 1811—the only survivor of the original members of Dr Johnson's famous Literary Club. He left two daughters, and was buried in the transept which he himself had added to Dromore Cathedral.

For the literary influence of the *Reliques*, see the article BALLAD. A good Life by the Rev. J. Pickford is prefixed to vol. i. of Hales and Furnivall's reprint. Many of his letters are given in vol. viii. of J. B. Nichol's *Illustrations of the Literary History of the 18th Century*. His name was assumed by the Percy Society (94 issues, 1840–52).

Percy Anecdotes, a collection of extraordinary popularity, published in monthly parts (1820–23) by 'Sholto and Reuben Percy, Brothers of the Benedictine Monastery of Mount Benger.' Their real names were Thomas Byerley (died 1826), first editor of the *Mirror*, and Joseph Clinton Robertson (died 1852), projector and editor of the *Mechanics' Magazine;* the work owed its name to the Percy Coffee-house in Rathbone Place, their usual place of meeting during its progress. An edition was prepared by John Timbs (1868).

Peregrine Falcon. See FALCON.

Pereira, JONATHAN, pharmacologist, was born at Shoreditch, London, 22d May 1804, and was successively lecturer on chemistry and physician to the London Hospital (1841). Elected a Fellow of the College of Physicians in 1845, he acted as examiner in Materia Medica and Pharmacy from the establishment of the London University till his death, 20th January 1853. His books were *Elements of Materia Medica* (1839–40), and treatises on *Diet* and on *Polarised Light* (1843). See *Memoir* (1853).

Perekop, ISTHMUS OF, in South Russia, connecting the peninsula of the Crimea (q.v.) with the mainland of European Russia. For the dimensions and course of the ship-canal through the isthmus (projected in 1888, but not begun in 1898), see CANAL, Vol. II. p. 701. In the north of the isthmus is the small town of Perekop; pop. 5000.

Père-la-Chaise. See LACHAISE; and for the cemetery, PARIS, p. 764.

Perennial, in Botany, a term employed in contradistinction to Annual (q.v.) and Biennial (q.v.), to designate plants which subsist for a number of years. Some plants, however, which are annual in cold climates are perennial in warmer regions. The term perennial is in general applied only to herbaceous plants, and indicates a property only of their roots, the stems of most of them dying at the end of each summer. Perennial herbaceous plants, like shrubs and trees, are capable of producing flowers and fruit time after time, in which they differ from annual and biennial plants, which are fruitful only once. Those plants which are capable of being propagated by cloves, offset bulbs, or tubers are all perennial. Thus, the potato is a perennial plant, although the crop is planted in spring and reaped in autumn, like that of corn, whilst all the corn plants are annuals. There is great diversity in the duration of life of perennial plants.

Pereslavl, a town of Russia, 96 miles NE. of Moscow by rail. It has a 12th-century cathedral, cotton-manufactures, and lake-fisheries. Pop. 7466.

Pérez, ANTONIO, minister of Philip II. of Spain, was born in Aragon in 1539. His reputed father was an ecclesiastic who was secretary to Charles V. and Philip II., and he himself was appointed to this office when only twenty-five years of age, and acquired the entire confidence of the king. Don John of Austria having sent his confidant, Juan de Escovedo, to Spain, to solicit aid against the party of Orange, and Escovedo having rendered himself an object of suspicion to the king as an abettor of Don John's ambitious schemes, Philip resolved to put him out of the way by murder, and entrusted Perez with the accomplishment of this design, which Perez accomplished accordingly, 31st March 1578. The family of Escovedo denounced Perez as the murderer, and all his enemies joined against him. The king at first sought to shield him; but in July 1581 he was arrested, and by torture forced to confess. He succeeded, however, in making his escape to Aragon, where he put himself under protection of its fueros, which secured a trial in open court. The king, charging him with heresy, now applied for aid in May 1591 to the Inquisition, and the Aragonese court delivered him up to its agents; but the people rose in tumult and liberated him. This happened repeatedly; and at last, in September 1591, Philip II. entered Aragon with an army powerful enough to subdue all opposition, and abolished the old constitutional privileges of the country. Perez, however, made his escape, was condemned in Spain as a heretic, but was treated with great kindness in Paris and in London, where he was the intimate of Bacon and the Earl of Essex. He spent the later years of his life in Paris, and died there, 3d November 1611, in great poverty. Perez wrote *Relaciones* (1598), which some recent writers have regarded as lying fabrications.

See Mignet's monograph (5th ed. 1881); Morel-Fatio, *L'Espagne au XVI. et au XVII. Siècle* (1878); also Froude in *The Spanish Story of the Armada* (1892); and works cited at PHILIP II.

Perfectibility, or PERFECTIONISM, the doctrine that man in a state of grace may attain to perfection in this life. Catholics hold that no one, not even the most holy, can avoid sin altogether except by a special privilege of God, as in the case of the Blessed Virgin; the justified do not, however, commit mortal, but venial sins (see SIN). In various points Franciscans, Jesuits, and Molinists approach to a doctrine of perfection denied by Dominicans and Jansenists. Among Protestants, Wesleyan Methodists believe in the possibility of a *Christian perfection* attainable in this life. It is not a perfection of *justification*, but a perfection of *sanctification;* which John Wesley, in a sermon on Christian Perfection, from the text Heb. vi. 1, 'Let us go on to perfection,' earnestly contends for as attainable in this life by believers, by arguments founded chiefly on the commandments and promises of Scripture concerning sanctification; guarding his doctrine, however, by saying that it is neither an *angelic* nor an *Adamic* perfection, and does not exclude ignorance and error of judgment, with consequent wrong affections, such as 'needless fear or ill-grounded hope, unreasonable love, or unreasonable aversion.' He admits, also, that even in this sense it is a rare attainment. The Friends profess that the justified may be 'free from actual sinning and transgression of the law of God, and in that respect perfect. Yet doth this perfection admit of a growth; and there remaineth a possibility of sinning where the mind doth not most diligently and watchfully attend unto the Lord.' Other schools also hold similar views; but most Protestants repudiate the doctrine of Perfectibility. The general belief of Protestant Christians is that those who have professed a belief in their own perfectibility were merely more self-complacent and less sensible of their own corruptions than is usual, and that the commands and promises concerning sanctification are all susceptible of an explanation consistent with remaining corruption in believers, and a need of further sanctification, or a continued going on unto perfection whilst this life endures.

Perfection, COUNSELS OF. See SUPEREROGATION.

Perfectionists, also called BIBLE COMMUNISTS and FREE-LOVERS, a small American sect, founded by John Humphrey Noyes, who was born at Brattleboro, Vermont, 6th September 1811, graduated at Dartmouth in 1830, then studied law, and afterwards theology at Andover and Yale. While a theological student, he experienced a second conversion, discovered that the prevailing theology was wholly wrong, and lost his license to preach. He held that the gospel if accepted secures freedom from sin; that God has a dual body (male and female); that the author of evil is uncreated, but not God; and that communion with Christ not merely saves from sinning, but from disease and death. He now founded a 'Perfectionist' church at Putney, Vermont. He and his converts, men and women, with their children, put their property into a common stock; they gave up the use of prayer, all religious service, and the observance of the Sabbath; those who were married renounced their marriage ties, and a 'complex marriage' was established between all the males and all the females of the 'Family.' Having dispensed with law, he set up public opinion as a controlling power in its stead; and free criticism of one another by the members of the society became an important feature of his system. In 1848, after not a few difficulties, the community removed to a new home in the sequestered district of Oneida, in the state of New York, and soon numbered some 300 members, living in strict order and with much outward comfort on thoroughly communistic principles—the community of women and of children being an

outstanding feature carefully regulated by the 'mutual criticism' of the family. In 1880, however, the pressure of outside opinion forced the family to modify their peculiar principles; marriage and the ordinary family relationship was introduced; communism of property gave way to limited liability joint-stock, each member having a separate share represented by so much stock in the Oneida Community, Limited. Various co-operative institutions were also established. The headquarters are at Kenwood, New York, and works have been started also at Niagara Falls, Ontario. Noyes, who assisted in elaborating the new constitution, died at Niagara Falls, 13th April 1886.

See works by Noyes, *The Second Coming of Christ, Salvation from Sin the End of Faith*, and *History of American Socialism;* the periodicals conducted by him (nearly 40 vols. 1834-80; in British Museum); Hepworth Dixon's *New America*, &c.; Charles Nordhoff, *Communistic Societies of the United States* (1875).

Perfumery. Perfumes are of two distinct classes—those derived from plants and those which are of animal origin.

Vegetable Perfumes.—The most ancient of the so-called primary odoriferous bodies are the so-called gum-resins which exude naturally from the trees which yield them, or from wounds accidental or purposely inflicted to increase the yield. The most important are benzoin, myrrh, opoponax, tolu, Peru, and storax. Gum-resins form the chief ingredients in 'Incense' (q.v.) and Pastilles (q.v.).

A second group is that large class of perfumes which are procured by distillation, and are mostly fluid bodies, and are termed Volatile Oils, Essential Oils, or Ottos—formerly Quintessences (see OILS). As soon as the Greeks and the Romans learned the use of the still, which was an invention imported by them from Egypt, they quickly adapted it to the separation of the odorous principle from the numerous fragrant plants indigenous to Greece and Italy. Long before that time, however, fragrant waters were in use in Arabia. Odour-bearing plants contain the fragrant principle in minute glands or sacs; these are found sometimes in the rind of the fruit, as the lemon and orange; in others it is in the leaves, as sage, mint, and thyme; in wood, as rosewood and sandalwood; in the bark, as cassia and cinnamon; in seeds, as caraway and nutmeg; in yet others in the petals, as in rose, lavender, or Ihlang-Ylang. The odour principle of orris is a solid resembling cocoa-butter, and is contained in what is really the rhizome of *Iris florentina*, though technically called orris-root. These glands or bags of fragrance may be plainly seen in a thin-cut stratum of orange-peel; so also in a bay leaf, if it be held up to the sunlight, all the oil-cells may be seen like specks. All the fragrance-bearing substances yield by distillation an essential oil peculiar to each; thus is procured oil of patchouli from the leaves of the patchouli plant, *Pogostemon patchouli*, a native of Burma; oil of caraway, from the caraway-seed; oil of geranium, from the leaves of the *Pelargonium roseum;* oil of lemon, from lemon-peel, *Citrus limonis;* and a hundred of others of infinite variety.

All the various essential oils or ottos are very slightly soluble in water, so that in the process of distillation the water which comes over is always fragrant. Thus, elder-water, rose-water, orange-water, dill-water are, as it were, the residue of the distillation for obtaining the several ottos. The process of Distillation (q.v.) is very simple: the fragrant part of the plant is put into the still and covered with water, and when the water is made to boil the ottos rise along with the steam, are condensed with it in the pipe, and remain floating on the water, from which they are easily separated by decanting. In this way 100 lb. of orange, lemon, or bergamot fruit peel will yield about 10 oz. of the fragrant oil; 100 lb. of cedar-wood will give about 15 oz. of oil of cedar; 100 lb. of nutmeg will yield 60 to 70 oz. of oil of nutmeg; 100 lb. of geranium leaves will yield 2 oz. of oil.

Every fragrant substance varies in yield of essential oil. The variety of essential oils is endless; but there is a certain relationship among odours as among tints. The lemon-like odours are the most numerous, such as verbena, lemon, bergamot, orange, citron, citronella; then the almond-like odours, such as heliotrope, vanilla, violet; then spice odours, cloves, cinnamon, cassia. The whole may be classified into twelve well-defined groups. All these ottos are very soluble in alcohol, in fat, butter, and fixed oils. They also mix with soap, snuff, starch, sugar, chalk, and other bodies, to which they impart their fragrance.

The principal consumption of the cheaper sorts of fragrant ottos is for scenting Soaps (q.v.), most of which are perfumed while in a melted state with the several ottos or mixtures of them. The best qualities of soaps, however, are scented cold by grinding or squeezing the previously dried soap between granite rollers after having been mixed with the perfumes. With perhaps the exception of Tonquin bean, the 'scents' used for snuffs and tobacco can scarcely be termed perfumes. There is a large consumption of fragrant essential oils in the manufacture of toilet powders; under the various names of rose powder, violet powder, &c.; a mixture of starch and orris, differently scented, is in general demand for drying the skin of infants after the bath. Precipitated chalk and powdered cuttle-fish bone, being perfumed with otto of roses, powdered myrrh, and camphor, become 'Dentifrice.' The ottos of peppermint, lavender, rose, and others are extensively used in flavouring sweetmeats and lozenges.

It is found that some flowers either do not yield an essential oil by distillation or yield it in quantities too small to be commercially available. The perfume from these is collected by the process called *enfleurage*. The flower-farmers of the Alpes Maritimes follow this method on a very large scale with the following flowers: rose, orange, acacia, violet, jasmine, tuberose, and jonquil. In the valley of the Var there are acres of flowers, the blossoms of which are gathered by women and children, and placed in little panniers like fishermen's baskets hung over the shoulders. They are then carried to the laboratory of flowers and weighed. In the laboratory great quantities of grease, lard, and beef-suet have been collected, melted, washed, and clarified. In each laboratory there are several thousand *châsses* or *châssis* ('sashes'), upon which the grease to be scented is spread, and upon this grease the blossoms are sprinkled or laid. The *châsse en verre* is, in fact, a frame with a glass in it as near as possible like a window-sash, only that the frame is two inches thicker, so that when one châsse is placed on another there is a space of four inches between every two glasses, thus allowing space for blossoms. The flower blossoms are changed every day, or every other day. The same grease, however, remains in the châsse so long as the particular plant being used yields blossoms. Each time the fresh flowers are put on, the grease is 'worked'—i.e. serrated with a knife—so as to offer a fresh surface of grease to absorb odour. The grease being *enfleurée* or 'enflowered' in this way for three weeks or more—in fact, so long as the plants produce blossoms, or the fat is capable of absorbing more odour—is at last scraped off the châsse, melted, strained, and poured into tin canisters, and is now fit for exportation. Fat or oil is perfumed with these same flowers by the process of *maceration*—i.e.

infusion of the flowers in oil or melted fat. For this end purified fat is melted in a *bain murie*, or warm water bath, and the fresh blossoms are infused in it for several hours. Fresh flowers being procured, the spent blossoms are strained away, and new flowers added repeatedly, so long as they can be procured. Oil does not require to be warmed, but improved results are obtained when it is slightly heated.

Jasmine and tuberose produce best perfumed grease by enfleurage, but rose, orange, and acacia give more satisfactory products by maceration; while violet and jonquil grease is best obtained by the joint processes—enfleurage followed by maceration. In the place of glass the space is filled with a wire-net on which is laid a *molleton*, or thick cotton fabric—moleskin, soaked with oil; on this the flowers are laid, just as with solid grease. In due time—that is, after repeated changing of the flowers—the oil becomes fragrant, and it is then pressed out of the moleskin cloth. Oil of jasmine, tuberose, &c. are prepared in this way. In order now to obtain the perfume of these flowers in the form used for scenting handkerchiefs, we have only to infuse the scented fat or oil, made by any of the above methods, in strong alcohol.

In extracting the odour from solid fat it has to be chopped up as fine as suet is chopped, put into the spirit, and left to infuse for about a month. In the case of scented oil it has to be repeatedly agitated with the spirit. The result is that the spirit extracts all the odour, becoming itself 'perfume,' while the grease again becomes odourless; thus is procured the essence of jasmine, essence of orange-flowers, essence of violets, and others already named, rose, tuberose, acacia, and jonquil. It is right to mention that the reason for producing a pomade—as these scented fats are technically termed—of orange-flowers is that the odour of the essential oil obtained by the distillation of orange-blossoms with water has not, in the least degree, the odour of the orange-blossoms from which it is obtained. The otto in fact undergoes a chemical change, and is no longer orange so far as odour is concerned. It is called Neroli, and is valued at from £16 to £20 the lb. weight, the variation depending upon the crop, which is of course greatly influenced by the season. The same remarks apply, though in a less marked degree, to rose.

Some idea of the magnitude of the flower industry may be gained from the following summary showing the weight of these particular flowers grown in the south of France in 1889: orange-blossoms, 1860 tons; roses, 930; violets, 147; jasmine, 147; tuberose, 74; cassia, 30; jonquil, 15. The seat of the rose industry for the production of otto of roses is Bulgaria, more especially the cantons of Kezanlik and Karlova. Here no less than 5660 lb. were produced in 1889 at an average value of say 20s. per oz.

Perfumes of Animal Origin.—Only four of these are used in perfumery—viz. Musk (q.v.), Ambergris (q.v.), Civet (q.v.), and Castor (q.v.). The aroma of musk freely imparts odour to every body with which it is in contact. Its power to impart odour is such that polished steel will become fragrant of it if the metal be shut in a box where there is musk, contact not being necessary. In perfumery manufacture tincture of musk is mixed with other odorous bodies to give permanence to the more evanescent perfumes or bouquets, the musk acting to them almost as a mordant does to a dyestuff. The usual statement as to the length of time that musk continues to give out odour is exaggerated. If fine musk be spread in thin layers upon any surface, and fully exposed to a changing current of air, all fragrance, it is said, will be gone in from six to twelve months. The finest musk, that which indeed is only really useful in perfumery, is distinguished as Tonquin musk, the average price of which is about 90s. per oz.

Civet is exceedingly potent as an odour, and when pure, and smelled at in the bulk of an ounce or so, is utterly insupportable from its nauseousness; in this respect it exceeds musk. When, however, civet is diluted so as to afford but minute quantities to the olfactories, then its sweet perfume is generally admitted; the fragrant principle is the same as that breathed by the beautiful narcissus. Civet is extensively used duly attenuated in perfumery. Its powerful and lasting odour enables it to be used in some soaps, and especially in sachets. It is one of the perfumes of 'Spanish Leather,' or Peau d'Espagne; the first gloves used in England were scented with it. Several thousand ounces are annually imported, the average price of which is about 9s. per oz.

Castor is in our day said to be almost obsolete as a perfume, but this is not so; for although it cannot be largely used in any given perfume on account of the almost blackness of its tincture, still when properly diluted it is extensively employed. Its perfume, when old especially, is exceedingly pleasant, and its *fixing* power is at least equal to that of musk. About 1500 lb. are annually imported, which fetch on the market about 36s. per lb.

Of late years the progress of scientific chemistry has led to the production of numerous odoriferous substances, some identical with the active odoriferous principles of plants. Among them may be mentioned vanillin, the principle of vanilla (methyl protocatechnic aldehyde); coumarin, of Tonquin bean (coumaric anhydride), and many derivatives of phenol; but the majority of this class of bodies are more used in confectionery for flavouring than in perfumery. The artificial musk of L. Bauer is a delightful perfume, and has many applications in perfumery; but it differs widely in odour from true musk.

The perfumes or bouquets of the shops are really mixtures of some or several of the primitive odours of the two above-mentioned groups. An example or two will illustrate this. 'Jockey Club Bouquet' is thus compounded: 2 gal. extract of orris; ½ gal. each of cassia, rose, and tuberose pomades; ½ gal. civet; ¼ gal. musk; 1½ gal. spirits of wine; 8 oz. bergamot otto; 1½ oz. rose. 'White Rose:' 2 pints extract rose pomade; 1 pint each cassia and jasmine; 1½ pint spirits of wine; ½ oz. rose otto; 1 drm. patchouli otto. It is obvious that the possible variety is infinite, since there are some sixty or more primitive odoriferous substances.

See the *Rose Industry of Bulgaria*, by Christo Christoff, Kezanlik (trans. by C. H. Piesse); and the 5th edition of Piesse's *Art of Perfumery* (Lond. 1891).

Pergamus, or PERGAMUM, anciently a city of Mysia in Asia Minor, on the river Caïcus, 15 miles from its mouth. According to tradition, the place was founded by Greeks from Arcadia. It first acquired prominence when Lysimachus, one of Alexander's generals, chose it as a stronghold in which to keep his treasures. Under Philetærus, his eunuch, whom he appointed guardian of his treasures, it became the capital of a state, 283 B.C. His successor, Eumenes I., maintained its independence against the Seleucids, although the title of king was first assumed by Attalus I., who reigned from 241 to 197 B.C., and defeated the Gauls in a great battle. He intimately allied himself with the Romans against Philip of Macedon, and this alliance subsisted throughout succeeding reigns, during which the kingdom continued to increase in extent and importance. Attalus III., surnamed Philometer, who died in 133 B.C., left it to the Romans, and under them it was one of the chief cities of Asia Minor. The native kings had

adorned it with grand sculptures, the work of artists belonging to the Pergamenian school, and collected a library only inferior to that of Alexandria. Pergamus was a special seat of the worship of Asclepius (Æsculapius); and it gave its name to Parchment (q.v.). It began to decline under the Byzantine emperors. The place still exists under the name *Bergama*, and is noted for the splendour and magnificence of its ruins, which embrace temples, palaces, aqueducts, gymnasia, amphitheatres, and city walls. These were excavated for the Prussian government by Humann, Bohn, and others, in 1878–86, many of the treasures being carried to Berlin.

Pergolese, Giovanni Battista, Italian musician, was born at Jesi, near Ancona, on 3d January 1710, studied music at Naples, and struck out an original style for himself. His first great work was the oratorio of *San Guglielmo*, composed in 1731, in which year appeared his bright and tuneful operetta of *La Serva Padrona*. This is his masterpiece; it was revived in London in 1873. In 1734 he was appointed *maestro di capella* of the Church of Loretto. In consequence of delicate health he removed to Pozzuoli, where he composed the cantata of *Orfeo* and his second masterpiece, the pathetic *Stabat Mater*, but died immediately afterwards on 16th March 1736. Besides the works quoted, Pergolese composed numerous operas, oratorios, and other sacred pieces.

Peri, according to the mythical lore of the East, a being begotten by fallen spirits, which spends its life in all imaginable delights, is immortal, but is for ever excluded from the joys of Paradise. It takes an intermediate place between angels and demons, and is either male or female. So far from there being only female Peris, as is supposed by some, and these the wives of the Devs, the Peris live, on the contrary, in constant warfare with these Devs. Otherwise, they are of the most innocuous character to mankind, and, just like the fairies with whom our own popular mythology has made us familiar, are when female of surpassing beauty. They belong to the great family of genii, or Jinn (see Demonology).

Periagua, a large canoe composed of the trunks of two trees, hollowed and united into one fabric; whereas an ordinary canoe is formed of the body of one tree only.

Perianth. See Flower.

Pericardium, a conical membranous sac containing the heart and the commencement of the great vessels, to the extent of about 2 inches from their origin. It is placed with its apex upwards behind the sternum in the interval between the pleuræ—the serous sacs in which the lungs are enclosed; while its base is attached to the diaphragm. It is a fibro-serous membrane, consisting of an external fibrous and an internal serous layer. The outer layer is a strong, dense, fibrous membrane; the serous layer invests the heart, and is then reflected on the inner surface of the fibrous layer. Like all serous membranes, it is a closed sac; its inner surface is smooth and glistening, and secretes a thin fluid which serves to facilitate the natural movements of the heart. It is inflammation of this serous sac which constitutes the disease known as pericarditis.

Diseases of the Pericardium.—Pericarditis is a disease of frequent occurrence; the result of a very large number of post-mortem examinations being to show that about one in twenty-three of all who die at an adult age exhibits traces of recent or old attacks of this disorder. The first change which takes place in an inflamed pericardium is a dulling of its glistening surface, with some congestion, which is speedily followed by effusion into the sac. The effusion is sometimes almost entirely fibrinous, in which case it coagulates, and gives rise to adhesions between the heart and the pericardium; or it may consist almost entirely of serum, which remains liquid; or it may be, and most frequently is, a mixture of the two. In a few cases it rapidly becomes purulent. In the cases that prove fatal when fibrinous fluid has been effused, but has not coagulated to such an extent as to cause complete adhesion of the heart to the pericardium, the partially coagulated fibrin or lymph is seen to be of a yellowish-white colour, and to occur in a rugged, shaggy, or cellular form. Laennec compared the surface on which the lymph is deposited to that which would be produced by suddenly separating two flat pieces of wood between which a thin layer of butter had been compressed. When the patient dies at a more advanced stage of the disease —viz. soon after the whole of the membrane has become adherent—incipient blood-vessels, in the form of red points and branching lines, are seen, indicating that organisation is commencing in the deposit, which if death had not ensued would have been finally converted into cellular or areolar tissue, and might have occasioned the complete obliteration of the pericardial cavity.

The recognition of the disease depends almost entirely upon the signs revealed by auscultation and percussion. The earliest is generally the *friction-sound*, or *to and fro murmur*, caused by rubbing together of the roughened surfaces, and heard to accompany the heart's action; but if fluid is effused it may speedily disappear. In this case percussion of the chest shows that the dull area occupied by the heart is larger than normal, while the impulse of the organ on the chest-wall cannot be felt. The symptoms, besides those common to all inflammations, are extremely variable: in some cases where pericarditis comes on in the course of other serious disease the patient makes no complaint, and the complication is only discovered during the routine examination of the chest. But there may be intense pain and tenderness on pressure in the region of the heart, great irregularity or feebleness of the heart's action, distressing breathlessness, delirium, &c.

Pericarditis is a disease which occasionally runs a very rapid course, and terminates fatally in forty-eight hours or less. In ordinary cases, however, which terminate in apparent recovery, the disease generally begins to yield in a week or ten days, and, excepting that adhesion may remain, the cure appears to be complete in three weeks or less. If the adhesions which have formed are dense and fibrous, they may impede the heart's action and lead to serious symptoms at some subsequent period.

Pericarditis rarely occurs as an independent disease. It may result from extension of an inflammation in a neighbouring organ, pleura, ribs, &c. It is no uncommon result of a contaminated state of the blood, such as occurs in the exanthematous diseases, especially scarlatina, and in Bright's disease of the kidney; but, beyond all comparison, it is of most frequent occurrence in association with acute Rheumatism (q.v.), of which it forms one of the most serious complications. It is often associated with inflammation of the muscular substance of the heart, and, especially in rheumatism, of the lining membrane as well.

The treatment of pericarditis at present in favour is much less active than when bleeding, mercurialisation, &c. were considered necessary. Complete rest in bed, light diet, with opium or other sedatives as required; general medication suited to the disease with which the pericarditis is associated; local application of poultices or cotton-wool, sometimes of leeches or blisters, are the chief measures

employed. In cases where there is extensive fluid effusion it may be necessary to aspirate, or, if the fluid be purulent, even to make a free incision.

The pericardium may also be distended with fluid without inflammation (hydropericardium) in the course of general dropsy; and occasionally is the seat of tumours, syphilitic or tubercular processes, &c.

Pericarp. See FRUIT.

Pericles. the greatest statesman of ancient Greece, was born of distinguished parentage in the early part of the 5th century B.C. His father was that Xanthippus who won the victory over the Persians at Mycale, 479 B.C.; and by his mother, Agariste, the niece of the great Athenian reformer Cleisthenes, he was connected with the princely line of Sicyon and the great house of the Alcmæonidæ. He received an elaborate education; but of all his teachers the one whom he most reverenced was the serene and humane philosopher Anaxagoras. Pericles was conspicuous all through his career for the singular dignity of his manners, the Olympian grandeur of his eloquence, his 'majestic intelligence,' in Plato's phrase, his sagacity, probity, and profound Athenian patriotism. Both in voice and in appearance he was so like Pisistratus that for some time he was afraid to come forward in political life. When he entered on public life Aristides had only recently died, Themistocles was an exile, and Cimon was fighting the battles of his country abroad. Although the family to which he belonged was good, it did not rank among the first in either wealth or influence, yet so transcendent were the abilities of Pericles that he rapidly rose to the highest power in the state as the leader of the dominant democracy. The sincerity of his attachment to the popular party has been questioned, but without a shadow of evidence. At anyrate the measures which either personally or through his adherents he brought forward and caused to be passed were always in favour of extending the privileges of the poorer class of the citizens, and, if he diminished the spirit of reverence for the ancient institutions of public life, he enlisted an immense body of citizens on the side of law. He extended enormously, if he did not originate, the practice of distributing gratuities among the citizens for military service, for acting as dicast and in the Ecclesia, and the like, as well as for admission to the theatre—then really a great school for manners and instruction. Pericles seems to have grasped very clearly, and to have held as firmly, the modern radical idea, that, as the state is supported by the taxation of the body of the citizens, it must govern with a view to general interests rather than to those of a caste alone.

About 463 Pericles, through the agency of his follower, Ephialtes, struck a great blow at the influence of the oligarchy, by causing the decree to be passed which deprived the Areopagus of its most important political powers. Shortly after the democracy obtained another triumph in the ostracism of Cimon (461). During the next few years the political course pursued by Pericles is less clearly intelligible to us, but it is safe to say that in general his attitude was hostile to the desire for foreign conquest or territorial aggrandisement, so prevalent among his ambitious fellow-citizens. Shortly after the battle of Tanagra (457), in which he showed conspicuous courage, Pericles magnanimously carried the measure for the recall of Cimon. His successful expeditions to the Thracian Chersonese, and to Sinope on the Black Sea, together with his colonies planted at Naxos, Andros, Oreus in Eubœa, Brea in Macedonia, and Ægina, as well as at Thurii in Italy and Amphipolis on the Strymon, did much to extend and confirm the naval supremacy of Athens, and afford a means of subsistence for her poorer citizens. But his greatest project was to form in concert with the other Hellenic states a grand Hellenic confederation in order to put an end to the mutually destructive wars of kindred peoples, and to make of Greece one mighty nation, fit to front the outlying world. The idea was not less sagacious than it was grand. Had it been accomplished the semi-barbarous Macedonians would have menaced the civilised Greeks in vain, and even Rome at a later period might perhaps have found the Adriatic, and not the Euphrates, the limit of her empire. But the Spartan aristocrats were utterly incapable of appreciating such exalted patriotism, or of understanding the political necessity for it, and by their secret intrigues the well-planned scheme was brought to nothing. Athens and Sparta were already in that mood towards each other which rendered the disaster of the Peloponnesian war inevitable. When the Spartans in 448 restored to the Delphians the guardianship of the temple and treasures of Delphi, of which they had been deprived by the Phocians, the Athenians immediately after marched an army thither, and reinstated the latter. Three years later an insurrection broke out in the tributary Megara and Eubœa, and the Spartans again appeared in the field as the allies of the insurgents. The position of Athens was critical. Pericles wisely declined to fight against all his enemies at once. A bribe of ten talents sent the Spartans home, and the insurgents were then thoroughly subdued. The thirty years' peace with Sparta (445) left him free to carry out his schemes for the internal prosperity of Athens.

Cimon was now dead and was succeeded in the leadership of the aristocratical party by Thucydides, son of Melesias, who in 444 B.C. made a strong effort to overthrow the supremacy of Pericles by attacking him in the popular assembly for squandering the public money on buildings and in festivals and amusements. Thucydides made an effective speech; but Pericles immediately rose and offered to execute the buildings at his own expense, if the citizens would allow him to put his own name upon them instead of theirs. The sarcasm was successful, Thucydides was ostracised, and to the end of his life Pericles reigned the undisputed master of the public policy of Athens. During the rest of his career 'there was,' says the historian Thucydides, 'in name a democracy, but in reality a government in the hands of the first man.' And the Athens of his day was the home of Æschylus, Sophocles, Euripides, Anaxagoras, Zeno, Protagoras, Socrates, as well as Myron and Phidias; while there flourished at the same time, but elsewhere in Greece, Herodotus, Hippocrates, Pindar, Empedocles, and Democritus. The centre of this splendid group was Pericles, of whom the truthful pen of Thucydides records that he never did anything unworthy of his high position, that he did not flatter the people or oppress his adversaries, and that with all his unlimited command of the public purse he was personally incorruptible.

Soon after this the Samian war broke out, in which Pericles gained high renown as a naval commander. This war originated in a quarrel between Miletus and the island of Samos, in which Athens was led to take part with the former. The Samians after an obstinate struggle were beaten, and a peace was concluded (439). The position in which Athens then stood towards many of the Greek states was peculiar. Since the time of the Persian invasion she had been the leader of the confederacy formed to resist the attacks of the powerful enemy, and the guardian of the confederate treasury kept in the isle of Delos. Pericles caused the treasury to

be removed to Athens, and, commuting the contingents of the allies for money, enormously increased the contributions to the patriotic fund, Athens herself undertaking to protect the confederacy. The grand charge against Pericles is that he applied the money thus obtained to other purposes than those for which it was designed; that, in short, he adorned and enriched Athens with the spoils of the allied states. To his mind Hellas was subordinate to Athens, and he confounded the splendour of the dominant city with the splendour of Greece in a manner possible to a man of poetic imagination, hardly to a man of the finest honour. His enemies, who dared not attack himself, struck at him in the persons of his friends. Phidias was flung into prison for the impiety of introducing portraits of himself and Pericles into the battle of the Amazons depicted on the shield of the goddess Athena in the Parthenon; the brilliant Aspasia, the famous mistress of Pericles, was arraigned on a charge of impiety, and only acquitted through the eloquence of Pericles on her behalf; while the aged Anaxagoras was driven from the city.

It is unnecessary to give a detailed account of all that Pericles did to make his native city the most glorious in the ancient world. Greek architecture and sculpture under his patronage reached perfection. To him Athens owed the Parthenon, the Erechtheum, left unfinished at his death, the Propylæa, the Odeum, and numberless other public and sacred edifices; he also liberally encouraged music and the drama; and during his rule industry and commerce were in so flourishing a condition that prosperity was universal in Attica.

At length in 431 the long-foreseen and inevitable Peloponnesian war broke out between Athens and Sparta. The plan of Pericles was for Athens to follow a defensive attitude, to defend the city itself, leaving Attica to be ravaged by the enemy, but to cripple the power of Sparta by harassing its coasts. The story of the war is told elsewhere; here it is enough to say that the result was fatal to Athens for reasons for which Pericles was only in small part to blame. He trusted in the ultimate success of Athens both from her superior wealth and from her possessing the command of the sea, but he had not calculated upon the deterioration in her citizens' spirit, nor upon the robust courage of the Bœotian and Spartan infantry. Nor was his advice to keep behind the city walls rather than face the enemy in the field best calculated to arouse the Athenians' courage. The plague ravaged the city in 430, and in the autumn of the following year Pericles himself died after a lingering fever. His two sons had been carried off by the plague; he had been harassed by a charge of peculation brought by Cleon, and the actual infliction of a fine by the dicastery, while he had been without office from July 430 to July 429; but before the last he recovered his hold over the Ecclesia, and was gratified in the closing days of his life by its legitimation of his son by Aspasia.

As a statesman his greatest fault was a failure to foresee that personal government is ultimately ruinous to a nation. He taught the people to follow a leader, but he could not perpetuate a descent of leaders like himself. Hence we cannot wonder, when days of trouble broke over Athens, how that men spoke bitterly of Pericles and all his glory. Yet he was a lofty-minded statesman, inspired by noble aspirations, and his heart was full of a noble love for the city and her citizens. Plutarch tells the story that as he lay dying and apparently unconscious his friends around his bed were passing in review the great achievements of his life, and the nine trophies which he had erected at different times for so many victories. The dying patriot quietly interrupted with the characteristic sentence—'What you praise in my life belongs partly to good fortune, and is, at best, common to me with many generals. But that of which I am proudest you have left unnoticed—no Athenian has ever put on mourning through any act of mine.'

For his life and character, see Thucydides and Plutarch; the histories of Greece of Thirlwall, Grote, and Curtius; W. Watkiss Lloyd's *Age of Pericles* (2 vols. 1875); and the excellent study by Evelyn Abbott in the 'Heroes of the Nations' series (1891).

Peridotite. See Igneous Rocks.

Périer, Casimir, French politician, was born at Grenoble, 21st October 1777. A Parisian banker, he condemned in 1817 the financial policy of the ministry, and thereby won a seat in the Chamber of Deputies. In 1828 he held the portfolio of finance under Martignac, but resigned it in August of the next year. Having taken an active part in the July revolution (1830), he was rewarded with a seat in the cabinet, but without a portfolio. When, however, Laffitte became President of the Council (November 2), Périer undertook the presidency of the Chamber of Deputies. On 13th March 1831 he succeeded Laffitte as minister; he sternly repressed all attempts at revolution, and governed by the *Juste Milieu* (q.v.) policy. He died of cholera, 16th May 1832. For his son, see Casimir-Périer.

Perigee. See Moon.

Périgueux, a town of France, formerly capital of Périgord, now in the department of Dordogne, and situated on the right bank of the Isle, a tributary of the Dordogne, 95 miles by rail NE. of Bordeaux. It consists of the ancient city, which is gloomy in aspect and has narrow streets, with numerous houses and other remains of mediæval and Renaissance architecture, and the Puy St Front, which until 1269 was a separate and a rival town. The cathedral of St Front is a Byzantine edifice, said to be a copy of St Mark's at Venice, built in 984–1047, but spoilt by 'restoration' in 1865. The town museum is especially rich in Roman and other antiquities. Statues of Montaigne, Fénelon, and the soldiers Daumesnil and Bugeaud adorn public places in the town. Iron is mined and worked, and woollens are manufactured. The celebrated *pâtés de Périgueux*, made of partridges and truffles, are largely exported. Pop. (1891) 30,725. Périgueux, a town of the highest antiquity, is the Gallic *Vesunna* mentioned by Cæsar. The Romans built another town on the opposite side of the river at the junction of five Roman roads. Close to the modern town are the remains of a vast amphitheatre, aqueducts, baths, and temples. The tower of Vesunna is the most remarkable fragment of Roman architecture. It is 89 feet high, 200 feet in circumference, and has walls 6 feet thick, but has neither doors nor windows. Its purpose is not known. The district of Périgord is noted for its Caves (q.v.) and archæological finds. See Flint Instruments.

Perihelion (Gr. *peri*, and *hēlios*, 'the sun'), that point in its orbit at which a planet is nearest the sun. See Planets, Orbit, Aphelion.

Perim, a barren island, and coaling and telegraph station, belonging to Britain, situated in the Strait of Bab-el-Mandeb, at the southern entrance to the Red Sea, 97 miles W. of Aden, 1½ from the Arabian shore, and 9 from the African. It is about 3½ miles long by 2½ wide, and crescent shaped, the two horns embracing a deep and spacious harbour. The island was held by the British in 1799–1800, and was again occupied in 1857. In 1883 it was made a coaling station, and soon began to be a rival to Aden. The island is under the jurisdiction of the governor of Bombay Presidency. Pop. about 400, mostly coolie coal-heavers. See H. Spalding, *Perim as it is* (1890).

Perinæum, the floor of the human pelvis. The anterior portion, situated in front of the anus, is called the *true perinæum*, or urethral portion of the perinæum; the posterior portion is called the anal portion or ischio-rectal region.

Period and Periodicity. One of the most striking features of the ordinary phenomena of nature is their tendency to recur and repeat themselves apparently indefinitely; and in general this repetition takes place at successive and practically equal intervals of time. The day, the month, the year are familiar examples of such periods, corresponding respectively to the earth's rotation, the moon's progression through its phases, and the earth's changes of distance from the sun. As a factor in human life the year is practically traced out by the climatic changes that accompany its progress, but strictly speaking it is the period determined by the recurring configurations of earth and sun. Many periodic phenomena of importance, such as eclipses, transits, occultations, depend like the moon's phases on the configurations of three bodies; and long before Newton's law of gravitation gave the key to the cosmic universe the periods of some of these had been discovered. See CHRONOLOGY (with its various cycles—the metonic of 19 years, the Calippic of 76 years, &c.), CYCLE, DAY, ECLIPSE, YEAR, &c.

When we look into the minute mechanism of nature we find here also the same prominence attached to periodic qualities. Sound and light consist physically of a vibratory or oscillatory motion of some sort; and to the accurate time periodicity of these motions we trace our sensations of harmony in music and colour. In certain respects, however, the periodicity is imperfect, each period not being an exact reproduction of its predecessor. Thus, a tuning-fork or pianoforte-string vibrating freely in air rapidly loses its vibratory character, and its motion steadily decays; and yet, judged by the pitch, the frequency or time periodicity remains the same throughout. In these and similar cases Viscosity (q.v.) ultimately transforms the original vibratory energy into heat (see ENERGY). Heat itself is believed to be some kind of vibratory energy of the molecules; and the spectroscope demonstrates that intense heat is certainly associated with definite periodic motions, giving rise to rays of corresponding periodicity (see SPECTRUM).

Passing now to the other extreme, we find, chiefly in astronomy, instances of long periods, some of which have not been completed within historic times, but of which the evidence is incontrovertible. The Precession (q.v.) of the equinoxes and the slow changes in the eccentricities and inclinations of planetary orbits may be mentioned by way of illustration. The geologist also has found evidence of periodic changes in the climatic conditions of the earth (see GLACIAL PERIOD, PLEISTOCENE). Generally periodicity involves the idea of time; but we may have periodic qualities depending on position or on grouping. A very good example of this is the periodic law of modern chemistry (see ATOMIC THEORY; also WAVE).

Life is as full of periodic phenomena as inanimate nature; but the increasing complexity of conditions makes the periodicity still less perfect. In the beating of the heart, in the alternation of waking and sleeping, of hunger and satiety we have examples of vital actions with a distinct periodic character.

Periodicals. Everything is a periodical that is published periodically. Every publication that is published more than once is necessarily published periodically. Therefore every publication, excepting a book complete in itself, may, strictly speaking, be described as a periodical, from the *Times* to *Whitaker's Almanac* and the *Post-office Directory*. The use of the term is, however, restricted in ordinary conversation to magazines and reviews appearing not less frequently than once a quarter, and not more frequently than twice a month. Weeklies, at least in Great Britain, have with a few exceptions ceased to be regarded as periodicals. As we have no fortnightlies, our periodicals may be said to be practically reduced to monthlies and quarterlies.

The refusal of the English-speaking world to tolerate fortnightly publications is as remarkable as it is unmistakable. In France and Italy and Belgium the fortnightly is regarded as the natural form of the high-class periodical. Outside these countries the fortnightly is practically unknown. Neither in Great Britain, nor in Greater Britain, has it been found possible to acclimatise the fortnightly. In Russia, in Germany, in Scandinavia, and in Spain and Portugal the periodicals are monthly. As if to remind the world of the constitutional incapacity of the English race to take its literature in bimonthly instalments, the *Fortnightly Review* is published monthly, but religiously announces on every cover that the issue of the 15th is suspended.

The number of periodicals is almost numberless. There are 332 monthlies in Italy alone, of which, at a moderate computation, 300 are read by no one outside Italy, and by probably fewer than 300 subscribers within the peninsula. But the number of periodicals of general interest that are worth calling periodicals are comparatively few. In Italy, for instance, there are hardly more than three which the outside world ever heard of. In France there are not more than four or five. Different countries excel in different departments. For pure literature and criticism the *Revue des Deux Mondes* has the first place. For illustration America leads easily, distancing all rivals with the *Century*, *Scribner's*, and *Harper's*; while in the second rank, although still ahead of foreign competitors, with one exception, come the *Cosmopolitan* and the *New England Magazine*. The only exception is the German magazine, *Velhagen und Klasing's Neue Monatshefte*. For general interest and solidity combined the English quarterlies and monthly miscellanies rank first, although they are hard pressed by the *Nouvelle Revue*, the *North American Review*, the *Forum*, and the *Arena*. For bulk the Russians surpass all the magazinists and reviewers of the world. The Russian monthly contains about three times as much printed matter as the *Nineteenth Century*. In proportion to its size Belgium leads the world in the multiplicity of its periodicals; but their prosperity is in an inverse proportion to their numbers. There is only one Portuguese monthly procurable in London.

The genesis of the periodical can be traced back for centuries, but the earlier publications of the kind bear about as much resemblance to the magazines and reviews of to-day that the eohippus bears to the winner of last year's Derby. The evolution of the modern magazine is usually traced back to the *Philosophical Transactions of the Royal Society*, which began to appear in 1665, but the true progenitor of our monthly miscellanies were the pamphlets which were spawned in such numbers in the heat of the revolutionary ferment of the 17th century. There was no regular periodicity in their appearance. Pamphleteers wrote as the spirit moved them, but their intermittent productions, in everything excepting the regularity of their appearance and the fact that each appeared singly instead of being stitched together with a dozen others, correspond very closely to the

monthly miscellanies which have now become the forum of civilisation. Milton, Marvell, and Defoe would all have been regular contributors to our monthly reviews if these publications had existed in their time. As they were without those conveniences of a more complex civilisation they were under the necessity of publishing each of their essays separately, often at their own risk, and very seldom to their own profit. In these as in other departments of human activity the middleman has been found indispensable alike for the profit of the producer and the convenience of consumers. The modern review is the monthly market where authors sell their wares, and of late the excessive multiplication of such marts has led to the publication of a kind of clearing-house of periodical literature in the *Review of Reviews* in London and New York, and *La Revue des Revues* in Paris.

The history of periodical literature in the 18th century as usually told in encyclopædias is little better than a parade of epitaphs from the tombstones of defunct reviews. Two notable facts, however, stand out clearly discernible on these sepulchral tablets. The first, the literary position given for the first time to periodical publications by Addison's editorship of the *Spectator*, although it was as little of a magazine as it was of a newssheet; and the second, the birth of the first monthly magazine of the modern type, when Cave the publisher brought out the *Gentleman's Magazine* in 1731. Of the *Weekly Memorials for the Ingenious*, published for twelve months in 1689, or the *Gentleman's Journal or Monthly Miscellany*, which appeared in 1692, nothing need be said. The *Gentleman's Magazine*, after making a fortune for its originator, has continued to flourish ever since.

If England may claim the honour of having invented the magazine, Scotland has the unquestioned right to be regarded as the originator of the review. A new era in periodical literature dawned when half-a-dozen brilliant young Scotsmen, with the assistance of Sydney Smith and a few less gifted Southrons, decided to establish the *Edinburgh Review* (q.v.) in the Whig interest in 1802. Their enterprise was rewarded by an immediate and signal success. The wit, the talent, the audacity, and the sheer impudence of the young reviewers startled the limited world of letters from centre to circumference, and convinced the Tories in no less than seven years that it was indispensable to counter the blue and yellow organ of militant Whiggery by a quarterly of unimpeachable orthodoxy. Thus it was that of the *Edinburgh* was born the *Quarterly* (q.v.), and the two great quarterlies have held the field ever since as the most authoritative exponents of the most respectable and scholarly element of the two great parties. The honour of initiative in these matters was not confined to the Scottish Whigs. Fifteen years after the *Edinburgh* first made its appearance a Scottish publisher on the other side, William Blackwood by name, achieved fame and fortune by an equally happy stroke in the publication of *Blackwood's Magazine*, a half-crown monthly which may be regarded as the parent of the political monthly miscellany. *Blackwood* was to the *Edinburgh* and the *Quarterly* what the saucy frigate was to the stately three-decker. It appeared twelve times a year, against their four numbers; it was infinitely more varied. It published serial fiction, poetry, prose, and that marvellous symposium, the *Noctes Ambrosianæ*, the secret of which perished with Christopher North. This again compelled the other side to retort by the publication of monthlies which are for the most part not only dead, but forgotten. The poet Campbell did his best in *Colburn's Monthly*, but for a dozen years the ascendency of the truculent but brilliant *Maga* was undisputed. Then in 1830 came *Fraser*—a magazine which, after many vicissitudes under many editors, is now extinct, while *Blackwood* still flourishes, less brutally truculent in its Toryism than of yore, but still bright, brilliant, and scholarly.

The Scottish initiative so remarkably asserted in the *Edinburgh* among the quarterlies and *Blackwood* among the monthlies was not exhausted. In 1832 *Chambers's Journal* made its appearance, marking the commencement of a new and more popular phase of magazinedom. It was published weekly, but was also issued in monthly parts. More than half a century has passed, and *Chambers* is still 'familiar in our mouths as household words, *Cassell's Family Paper* (now known as *Cassell's Family Magazine*) was not started till 1853. The old *Penny Magazine* (1832), published by the Society for the Diffusion of Useful Knowledge, deserves honourable mention. It was succeeded by the *Leisure Hour* in 1852, still one of the best illustrated sixpennies, published by the Religious Tract Society. Charles Dickens founded *Household Words* in 1850, and *All the Year Round* in 1859.

In 1859 Macmillan—again a Scot—published the first shilling magazine. This new departure was rapidly followed by the publication of the *Cornhill*, under the editorship of Thackeray, which at once achieved a phenomenal success; of *Temple Bar*, edited by George Augustus Sala; and of *London Society*, which has always relied chiefly upon fiction for its circulation.

In 1865 George Henry Lewes founded the *Fortnightly Review*, an avowed imitation of the *Revue des Deux Mondes*. It was started as a medium for the discussion of 'subjects which interest cultivated and thoughtful readers,' and it was to be published at intervals 'neither too distant for influence on passing questions, nor too brief for deliberation.' Mr Lewes was soon succeeded by Mr John Morley, who, in the sixteen years during which he was editor, gave a distinctive character to the new periodical literature of our time. The success of the *Fortnightly* led to the publication of the *Contemporary* (1866), with a bias as pronounced in favour of Christianity as the *Fortnightly* was biassed in favour of Agnosticism. This again was followed eleven years later by the publication of the *Nineteenth Century*, a miscellany entirely free from editorial bias of any kind. These three reviews have a practical monopoly of the field. They have as neighbours or poor relations —they can hardly be described as either rivals or competitors—the *National Review* (1883), which is Conservative; and the *Westminster*, which, originally founded in 1824 as a quarterly, was converted in 1887 into a monthly, while still remaining true to its original philosophical Radical principles. All these are published at half-a-crown. Most of them publish both signed and unsigned articles—the *Nineteenth Century* alone has consistently refused to insert any article not signed by the real name of the author. The circulation of the *Nineteenth Century* is the highest. It is the only half-crown review with more than 12,000 subscribers.

In 1850 the *Monthly Packet* was founded by Miss Yonge; it is written for young girls. Another Church of England shilling magazine was the *Newbery House Magazine*, issued from 1889 to 1894. Similar was the *Minster*, a sixpenny, founded in 1894. In 1860 *Good Words*, founded by Mr Strahan, under the editorship of Dr Norman Macleod, achieved so great a success as a sixpenny monthly, that it was followed in 1864 by the publication of the *Sunday Magazine*, edited by Dr Guthrie. The prosperity of the sixpennies led to the extinction of some of the older magazines. The *English Illustrated Magazine*, started in 1883, has repeatedly changed its management. In 1882 *Longman's* made its appearance at

sixpence. In the years 1887–89 *Murray's Magazine* appeared at a shilling. In 1890 the *Review of Reviews* appeared at sixpence, followed in 1891 by the *Strand Magazine;* both of these magazines achieved in the first year of their publication a circulation exceeding 100,000. The *Idler*, at first (1892) a sixpenny, now costs a shilling; the *Pall Mall Magazine* dates from 1893; the *Woman at Home* from 1894; the *Windsor* began in 1895. *Crampton's* (once *Chapman's*) *Magazine* is devoted to short stories; *M'Clure's Magazine* began in 1893; *Cassier's Magazine* (1891) concerns itself with industry. In 1898 Sir G. Newnes started *The Wide World Magazine* and *The Home Magazine*. The most widely circulated magazines, besides the *Strand*, *Chambers's Journal*, and *Pearson's*, are *Harmsworth's*, *Royal Magazine*, *The Puritan*, *Boy's Own Paper*, *Girl's Own Paper*, *Quiver*, *Cassell's Family Magazine*, *The Young Man*, *The Young Woman*, *Leisure Hour*, *Sunday at Home*, *Good Words*, and *Sunday Magazine*.

Among monthly periodicals devoted to art the oldest is the *Art Journal* (1839). The *Portfolio*, founded by Mr Hamerton in 1869, is since 1894 a series of monographs on artists. The *Magazine of Art* (1878), *The Artist*, and *The Studio* are well known. Music is represented by the *Musical Times* and a few others, and the drama by the *Theatre*.

The geographical societies publish their proceedings, and most of the sciences have their own reviews; the *National Review* has a line of its own. *The English Historical Review* and *The Scottish Review* (1883) fulfil special functions. *Cosmopolis* (1896) has sections in French and German. There are innumerable religious magazines. The Catholic Church is represented by the *Dublin Review* (quarterly), the *Month*, the *Lamp*, the *Lyceum*, and *St Peter's* (1898). The Wesleyan Methodists and the Primitives publish quarterlies; the Congregationalists have no longer the place in periodical literature they possessed when Dr Allen edited the *British Quarterly* and Paxton Hood the *Eclectic*. *The Jewish Quarterly* is read by many who are not Jews. The Salvation Army has a monthly in *All the World;* Mr Spurgeon established the *Sword and Trowel;* the *Animal World* is the organ of the Society for the Prevention of Cruelty to Animals, and the *Child's Guardian* of the Society for the Prevention of Cruelty to Children. The *United Service Magazine* is a monthly, *The Navy and Army* a weekly. The *Badminton* is devoted to sport. There are monthly magazines devoted to astrology, postage-stamps, chess, cricket, cycling, vegetarianism, anti-vaccination, Malthusianism, spiritualism, theosophy, and mysterious psychical phenomena; and most trades have a periodical devoted to their interests.—*Santa Lucia* is the monthly for the blind, in raised Braille type. See BLUE-BOOKS.

A general idea prevails among the public that to write for the magazines is a sure and easy road to competence. As a matter of fact, if we except writers of popular fiction, the number of contributors to periodical literature, not holding editorial appointments, who make £200 a year out of the magazines might probably be counted upon the fingers of one hand. The best paid contributions by the highest class reviews seldom exceed £1 a page of 500 words. The average review article does not yield its writer more than £15. As there are not ten men in England who contribute ten articles each a year to monthly miscellanies—the conclusion is obvious. Yet the flood of contributions rises ever higher. The late editor of the *Forum* recently calculated that he received from outsiders 3000 MSS. per annum, out of which he was usually able to use less than one per cent. 'Whaur's the harm,' asked the Ettrick Shepherd in *Noctes*, 'o' a few gude, sober, steady, judicious, regular, well-informed, versateele, and biddable contributors?' To this inquiry Christopher North replied, 'None such are to be found on earth—you must look for them in heaven.' From which it would seem that the editorial burden has changed little in fifty years. Poetry in particular is a drug in the market. In the same *Noctes* Christopher North said, 'I seldom pay for poetry. In cases of charity and courtesy—that is to say, of old women and young ones—my terms are a shilling for a sonnet, a dollar for a dramatic scene, and for a single book of an epic by way of a specimen, why, I do not grudge a sovereign.' This is probably more than the epic poet of our day would get for all his books from any magazine editor. Many periodicals, like hospitals, are supported entirely by voluntary contributions.

Of English-speaking lands the periodical flourishes chiefly in the United States. In the British colonies the English product seems to kill out the native production. Beyond a not very noteworthy quarterly in Sydney, and some diminutive religious magazines, Australia has no monthly magazines or reviews, except the quarterly *Imperial Review* of Melbourne. New Zealand has the *Monthly Review*. South Africa has produced no magazine of more than provincial fame. Canada had in the *Bystander* a unique magazine edited, written, and owned by Mr Goldwin Smith, but it no longer appears. Barbadoes has a little monthly in *Excelsior;* Honduras boasts the *Honduras Mining Journal*, formerly *Honduras Progress;* and British Guiana publishes *Timehri*, a quarterly. Among the periodicals in English published on the Continent are the *Esquiline* (Rome) and *Anglo-Austria* (Meran). India has the *Calcutta Review* (quarterly), and the monthlies, the *National Magazine*, the *Indian Magazine and Review*, and the *Allahabad Review;* but the publications of London and Edinburgh overshadow the periodicals of the rest of the empire. The *Asiatic Quarterly* now embraces colonial and African topics; otherwise the colonies are not specially represented except by the small monthly papers *Imperial Federation* and *Greater Britain*.

The American magazines are every year becoming more and more formidable competitors of the English periodicals even in Great Britain. They have an enormous advantage in the excellent American postal rule by which all periodically issued printed matter is conveyed by the mails at special rates not exceeding a halfpenny per pound. In England it costs threepence to send a pound of printed matter, if published monthly, through the post from St-Martin's-le-Grand to Downing Street—although the post-office will carry a pound weight of printed matter if it is issued weekly for one halfpenny from Land's End to John o' Groats. This absurd method of handicapping monthly publications is unknown in the United States. The American magazines are distinguished for the excellence of their typography and the clearness and artistic character of their illustrations. There is no such illustrated magazine as the *Century* published outside of New York. The American illustrated magazine is making its way rapidly throughout the whole British Empire. The *Century* and *Harper* circulate largely in India. *Munsey's*, at ten cents, has a circulation of 700,000. The *Cosmopolitan* has now begun to publish in London as well as in New York. The *New England Magazine* is also a well-illustrated monthly. Of the non-illustrated American magazines the *Atlantic Monthly* (1858) is one of the oldest and most respectable. *Lippincott* publishes monthly a complete novel of high character, with a selection of miscellaneous essays. All these are now

published simultaneously in London and New York. But the three monthly reviews which correspond to the *Nineteenth Century*, *Fortnightly*, and *Contemporary* are the *North American* (1815), the *Forum* (1886), and the *Arena* (1888). The *Arena* accompanies its letterpress with portraits and occasional illustrations. It has a distinctive rôle of its own, being the arena for the free discussion of all the heresies which seem to foreshadow the trend of progress. The *Forum* is steady, sensible, and instructive. The *North American* is more lively and up to date. All these publish signed articles. The *Arena* publishes stories. English writers contribute largely to the *North American* and the *Forum*. In theology there are the *Andover Review*, *Homiletic Review*, *Church Review*, *American Catholic Quarterly*, *Catholic World*, &c.

Up to 1891 some of the English reviews were in the habit of forwarding printed sheets to New York every month; but hitherto the chief knowledge of the American reader concerning English periodicals has been gained from the pages of *Littell's Living Age* and *Current Literature*, two publications which are freely fed from the pages of English magazines and reviews. The Americans produce copiously the more solid and ponderous quarterlies. They are great on economics and education, and theology of the slightly antiquated pattern. Their *Popular Science Monthly* is one of the best of its kind, and the *Chautauquan* is quite unique—a magazine that aspires to be a substitute for a university.

Coming to foreign periodicals the first place naturally belongs to France, whose two principal reviews, the *Revue des Deux Mondes* (1829) and the *Nouvelle Revue* (1879), are read throughout the whole Latin world. It is a curious fact that the *Revue des Deux Mondes* has more subscribers outside France than within the republic. There is a great Latin belt of a French reading public stretching from Madrid to Bucharest, and among them the *Revue* reigns as it has long reigned supreme. The *Nouvelle Revue* owes its character and its charm to its editor, Madame Adam. Both of these great reviews devote much more space to the chronicle of the events of the month than any English or American periodical. The *Cosmopolitain*, the oldest French review, founded in 1829, is published on the 10th and 25th of each month. It is Catholic with the traditions of Montalembert. Excluding the high-class art magazines, like the *Gazette des Beaux-Arts*, there is no illustrated periodical in France, although of late *La Revue des Revues* has been making praiseworthy efforts to fill the gap.

Germany has many literary capitals, and her magazines do not all emanate from a single centre. Most of the popular German magazines, such as *Die Gartenlaube* and *Ueber Land und Meer*, are issued both weekly and monthly. They are copiously illustrated, and form a great contrast in their readableness to such ponderous reviews as the *Deutsche Rundschau*, the *Deutsche Revue*, *Unsere Zeit*, and the *Preussische Jahrbücher*. Among the illustrated popular magazines, *Vom Fels zum Meer* deservedly holds a high place. The best of the German magazines is *Velhagen und Klasing's Neue Monatshefte*, already mentioned. *Westermann's Deutsche Illustrirte Monatshefte* and *Nord und Süd* are also high-class magazines. German periodical literature is very rich in theological reviews; and several periodicals represent the various new schools of literature—e.g. the *Gesellschaft* is the organ of the Realists. Similarly the *Moderne Rundschau*, the *Deutsche Dichtung*, and others are conducted by members of the new schools and tendencies.

In Russia the unwieldy review forms the chief field for the manifestation of the literary talent of the nation. These reviews are published either at Moscow or at St Petersburg. They are hardly seen outside Russia; they are not illustrated, and their circulation is comparatively small. In Italy the *Nuova Antologia*, *La Rassegna Nazionale*, and *La Civilta Cattolica* are the only periodicals excepting those purely scientific or professional that are seen outside the peninsula. Spain has *España Moderna* or *Revista Ibero-Americana* and *Revista Contemporánea;* Holland, *De Gids*, *Vragen des Tijds*, and *Elsevier's Geillustreird Maandschrift;* Scandinavia, *Tilskueren*, *Svensk Tidskrift*, *Nordisk Tidskrift*, *Samtiden*.

In concluding this rapid survey of the periodical literature of the world, mention should be made of the latest born and most polyglot of monthlies, the *Pantobiblion*, a magazine published in St Petersburg in no fewer than fifteen different languages. It aims at providing professional and scientific men of all countries with a clue to the periodical literature, technical and scientific, of all the world. It is like a periodical monument reared to the memory of the Tower of Babel.

Poole's *Index to Periodical Literature*, a dictionary of the more important articles in the quarterlies, monthlies, and many weeklies, is edited by a Chicago librarian. Stead's popular *Index to the Periodicals of 1890* has been issued in London, and the publication is to be continued annually. See also the articles Newspaper and Book-trade in this work.

Periophthalmus, a remarkable genus of acanthopterous fishes, allied to the gobies. Their eyes protrude and are very mobile; their pectoral fins can be used as legs. Several species occur on the coasts of the Indian Ocean and Western Africa; of these the best known is *P. koelreuteri*.

Periophthalmus koelreuteri.
(From Hickson's *Naturalist in North Celebes*, 1890.)

This fish lives about low tide-mark on the muddy flats or among rocks, and by means of its pectoral fins and tail hops along in search of crustaceans, insects, and gastropods. Respiration seems to be effected through the skin of the tail even more than by the gills. They cling by their fins to rocks and mangrove-roots, and keep their tails in the water; or they climb entirely out of the water, and jump with agility when disturbed.

Periosti'tis, inflammation of the periosteum, the tough fibrous membrane which surrounds the various bones (see Bone). It generally occurs on the surface of thinly-covered bones, such as the tibia, clavicles, and cranial bones. Its chief causes are (1) a *syphilitic taint;* (2) *rheumatism;* and (3) *scrofula;* but its occurrence is often determined by injury to the part. The affection, especially when due to the first or second of the above causes, is usually accompanied with considerable nocturnal pain. If the disease occurs in an acute form it must be treated with leeches, fomentations, and the other ordinary antiphlogistic remedies. If severe, an incision through the inflamed tissue is sometimes the most effectual treatment.

Peripatetic Philosophy, a designation of the philosophy of Aristotle (q.v.) and of his followers. It is of doubtful origin, being supposed to have been derived either from his custom of occasionally walking about (*peripatein*) during the delivery of his lectures, or from the place in which they were delivered being a shaded walk.

Peripatus, a genus occupying a unique position between myriopods and insects on the one hand and annelids on the other. For, along with the tracheæ or air-tubes characteristic of insects, Peripatus has the nephridia or excretory tubes characteristic of the higher worms. The body measures about two inches in length, is shaped like that of a worm or caterpillar, but without external rings, bears numerous (14 to 42) imperfectly-jointed stump-like clawed feet, and has a soft skin, with little of that chitin which is abundant as a cuticular product in other arthropods. The head bears a pair of mobile antennæ, a pair of mandibles in the mouth, and a pair of oral papillæ from which slime oozes. With this Peripatus catches its prey of small insects, &c. The species live in moist places under stones and bark, and are nocturnal in their habits. Professor Sedgwick says that 'the exquisite sensitiveness and constantly changing form of the antennæ, the well-rounded plump body, the eyes set like small diamonds on the side of the head, the delicate feet, and, above all, the rich colouring and velvety texture of the skin all combine to give these animals an aspect of quite exceptional beauty.' There are many remarkable structural features: thus, the ventral nerves are widely separate; the eyes are simple, like those of an annelid; the body-cavity is divided into three longitudinal compartments, from which the cavities of the legs are furthermore distinct. The sexes are separate. The development varies considerably in different species, for the ova may contain a considerable amount of yolk or none at all. In several it has been observed that the cells of the embryo are for a prolonged period indistinctly separate from one another. The embryos develop within the body of the mother-animals; when born they resemble the parents except in size. The distribution is very wide; in South Africa there are four species—e.g. *P. capensis*, *P. balfouri;* in New Zealand, *P. novæ Zealandiæ;* in Queensland, *P. leuckartii;* in Caracas, *P. edwardsii;* and others from Demerara, Trinidad, St Vincent, Chili, Quito, &c. The distribution, the structure, and the development of Peripatus all suggest that it is the survivor of an archaic type. The genus is usually dignified as a special class of Arthropods—Prototracheata. See figure under CATERPILLAR; and monograph by A. Sedgwick, *Quart. Journ. Micr. Sci.*, xxviii. (1888).

Perissodactyla. See ARTIODACTYLA.

Peristaltic Motion, the action of the muscular coat of the intestines, by which the substances contained within it are regularly moved onward. See DIGESTION.

Peritoneum (Gr. *periteinein*, 'to extend around'), a serous membrane, and, like all membranes of this class, a shut sac, which, however, in the female is not completely closed, as the Fallopian tubes communicate with it by their free extremities. The peritoneum more or less completely invests all the viscera lying in the abdominal and pelvic cavities, and is then reflected upon the walls of the abdomen, so that there is a visceral and a parietal layer. Numerous folds are formed by the visceral layer as it passes from one organ to another. They serve to hold the parts in position, and at the same time enclose vessels and nerves. Some of these folds are termed *Ligaments*, from their serving to support the organs. Thus, we have ligaments of the liver, spleen, bladder, and uterus formed by peritoneal folds. Others are termed *Mesenteries* (from the Gr. *meson*, 'the middle,' and *enteron*, 'the intestine'), and connect the intestines with the vertebral column. They are the Mesentery proper, the ascending transverse, and descending meso-colon, and the meso-rectum. Lastly, there are folds called *Omenta*, which proceed from one viscus to another. The great omentum always contains some adipose tissue, which in persons inclined to corpulency often accumulates to an enormous extent. Its use appears to be (1) to protect the intestines from cold by covering them anteriorly as with an apron, and (2) to facilitate their movement upon each other during their vermicular action.

DISEASES OF THE PERITONEUM.—The peritoneum often becomes the seat of dropsical effusion, both in cases of general dropsy and in cirrhosis of the liver. It may also be attacked by cancer, either primary or secondary, and, like all the serous membranes, readily takes on inflammation from various exciting causes. This inflammation is termed Peritonitis, and may be either an acute or a chronic disease.

Acute Peritonitis, inflammation of the coating of the bowels, but often popularly spoken of as 'inflammation of the bowels,' generally presents well-marked symptoms. It sometimes commences with a chill, but severe pain in the abdomen is usually the first symptom. The pain is at first sometimes confined to particular spots (usually in the lower part of the abdomen), but it soon extends over the whole abdominal region. It is increased, on pressure, to such an extent that the patient cannot even bear the weight of the bedclothes; and to avoid, as far as possible, internal pressure upon the peritoneum, he lies perfectly still, on his back, with the legs drawn up, and breathes by means of the ribs, in consequence of the pain occasioned by the descent of the diaphragm in inspiration. The breathing is naturally shallow in these cases, and, less air being admitted at each movement of respiration, the number of those movements is increased. There are perhaps forty or even sixty respirations executed in a minute, instead of eighteen or twenty. The pulse is usually very frequent, often 120 or more in the minute, and small and tense, though occasionally strong and full at the commencement of the attack; the temperature is usually raised, and vomiting is almost always an early symptom. After the disease has continued for a certain time the belly becomes tense and swollen; the enlargement being caused at first by flatus, and afterwards also by the effusion of fluid, as may be ascertained by percussion and palpation. The progress of the disease is in general rapid. In fatal cases death usually takes place within a week, and often sooner. The symptoms indicating that the disease is advancing towards a fatal termination are great distention of the abdomen, a very frequent and feeble pulse, a pinched and extremely anxious appearance of the face, and cold sweats.

Peritonitis rarely arises from exposure to cold alone. It is frequently the result of local violence, and of wounds penetrating the peritoneal sac, including various surgical operations. In the majority of cases it is due to extension of some inflammatory process in one of the abdominal viscera, particularly the hollow viscera (stomach, intestines, gall-bladder, urinary-bladder, womb). It is sometimes caused by Bright's disease. Two varieties call for special mention: *puerperal peritonitis*, due to extension of septic inflammation of the lining membrane of the womb after child-birth or miscarriage, a most fatal form of disease; and *peritonitis* from *perforation* of one of the hollow

viscera, which is characterised by the suddenness of the attack, intense pain, incapable of mitigation by medicine, all at once arising in some part of the abdomen, the whole of which soon becomes tender in every part. This form of the disease is generally fatal, death usually ensuing within two days, and sometimes within a few hours. Perforation of the small intestine, in consequence of ulceration of its glands, is of not uncommon occurrence in typhoid fever, and sometimes occurs in phthisis. That apparently useless structure, the vermiform appendage of the cæcum, is a comparatively frequent seat of perforation. Sometimes it is the stomach which is perforated, and in these cases the patients are usually unmarried women (especially domestic servants), who may have previously appeared in good health, or at most have complained of slight dyspepsia.

At the onset of the disease it is not always easy to distinguish it from Colic (q.v.), but the progress of the case will soon settle the question. With this exception, the only disease with which peritonitis is likely to be confounded by the well-educated practitioner is a peculiar form of hysteria; but the age and sex of the patient, the presence of hysteria in other forms, and the general history of the patient and of her symptoms will almost always lead to a correct diagnosis of the disease.

The treatment of a case of peritonitis must depend upon the cause to which it is due. Perfect rest in bed is essential. In the great majority of cases opium should be given in full doses, to allay pain and keep the bowels at rest. But in some, particularly those following surgical operations on the female generative organs, the opposite plan, treatment by saline purgatives, introduced by Lawson Tait, gives excellent results. The diet must be light and fluid; in cases of perforation of the stomach no food or even drink must be given by the mouth. Light poultices, or hot fomentations, should be constantly applied to the abdomen; leeches are sometimes useful. In cases of perforation from disease or injury, and of suppurative peritonitis, life has frequently been saved during recent years by prompt surgical interference.

Chronic Peritonitis occurs in two forms, which differ in their origin and degree of fatality, but are very similar in their symptoms. In the first the inflammation is of the ordinary character, and, although the disease sometimes originates spontaneously, it is more frequently the sequel of an imperfectly cured acute attack; in the second it depends upon tubercular inflammation, and is generally met with in persons of a scrofulous constitution. The symptoms of chronic peritonitis are more obscure than those of the acute form. There is abdominal pain, often slight, and not always constant, which is increased by pressure, or sometimes is felt only when pressure is made. The patient complains of a sensation of fullness and tension of the belly, although its size is not visibly increased; of a loss of appetite; and of nausea and vomiting; and the bowels are usually more or less out of order. After a time the abdomen enlarges, and becomes tympanitic, or more or less filled with fluid; and death gradually ensues from debility and emaciation, unless the fatal issue is accelerated by an acute inflammatory attack. It is not always easy to determine, during life, whether the disease belongs to the first or second form. When its origin cannot be traced to a preceding acute attack, to local abdominal injury, or to chronic affections of the abdominal viscera, there is strong reason to believe it to be of the tubercular form, especially if the general constitution and the hereditary tendencies of the patient point in the same direction.

Little can be done in the way of medical treatment, especially in the tubercular form, further than mitigating the most distressing symptoms, and possibly retarding the final issue, though recovery sometimes follows the continuous application of mercurial liniment. In chronic, even tubercular peritonitis, however, as in the acute disease, surgical interference, either by aspiration or by free opening of the abdominal cavity, has given very encouraging results in many cases.

Periwinkle (*Vinca*), a genus of plants of the natural order Apocynaceæ, having a 5-cleft calyx, and a salver-shaped corolla bearded at the throat, with five obliquely truncated segments. The leaves are opposite and evergreen; the flowers grow singly or in pairs from the axils of the leaves. The Lesser Periwinkle (*V. minor*), a native of many parts of Europe and of the southern parts of Britain, growing in woods and thickets, is a half-shrubby plant with trailing stems, rooting at their extremities, ovato-lanceolate leaves, and pale-blue —sometimes white or reddish-purple—salver-shaped flowers. The Greater Periwinkle (*V. major*), which has much larger flowers and ovato-cordate leaves, is a native of the south of Europe, and is found in a few places in the south of England. Both of these species are very commonly planted in shrubberies and gardens, rapidly cover unsightly objects with pleasing green foliage, and produce their beautiful flowers at almost all seasons of the year, even in winter when the weather is mild. The Herbaceous Periwinkle (*V. herbacea*), a Hungarian species, is remarkable for the abundance of its flowers. The Yellow Periwinkle (*V. lutea*) is a native of the southern parts of North America. The Rose-coloured Periwinkle (*V. rosea*), a native of Madagascar, is a favourite hothouse plant.

Periwinkle (*Littorina*), a genus of marine Gasteropods, represented by several species on British coasts. The commonest, *Littorina littorea*, is abundant between tide-marks on the rocks, and is often collected and used for food. It is boiled in its shell, extracted as eaten, and is very palatable. Periwinkles crawl about under water, but usually remain passive when left uncovered by the tide. Without water they can survive for many hours, and they are also able to endure a considerable freshening of the salt water. They feed on seaweeds, and are often useful in keeping beds of young oysters from being smothered. Periwinkles drawn up from 70 to 80 fathoms were first in 1889 used as bait for cod-fishing on the banks of Newfoundland. The edible species is oviparous, but in *L. rudis*, which is usually common nearer high-water mark, the young are hatched and have a hard shell before they leave the mother. These shells are apt to make this periwinkle gritty, and therefore it is not used as food. Among the structural characters of the periwinkle the substantial shell of few whorls, the closely-fitting, horny operculum, the nearly circular shell aperture without any siphon-notch are at once evident. Species of Littorina occur on almost all coasts, and there are about half a hundred in all. It should be carefully noticed that the periwinkle is often called the Wilk, Wulk, or Whelk in Scotland, but it is not nearly related to the true whelks (Purpura, Buccinum, &c.). See WHELK.

Perizzites, the Canaanites of Galilee. See PALESTINE, Vol. VII. p. 712.

Perjury is the crime committed by one who, when giving evidence on oath as a witness in a court of justice, or before some constituted authority of the same kind, gives evidence which he knows to be false. But in order to make the giving of false evidence a crime the evidence must be material—i.e. it must affect the decision of some question before the court. If the falsehood occurred as to some trifling or immaterial fact no crime is

committed. Moreover, it is necessary, in proving the crime, that at least two persons should be able to testify to the falsehood of the matter, so that there might be a majority of oaths on the matter—there being then two oaths to one. But this rule is satisfied though both witnesses do not testify to one point. The perjury must also have taken place before some court or tribunal which had power to administer the oath (see OATH). Though in some courts affirmations are allowed instead of oaths, yet the punishment for false affirmation is made precisely the same as for false swearing. The punishment for perjury was, before the Conquest, sometimes death or cutting out the tongue; perjury is now a misdemeanour, punishable by imprisonment with hard labour. The crime of Subornation of Perjury—i.e. the persuading or procuring a person to give false evidence—is also punishable as a distinct offence; if the false evidence is not given the crime is incitement. In many states of the American Union the crime of false swearing, recognised by common law, is further particularly defined by statute. The violation of an oath of office is not perjury; nor is a false affidavit to an account rendered to an administrator technically perjury, nor false evidence in depositions taken by consent by unauthorised persons.

Perkeniers, See MOLUCCAS.

Perleberg, a town of the Prussian province of Brandenburg, 80 miles NW. of Berlin. Pop. 7825.

Perlitic Structure, in Petrography, is a structure seen in some vitreous rocks. These rocks seem as if made up of little pearly or enamel-like spheroids, each of which is subdivided into a number of concentric coats by curved cracks, roughly parallel to its boundary. The spheroids usually lie packed between rectilinear or curved fissures that traverse the rock in all directions. Perlite is the name given to rocks showing this structure.

Perm, a town of Russia, on the Kama, by which it is 685 miles NE. of Kazan. It is the chief seat of the extensive transit trade between European Russia and Siberia, and has a cathedral, tanneries, distilleries, flour-mills, and oil-works, and a government arsenal and cannon-foundry. Pop. 45,403. The *government* has an area of 128,211 sq. m. and a pop. (1897) of 3,003,208, and is exceptionally rich in minerals.

Permian System. In Britain this series of strata rests unconformably upon the Carboniferous rocks. It consists of the following groups:

UPPER RED SANDSTONES, clays and gypsum (50 to 100 feet thick in east of England; west of Pennine chain, 600 feet thick).
MAGNESIAN LIMESTONE (500 to 600 feet) = Zechstein of Germany.
MARL SLATE (about 60 feet) = Kupferschiefer.
LOWER RED AND MOTTLED SANDSTONES, with conglomerates and breccias (3000 feet in Cumberland; in the east of England not over 250 feet) = Rothliegende of Germany.

The Lower Red Sandstones are greatly developed in Staffordshire, Cheshire, and Lancashire, and the Vale of Eden in Westmorland and Cumberland. Small areas also occur in the valleys of the Nith and Annan and in Ayrshire; and similar areas appear in the districts of Down, Tyrone, and Armagh in Ireland. The breccias met with in this group often contain erratics, and have the general aspect of glacial accumulations; and Sir A. Ramsay thought they probably indicate the occurrence of a glacial episode in the Permian period. In the Scottish area the rocks contain sheets of lava-form rocks and tuffs, associated with which are many small filled-up volcanic vents or *necks*. The most important member of the overlying groups is the Magnesian limestone, which is the chief repository of Permian fossils. Many of its beds assume curious concretionary forms, as is well seen on the coast of Durham.

In Germany the Permian consists of an upper and lower group—hence the system is often termed Dyas—the Zechstein and Kupferschiefer forming the upper, and the Rothliegende the lower group. Volcanic rocks are associated with the latter. The Kupferschiefer has long been famous for its ores of copper and other metals, and fossil fishes; while associated with the Zechstein are beds of anhydrite, gypsum, rock-salt, and bituminous shales. In Russia the system occupies an area of more than 15,000 sq. m. between Moscow and the Urals. It is well developed in the government of Perm, from which it derives it name. While the German Dyas presents the same general features as the Permian of Durham and the east of England, the Russian development resembles the Permians of the Midlands and north-west of England—limestone being quite a subordinate formation, and often wanting. Although there is commonly an unconformity between the Permian and the Carboniferous, yet in some places, as at Autun in the heart of France, a conformable passage is traced from the coal-measures into the Permian. The same is the case in North America, where in the western part of that continent no hard and fast line can be drawn between the two systems—the Carboniferous graduating upwards into the Permian.

Life of the Period.—The Permian strata as a whole are not rich in fossils—the red sandstones which form so large a portion of the system being for the most part barren. As contrasted with the flora of the Carboniferous period that of the Permian is poor and meagre. But that poverty may be only apparent—the conditions for its preservation not having been so favourable as during Carboniferous times. It may be considered as an impoverished continuation of the Carboniferous flora. The most common plants are ferns—both herbaceous and arborescent—many of the genera being Carboniferous, while others, such as Callipteris, are not known as Carboniferous forms. Conifers were likewise numerous, especially the yew-like Walchia and the cone-bearing Ullmannia. Traces of what some suppose to have been cycads (Nœggerathia) are met with in Permian strata. Finally, it may be noted that many characteristic Palæozoic types died out in Permian times, such as the Lepidodendroids, Sigillarioids, and Calamites. The animal life of the period is somewhat better represented; but it too appears impoverished when contrasted with that which flourished in the preceding Carboniferous period. We note that rugose corals, so abundant in the older Palæozoic rocks, are very sparingly met with in Permian strata; even tabulate forms are feebly represented. Polyzoa are fairly numerous in the Magnesian limestone. Amongst brachiopods the more abundant types are survivals from the Carboniferous, as Producta, Spirifera, Strophalosia. Lamellibranchs are somewhat more numerous than brachiopods, common forms being Schizodus, Bakevellia, Gervillia, &c. Gasteropods (Murchisonia, Pleurotomaria) are feebly represented, and the same is the case with the cephalopods (Nautilus, Orthoceras, Cyrtoceras). It is worthy of note that the trilobites are represented by one form (Phillipsia)—the last appearance of that eminently Palæozoic order. Among the fishes the principal genera are Palæoniscus and Platysomus. Amphibians seem to have abounded; they are all labyrinthodonts (Archegosaurus, Branchiosaurus, Pelosaurus). At this horizon true reptiles (Proterosaurus) make their earliest appearance.

In most parts of Europe where Permian strata are developed they rest unconformably on Carboniferous and other rocks, from which it is evident

that towards the close of Carboniferous times considerable earth-movements took place. These caused the sea to disappear from wide regions in Europe, and resulted eventually in the isolation of certain areas, which thus became inland seas or salt lakes. In these latter mottled sandstones, dolomitic limestones, rock-salt, and gypsum were accumulated, so that the conditions were not favourable to life. One or more such inland seas covered large areas of what is now central England, and extended into southern Scotland and the north of Ireland. Similar large inland seas existed in middle and eastern Europe. The strata accumulated in such basins show plentiful footprints and other indications of shallow-water conditions, such as worm-tracks, sun-cracks, rain-pittings, and ripple-marks—evidence which indicates that the level of the lakes was often abnormally lowered during dry seasons, leaving wide tracts exposed over which crawled annelids, amphibians, and reptiles. Volcanic action was rife in Scotland and Germany, and it has been suggested that the abundant and well-preserved fish remains which occur in the Kupferschiefer may have been poisoned by the sudden influx of mineral springs connected with the volcanic disturbances of the time. Some of the inland seas may have had occasional connection with the open sea for longer or shorter periods, as, for example, during the formation of the thicker fossiliferous limestones. But, taken as a whole, the general character of the strata is that of accumulations formed in inland seas. The climate of the period, so far as one can judge from the aspect of flora and fauna, was probably mild and genial. Nevertheless the occurrence of coarse breccias, with their scratched stones and erratics, in the Permian of Britain and the Continent, and the similar appearances met with in strata, which are believed to be of the same age, in India, Australia, and South Africa seem hard to explain without the agency of floating ice.

Permissive Bill. See LOCAL OPTION.

Permutations and Combinations. A combination, in Mathematics, is a selection of a number of objects from a given set of objects, without any regard to the order in which they are placed. The objects are called elements, and the combinations are divided into classes, according to the number of elements in each. Let the given elements be the four letters *a, b, c, d;* the binary combinations, or selections of two, are *ab, ac, ad, bc, bd, cd*—six in all; the combinations of three are *abc, abd, acd, bcd*—four in all; while there is only one combination of four—viz. *abcd.*

Permutation, again, has reference to the order of arrangement; thus, the two elements, *a* and *b*, may stand *ab* or *ba*, so that every combination of two gives two permutations; the three elements, *a, b,* and *c*, may stand *abc, acb, bac, bca, cab, cba*, one combination of three thus affording six permutations. The combinations of any order with all their permutations are called the *Variations.* Formulas are given in works of algebra for calculating the number of permutations or combinations in any given case. Suppose seven lottery-tickets marked 1, 2, 3, to 7, and that two are to be drawn; if it is asked how many possible pairs of numbers there are, this is a question of the number of combinations of seven elements, *two* together, which is found to be 21. If we want to know how many times the same seven persons could sit down to table together with a different arrangement each time, this is to ask how many permutations seven objects admit of, and the formula gives $7 \times 6 \times 5 \times 4 \times 3 \times 2 = 5040$. The theory of probabilities is founded on the laws of combination. Thus, in the case of drawing two tickets out of seven, since there are 21 possible pairs, the chance or probability of drawing any particular pair is 1 in 21, or $\frac{1}{21}$. In working out questions in 'combinations' advantage is often taken of the fact that, whatever number of elements be *taken* from a group to form a combination, the number *left* gives the same number of combinations; thus, the number of combinations of 10 elements *three* together, is the same as that of 10 elements *seven* together.

Pernambu'co, or RECIFE, the busiest seaport of north Brazil, stands at the easternmost point of the coast, in 8° 3′ S. lat. It consists of three portions, connected by bridges—*Recife* ('the reef') proper, a Dutch-looking quarter, with narrow, winding streets, the chief seat of commerce, on a peninsula; *San Antonio*, a modern quarter, with straight, wide streets, on an island between the peninsula and the mainland; and *Boa Vista*, where are the merchants' villas, on the mainland. The principal buildings and public institutions embrace two arsenals, an observatory, the palace of the Bishop of Olinda (8 miles to the north), a law school, &c. The harbour is formed by a reef lying a quarter to half a mile from the coast, with an opening for vessels drawing 19 feet of water. Since 1890 something has been done towards the deepening of the harbour, the construction of additional quays, docks, and a new breakwater. But still mail-steamers load and unload by means of lighters from the outer (exposed) roadstead. Cottons, machinery, and tobacco are manufactured, and shipbuilding is carried on. There is a lighthouse in the harbour, which is defended by forts. The principal exports are sugar and cotton, with rum, hides, dye-woods, &c.; the principal imports are cottons and woollens, fish and meat, vegetables, minerals, wines, &c. The former fluctuate in value between about £1,500,000 and nearly four times that sum, the fluctuations depending upon the sugar and cotton crops; the imports average from one to two millions sterling. England, the United States, and France have the largest shares in this trade, England supplying about one-half of the imports and taking between one-half and one-third of the exports. Pop. (1878) 94,493; (1898, an estimate) 190,000. Recife was founded by the Spaniards in the second half of the 16th century. Sir James Lancaster captured it in 1595, and the Dutch in 1630. The other two quarters, Mauritsstad (now San Antonio) and Schoonzigt (Boa Vista), were laid out by the Dutch Count Maurice in 1639. The Portuguese captured the town in 1654. — The *province* has a hot, moist climate; produces sugar and cotton; and has an area of 49,625 sq. m. and a pop. of (1872) 841,539; (1898) 1,110,831. Large portions of the interior still remain in a state of nature, uncultivated and covered with forests.

Pernambuco Wood. See BRAZIL-WOOD.

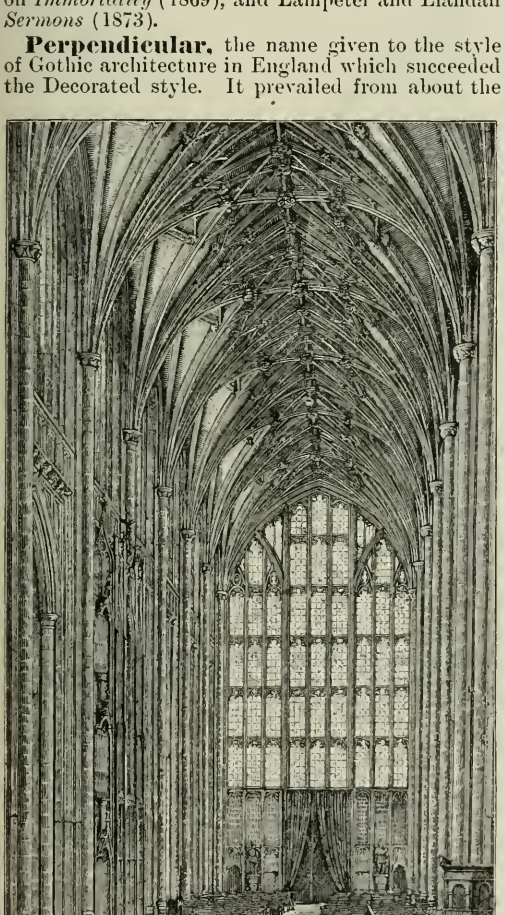
Pernow (Ger. *Pernau*), a seaport of the Baltic Provinces of Russia, stands at the mouth of the river Pernow, at the northern extremity of the Gulf of Riga, 100 miles N. of Riga and 80 W. of Dorpat. Besides linseed and barley, it ships large quantities of flax, principally to Great Britain. The total exports average £526,000 per annum (£423,000 for flax); the imports (herrings, coal, and chemical manure) only some £6500. Pop. 12,918. The university of Dorpat was stationed here from 1699 to 1710.

Pérouse. See LA PÉROUSE.

Perowne, JOHN JAMES STEWART, was born at Burdwan in Bengal, March 13, 1823, of a family of Huguenot origin. He had his education at Norwich grammar-school and at Corpus Christi College, Cambridge, carried off many prizes for theological knowledge and Hebrew, besides the Member's

Latin essay, graduated B.A. in 1845, and was elected Fellow of his college in 1849. He was afterwards examiner for the classical tripos, select preacher, Hulsean lecturer (1868), and Lady Margaret's preacher; professor in King's College, London; and from 1862 till 1872 vice-principal of St David's College, Lampeter. Later he was prelector in Theology and Fellow of Trinity College, Cambridge; preacher at the Chapel Royal, Whitehall; and canon residentiary of Llandaff from 1869 to 1878, when he was appointed Dean of Peterborough. Already, since 1875, he had been also Hulsean professor of Divinity at Cambridge, and an honorary chaplain to the Queen. In 1891 he succeeded Dr Philpott as Bishop of Worcester. Dr Perowne is a sound Hebrew scholar, sat throughout in the Company for the revision of the Old Testament, and has been general editor of the admirable series of short commentaries forming 'The Cambridge Bible for Schools.' His principal work is his commentary on the *Book of Psalms* (2 vols. 1864–68), a masterpiece of exegetical science. Besides sermons and contributions to magazines, other works are his Hulsean Lectures on *Immortality* (1869), and Lampeter and Llandaff *Sermons* (1873).

Perpendicular, the name given to the style of Gothic architecture in England which succeeded the Decorated style. It prevailed from about the



Winchester Cathedral—Nave, looking west.

end of the 14th century to the middle of the 16th century, and was thus contemporary with the Flamboyant style in France. These styles have much in common, but they derive their names from the features peculiar to each. Thus, the Flamboyant (q.v.) is distinguished by the flowing lines of its tracery; whilst the Perpendicular is remarkable for its stiff and rectilinear lines. The lines of the window-tracery are chiefly vertical, and the mullions are frequently crossed by transoms or horizontal bars. The mouldings are usually thin and hard. The same feeling pervades the other features of the style; the buttresses, piers, towers, &c. are all drawn up and attenuated, and present in their shallow recesses and meagre lines a great contrast to the deep shadows and bold mouldings of the earlier styles. The art of masonry was well understood during the Perpendicular period, and the vaulting was admirably built. Fan-tracery Vaulting (q.v.) belongs to this style. The depressed or four-centre arch is another of its peculiar features. In doorways the arched head is frequently enclosed in a square panel over the arch, with spandrels containing shields, quatrefoils, &c. Panelling was also much used, the walls being frequently almost entirely covered with it, as in Henry VII.'s Chapel at Westminster. There are many well-known buildings of this style. Most of the colleges at Oxford and Cambridge belong to it, and in almost every cathedral and church of importance there are some specimens of it—e.g. William of Wykeham's nave at Winchester (q.v.). Open timber-roofs are very common in the Perpendicular style, and are amongst the peculiar and beautiful features of the architecture of England. The roof of Westminster Hall, built by Richard II., is the largest example ever erected.

Perpetual Cure. See CURATE, VICAR.

Perpetual Motion. Formerly the attempts made to 'square the circle' led to an enormous waste of time till mathematicians proved, by repeated and unassailable methods, that the circular area cannot possibly be expressed in terms of the diameter or radius. It logically follows from the definition of a circle that it is a plane figure which does not admit of being squared. In the same way, to all who have understood the words *force* and *motion*, it follows from the definition of a machine that it does not admit of being 'perpetual,' or self-moved. Every machine is constructed to transmit motion or force. The machine, further, modifies the transmitted force, so as to overcome certain resistances, some 'useful' and some 'prejudicial.' In every instance the motion of the machine is derived from without, and the energy so conveyed is to be at once referred to muscular action, or the weight of falling water, or a current of air, or the expansive force of steam, or some other natural power. Some such force is at once implied by the action of any machine, whether the motion is only commencing or has continued for an indefinite time. In an ordinary clock, for example, action is due to the muscular force expended in coiling a spring or raising a weight. The sight of motion in wheels or levers compels us to believe that force has been exerted upon them, and that they are merely vehicles for transmitting it. The machine has gained so much motion and energy, but only at the expense of some exterior agent. The quantity of force in existence being fixed, no new stock can be created, and therefore a self-moving machine is absurd even in name. The practical engineer knows that the force of his steam-engine is exactly in proportion to the amount of coal burned per hour—i.e. the work depends on the consumption of heat. If the mechanical force produced is in excess, however small, of its equivalent (measured by the coal burned), then perpetual motion would be at last found, because then the engine would be generating force—i.e.

giving out more than was derived from the heat of the coal. This, of course, is impossible; it is from the inexhaustible stores of nature alone, such as fire, water, wind, chemical action, and electricity, that force is derived to give motion to any machine whatever. Instead of producing more force than it has received, and so laying up a stock of energy which might render it 'perpetual,' every machine must in its results show less energy than has been transmitted to it. Some of the machine's work is always spent on friction and the atmospheric resistance, so that it cannot give out all the force that was put in.

A 'simple pendulum' swinging in an exhausted receiver, or a top spinning there, might illustrate the term Perpetual Motion, if friction could be avoided. Neither of these, however, could be called a perpetual machine. Give the top some work to do by putting it in gear, say, with a wheel or a crank, and speedily its motion slackens; which proves that, for a 'machine,' new force is constantly required from without, especially if anything more than mere motion is required. In the words of the French Academy (*Histoire*, 1775): 'Neglecting friction and resistance (of the air), a body to which motion has been given will retain it for ever, but only on condition that it does not act on other bodies; and the only perpetual motion possible, even on this hypothesis, would be useless for the purpose of the devisers. . . . Numerous mechanics who might have been of great service have wasted (on this kind of research) their means, time, and talents.'

The mere enumeration of all the chief attempts made in various countries to contrive a self-moving machine would be tedious. We shall only note some typical cases in each class. In one class of so-called perpetual machines the essential part was a wheel revolving on a horizontal axis, with several movable weights so distributed round the rim as apparently to act always more on one side than the other, and thus continue the revolution. One of these was by the ingenious Marquis of Worcester, and is described in his *Century of Inventions* as having been tried in the Tower before the king and court. On the same principle was Jackson's machine shown in fig. 1. In other attempts of this class the side of the wheel was divided symmetrically into cells with curved sides, each cell holding a ball which rolled about as the

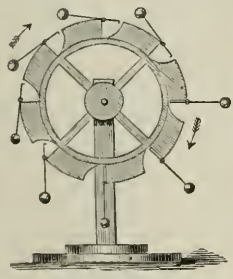


Fig. 1.

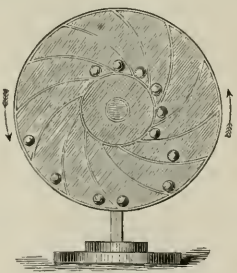

Fig. 2.

revolution took place, so that the balls should, by being further from the centre, act more on one side than on the other, as shown in fig. 2. A foreign instance, described in a letter to Newton as an undoubted success, was that of Orffyreus, consisting of a large wheel covered with canvas. When set in motion the speed increased till it reached a rate of twenty-five revolutions a minute; and when sealed up by the Elector of Cassel it was found at the end of two months to be moving as rapidly as ever. We must of course assume the existence of some imposition in this and more recent cases.

In another class of self-moving machines water or mercury became the prime motor, and was sometimes used in defiance of the most elementary laws of hydrostatics. One of these consisted essentially of a large vessel having a curved tube leading from the bottom up one side and bending over the brim. The inventor actually concluded that the great weight of the liquid in the vessel when full, or nearly so, must force the liquid in the tube up higher than the edge of the vessel, and thus cause a perpetual circulation.

Another class depended on magnetic action, such as Bishop Wilkins's inclined plane up which an iron ball was drawn in a groove by the attraction of a loadstone fixed at the top (fig. 3). Before reaching the loadstone the ball was ingeniously intended to fall through a hole in its path on to a curving incline beneath, and thus be conveyed by a second groove to the foot of the first inclined plane, in order to recommence its upward journey under exactly similar circumstances. The bishop overlooked the fact that the magnetic action would also tend to prevent a fall; but for that fallacy, he had come

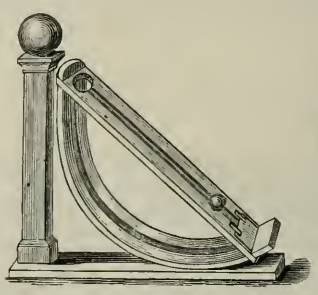

Fig. 3.

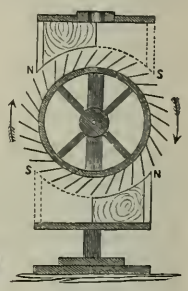

Fig. 4.

as near success as the laws of nature permit. In Addeley's perpetual motion the wheel was surrounded by a set of magnets, projecting like teeth in a slanting direction, and having the S poles all towards the centre (fig. 4). Four larger fixed magnets were disposed outside the wheel, two of which at opposite points of the circumference presented their S poles to attract the revolving magnets, while half-way between them the other two presented their N poles to retard them. All the four magnets, however, acted against the inventor's purpose, as well as in the direction which he intended. In fact, if magnetic action or gravity could be temporarily nullified in a particular direction (as light is by interposing an opaque body) the problem of perpetual motion could immediately be solved.

Innumerable patents have been taken out for magnetic and electric machines, but in the principle of each some fallacy lurks, due to a misconception of the laws of force-transmission. A typical case is an electric machine driven by a gas-engine where the latter is heated by the decomposition of water by the electricity produced; just as if a steam-engine, for example, could be heated by the friction of certain bodies set in motion by itself.

Some intelligent and practical proposals have from time to time been made to utilise the rise and fall of tides as the motive power of machines. These, however, should not be classed, as is sometimes done, under those named 'perpetual,' since the supply of power is obviously derived from a natural source—the moon's attraction combined with the earth's daily rotation. A tide-mill, exactly as a water-mill or wind-mill, is entirely dependent on an outward supply of power, and can in no sense be termed self-moving or 'perpetual.' Ultimately, of course, all the forms of natural energy are to be referred to the sun, the

source of planetary force as well as life, whatever be their modifications. See H. Dircks, *Perpetuum Mobile: Search for Self-motive Power* (2d series, 1861–70).

Perpetuity, in English law, means an arrangement whereby property is tied up—i.e. rendered inalienable—for all time or for a very long period. Testators and settlers have always been tempted by family pride to restrain their successors from parting with settled property, especially land; but the policy of the law requires that owners should be free to dispose of their property, and perpetuities are sternly discouraged. Land was formerly tied up by means of Entails (q.v.) and by the creation of remainders, but these forms of disposition were brought within strict rule. Trusts were then used to evade the rules of common law, but the equity courts gradually evolved a rule that property should not be tied up unless for the lives of persons in being and twenty-one years beyond; any disposition which may possibly postpone the vesting of property beyond that period is void. The rule left a settler free, by selecting the lives of young persons, to tie up his property for eighty or ninety years. Thellusson, a London banker, attempted to create an immense fortune by directing that the income of his property should go on accumulating during the lives of his children, grandchildren, and great-grandchildren, living at the time of his death, and for twenty-one years beyond. This led to the passing of what is called the Thellusson Act in 1800; the act restricts accumulation of income (except for payment of debts, &c.) to a period of twenty-one years from the death of the settler, or some other of the limited periods described in the act. It is to be observed that trusts for public and charitable purposes are not, as a general rule, within the scope of the law against perpetuities. In the United States the rules developed by the English courts have been generally adopted as the basis of the law; several states have legislated on the subject, and in some cases the local law against perpetuities has been made a part of the state constitution.

Perpignan, a town of France, and a fortress of the first rank (dept. Pyrénées-Orientales), stands on the river Têt, 7 miles from the Mediterranean, 40 by rail S. of Narbonne, and 17 from the Spanish frontier. It commands the passes of the Eastern Pyrenees, and is defended on the south by a citadel, which encloses the old castle of the Counts of Roussillon, and by a detached fort. The streets are narrow and the houses of semi-Moorish construction, and show evidences of Spanish influence. The cathedral (begun in 1324), the Moorish-Gothic cloth-hall or bourse (1396), the town-house (1692), the building of the former university (1349–French Revolution), the palace of justice, and a college are the principal public buildings and institutions. Good red wine is made, sheep and silkworms are bred, vegetables and fruit grown, brandy distilled, cloth woven, and corks cut; and there is a good trade in wine, spirits, wool, cork-bark, oil, cloth, and silk. As capital of the former county of Roussillon Perpignan was in the hands of the kings of Aragon from 1172 to its capture by France in 1475; it was restored to Spain in 1493; but Richelieu retook it in 1642, and France has possessed it ever since. Pop. (1891) 27,593.

Perranzabuloe ('Perran in the sands'), a Cornish coast parish, 10 miles N. by W. of Truro. The rude little stone oratory (25 by 12½ feet) of St Piran, who was sent to Cornwall by St Patrick in the 5th century, had been buried in the sands for a thousand years, when it was discovered in 1835; it is probably the earliest ecclesiastical structure in England. Perran Round is a circular enclosure, with seven rows of seats that could seat 2000, in which miracle plays were performed of old. See works by Haslam (1844) and Trelawny (8th ed. 1884).

Perrault, CHARLES, immortal as the author of 'Puss-in-Boots,' 'Cinderella,' and 'Bluebeard,' was born at Paris, January 12, 1628, the youngest of an advocate's four sons. He was sent at nine to the Collége de Beauvais, but quarrelled with his masters, and had the rest of his education left to chance. He studied law fitfully, and took his license at Orleans in 1651, but soon tired of the humdrum routine of the profession, and filled from 1654 till 1664 an easy post under his brother, the Receiver-general of Paris. In 1663 he became a kind of secretary or assistant to Colbert in matters of architecture and art generally, and for twenty years enjoyed a salary, if not his master's friendship throughout, while by his influence he was admitted to the Academy in 1671. His poem, 'Le Siècle de Louis XIV.,' read to the Academy, and Boileau's angry criticisms thereon, opened up the famous and foolish dispute about the relative merits of the ancients and moderns; to the modern cause Perrault contributed his ambitious but poorly argued *Parallèle des Anciens et des Modernes* (4 vols. 1688–96). The same quarrel inspired his *Éloges des Hommes Illustres du Siècle de Louis XIV.* (2 vols. folio, 102 portraits; 1696–1700), the labour of his latest years. He died May 16, 1703. His *Mémoires* appeared in 1769.

All his writings would already have been forgotten but for the happy inspiration which prompted him to publish in 1697 his eight inimitable prose fairy-tales, the *Histoires ou Contes du Temps Passé*, with the title on the frontispiece of 'Contes de Ma Mère L'Oye.' These had already appeared anonymously from 1696 to 1697 in Moetjens' *Recueil*, a little miscellany published at the Hague since 1694. The same volume contained a reprint of three tales in verse by Perrault (*Peau d'Ane*, *Les Souhaits Ridicules*, and *Griselidis*), which had already appeared both in Moetjens' *Recueil* and in small volumes at Paris in 1694–95. The prose *contes*, on the other hand, were expressly stated to be by P. Darmancour, Perrault's little boy, to whom the 'Privilége du Roy' is granted. M. Paul Lacroix attributes the complete authorship to the son; it is more reasonable to believe with Andrew Lang that, if the naïveté and popular traditional manner point to the conservatism of the child and the native inspiration of his nurse, many a happy touch is due to the elderly academician and wit. But whatever the method of composition of these tales, the resultant is a group of masterpieces in the most difficult of arts, the same judgment of which is renewed generation after generation. It were impertinence to praise these stories; it is enough to enumerate their names: 'La Belle au Bois Dormant' (The Sleeping Beauty); 'Le Petit Chaperon Rouge' (Little Red Riding Hood); 'La Barbe Bleue' (Bluebeard); 'Le Maistre Chat, ou le Chat Botté' (Puss-in-Boots); 'Les Fées' (The Fairy); 'Cendrillon, ou la Petite Pantoufle de Verre' (Cinderella); 'Riquet à la Houppe' (Riquet of the Tuft); and 'Le Petit Poucet' (Hop o' my Thumb, Tom Thumb).

There are editions of the tales by Giraud (Lyons, 1865), Lefèvre (Paris, 1875), Paul Lacroix (Jouast, Paris, 1876), and Andrew Lang (Clar. Press, Oxford, 1888). The last has an exhaustive Introduction of 115 pages. See also Charles Deulin's *Contes de Ma Mère l'Oye avant Charles Perrault* (Paris, 1879); and Deschanel's *Boileau, Charles Perrault, &c.* (Paris, 1888).

Perry, an agreeable beverage made by fermenting the juice of pears. It is extensively made in Worcestershire, Gloucestershire, Herefordshire, and Devonshire, and forms, with cider, the chief

diet-drink of those districts. It contains from 5 to 9 per cent. of alcohol. See CIDER.

Perry, OLIVER HAZARD, an American naval officer, born at South Kingston, Rhode Island, 23d August 1785, is famous for his defeat of a British force on Lake Erie in 1813. Perry, who had nine vessels, with 54 guns and 492 officers and men, fought six vessels, with 63 guns and 502 officers and men, lost four-fifths of the crew of his flagship, and finally won a complete victory, which he announced in the brief despatch: 'We have met the enemy, and they are ours—two ships, two brigs, one schooner, and one sloop.' Perry died of yellow fever at Trinidad, 23d August 1819, and was buried at Newport, Rhode Island, where there is a bronze statue (1885). See Life by A. S. Mackenzie (2 vols. New York, 1843), and in Fenimore Cooper's *Lives of Distinguished American Naval Officers* (1846).

Perryville, a village of Kentucky, about 40 miles SW. of Lexington, was the scene of a hard-fought battle between the Union and Confederate armies of Buell and Bragg, 8th October 1862.

Persecution. The principles that underlie the persecution of obnoxious opinions, as opposed to the principles of toleration, are regarded by those who persecute as essentially similar to those that arm justice against the criminal. Persecution of unpopular religious views has on religious or political grounds been especially common. The persecutions of the early Christians by the Roman emperors (see CHURCH HISTORY) have been usually, though artificially, counted as ten, viz. under Nero, 64 A.D.; Domitian, 95; Trajan, 107; Hadrian, 125; Marcus Aurelius, 165; Septimius Severus, 202; Maximinus, 235; Decius, 249; Valerianus, 257; Diocletian, 303. Some of the best of the emperors were thus the most strenuous persecutors of the Christians. The persecution seemed in many cases but to fan the zeal of the victims and survivors; in Tertullian's words, the blood of the martyrs was the seed of the church. But there have been many cases in which minor sects have been extinguished, partly or wholly by systematic persecution. The orthodox persecuted the Arians not without success; and the number of Lapsed (q.v.) raised a serious problem in the church. Cathari and Albigenses were practically persecuted out of existence by the Dominicans and the Inquisition; and the measures adopted to suppress the Reformation were triumphant in Bohemia, Spain, and Italy. In the Huguenot wars religion was complicated with politics (see BARTHOLOMEW, ST); the Dragonnades (q.v.) were part of a deliberate attempt to crush out Protestantism. The name persecution is used in England specially for the sufferings inflicted by Catholics on Protestants and by Protestants on Catholics in Mary's and Elizabeth's reigns; in Scotland also on the measures used against the Covenanters and other recusants in the 17th century. The oppressive legislation against Independents in Charles II.'s reign may also be classed under this head; and Massachusetts and most of the Puritan colonies passed several repressive measures against the Quakers. The persecutions carried on in the Netherlands by the Spanish authorities (see HOLLAND) were especially cruel and persistent. They comprised fine, imprisonment, ban, torture, beheading, strangling, strangling and burning, burning alive, burying alive; and their continuance goaded the people into a great national revolt. It deserves to be noted that the strenuous denunciation by Voltaire of the persecution of the unfortunate Calas (q.v.) family led to a new chapter in the history of toleration. Furious persecutions extirpated Catholicism from Japan in the middle of the 17th century, and Corea in the middle of the 19th. The Orthodox Eastern Church has in Russia had the assistance of the state in repressing the Raskolnik sectaries. Luther and Melanchthon were more pronouncedly hostile to the heretical astronomy of Copernicus than the Catholic authorities. A notable case of the persecution of a Protestant by Protestants is that of Servetus (q.v.; see also CALVIN). In this case Calvin had the sympathetic support of many foreign Protestant churches and their leaders. The 'theocratic' system established in Geneva by Calvin so confounded errors, sins, and crimes as to turn the administration of justice largely into a persecuting organisation; in three years there were fifty-eight sentences of death, and over eight thousand imprisonments for the crime of blasphemy (see Hug and Stead, *Switzerland*, 1891). The old Scottish discipline of the kirk-session was regarded as persecuting in spirit long ere it ceased to be rigorously applied. The persecutions of the Jews were especially persistent and especially unsuccessful, and have recurred in recent years in Russia, Roumania, and elsewhere.

From the same causes as persecution come much other bloodshed and strife, war and devastation, social oppression, and personal suffering. Metaphysical principles formed the watchwords of political as well as of ecclesiastical parties. 'These evils mostly came from that which has been a permanently disastrous fact in Christian history—the interference of the state, which gave the decrees of the councils that sanction which elevated the resolutions of the majority upon the deepest subjects of human speculation to the factitious rank of laws which must be accepted on pain of forfeiture, banishment, or death' (Hatch, *Hibbert Lectures*, 1888).

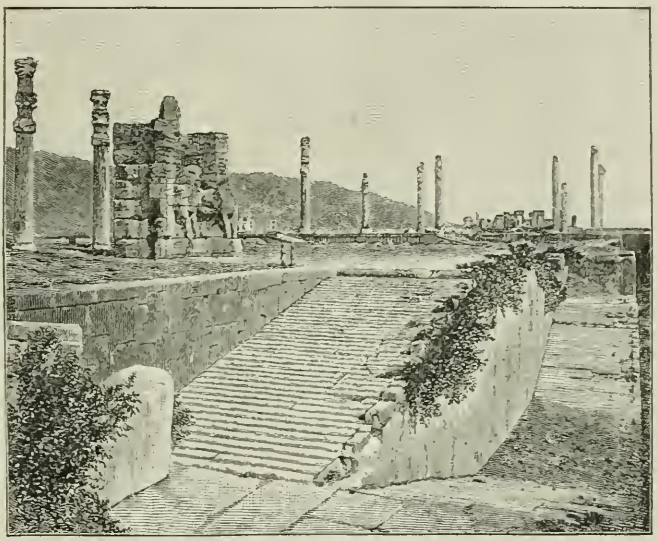
See also the articles named above, especially INQUISITION and TOLERATION; also ALBIGENSES, AUTO DA FÉ, BLASPHEMY, BRUNO, CAMISARDS, CATHOLIC EMANCIPATION, GALILEO, HERESY, HUGUENOTS, MORMONS, WALDENSES, WITCHCRAFT; such works as Foxe's *Book of Martyrs* on one side, and on the other Challoner's *Memoirs of Missionary Priests and other Catholics who suffered Death for Religion*; Buckle's *History of Civilisation*; Lecky's *Rationalism in Europe*; and Draper's *Conflict between Science and Religion*.

Perseids. See METEORS, Vol. VII. p. 158.

Persephone. See PROSERPINE.

Persep'olis ('Persian City'), the Greek translation of the lost name (*Parsa-Karta?*) of the capital of ancient Persia, was situated to the east of the river Medus (Polwar—i.e. Murghab), about 14 miles above its confluence with the Araxes (Bendemir), in the plain of Merdusht, about 35 miles to the north-east of Shiraz, on the road to Ispahan. A series of most remarkable ruins is all that now remains of that city, with which, according to ancient writers, 'no other city could be compared either in beauty or in wealth,' and which was generally designated 'The Glory of the East.' Darius Hystaspes, Xerxes, Artaxerxes, and other Achæmenides each in his turn contributed towards its aggrandisement. Alexander the Great in his march of conquest is said to have destroyed Persepolis completely; but this must probably only be understood to apply to some of the chief palaces. It may also be presumed that after the fall of the Achæmenides the extension of the original town (afterwards known as Istakhr), on which were situated the royal edifices and the temples used as royal treasuries up to the time of Epiphanes, gradually fell into decay. The situation of these structures, overlooking the vast luxuriant plain of Merdusht, is described in terms of rapturous enthusiasm by every traveller from Chardin to our own day. Three groups are chiefly distinguishable in the vast ruins existing on the spot. First, the Chehel-Minár (Forty Pillars),

with the Mountain of the Tombs (Rachmed), also called Takht-i-Jamshíd or the throne of Jamshíd, after a fabulous king, the reputed founder of Persepolis. The next in order is Naksh-i-Rustam, to the north-west, with its tombs; and the last, the building called the Haram of Jamshíd. The most important is the first group, situated on a vast terrace of cyclopean masonry at the foot of a lofty mountain-range. The extent of this terrace is about 1500 feet north by south and about 800 east by west, and it was, according to Diodorus Siculus, once surrounded by a triple wall of 16, 32, and 60 cubits respectively in height. The whole internal area is further divided into three terraces —the lowest towards the south; the central being 800 feet square and rising 45 feet above the plain, and the third, the northern, about 550 feet long and 35 feet high. No traces of structures are to be found on the lowest platform; on the northern, only the so-called 'Propylæa' of Xerxes; but the central platform seems to have been occupied by the foremost structures, which again, however, do not all appear to have stood on the same level. There are distinguished here the so-called 'Great Hall of Xerxes' (called Chehel-Minár by way of eminence), the Palace of Xerxes, and the Palace of Darius. The stone used for the buildings is dark gray marble, cut into gigantic square blocks, and in many cases exquisitely polished. The ascent from the plain to the great northern platform is formed by two double flights, the steps of which are nearly 22 feet wide, 3½ inches high, and 15 inches in the tread, so that many travellers have been able to ascend them on horseback. What are called the Propylæa of Xerxes on this platform are two masses of stone-work, which probably formed an entrance-gateway for foot-passengers, paved with gigantic slabs of polished marble. Portals still standing bear figures of animals 15 feet high, closely resembling the Assyrian bulls of Nineveh. The building itself, conjectured to have been a hall 82 feet square, is, according to the cuneiform inscriptions still extant, the work of Xerxes.



Great Staircase to Northern Platform, and Propylæa of Xerxes; Great Hall of Xerxes and Palace of Darius in the distance.

An expanse of 162 feet divides this platform from the central one, which still bears many of those columns of the Hall of Xerxes from which the ruins have taken their name. The staircase leading up to the Chehel-Minár or Forty Pillars is, if possible, still more magnificent than the first; and the walls are more superbly decorated with sculptures, representing colossal warriors with spears, gigantic bulls, combats with wild beasts, processions, and the like; while broken capitals, shafts, pillars, and countless fragments of buildings, with cuneiform inscriptions, cover the whole vast space of this platform, 350 feet from north to south and 380 from east to west. The Great Hall of Xerxes, perhaps the largest and most magnificent structure the world has ever seen, is computed to have been a rectangle of about 300 to 350 feet, and to have consequently covered 105,000 square feet or 2½ acres. The pillars were arranged in four divisions, consisting of a centre group six deep every way, and an advance body of twelve in two ranks, the same number flanking the centre. Fifteen columns are all that now remain of the number. Their form is very beautiful. Their height is 60 feet, the circumference of the shaft 16, the length from the capital to the torus 44 feet. The shaft is finely fluted in fifty-two divisions; at its lower extremity begin a cincture and a torus, the first 2 inches in depth and the latter 1 foot, from whence devolves the pedestal, shaped like the cup and leaves of the pendent lotus, the capitals having been surmounted by the double semi-bull. Behind the Hall of Xerxes was the so-called Hall of Hundred Columns, to the south of which are indications of another structure, which Fergusson terms the Central Edifice. Next along the west front stood the Palace of Darius, and to the south the Palace of Xerxes, measuring about 86 feet square, similarly decorated and of similar grand proportions.

For a more minute description, see the travels of Niebuhr, Ker Porter, Rich, &c.; Fergusson's *Palaces of Nineveh and Persepolis Restored*, Vaux's *Nineveh and Persepolis*, Rawlinson's *Five Great Monarchies*, Madame Dieulafoy's *La Perse et La Susiane*, M. Dieulafoy's *L'Art Antique de la Perse*, and above all, for detailed photographic views, *Persepolis*, by F. Stolze and Th. Noldeke (Berlin, 1882). See also CYRUS, DARIUS, XERXES, CUNEIFORM, and PERSIAN ARCHITECTURE.

Perseus, in Greek Mythology, the son of Zeus and Danaë (q.v.) and grandson of Acrisius. He was brought up at Seriphos, one of the Cyclades, where Polydectes reigned, who, wishing for private reasons to get rid of him, sent him when yet a youth to bring the head of the Gorgon Medusa, on the pretence that he wanted to present it as a bridal gift to Hippodamia. Perseus set forth under the protection of Athena and Hermes, the former of whom gave him a mirror by which he could see the monster without looking at her (for that would have changed him into stone), the latter a sickle, while the nymphs provided him with winged sandals and a helmet of Hades or invisible cap. After numerous wonderful adventures he reached the abode of Medusa, who dwelt near Tartessus, on the coast of the ocean, and succeeded in cutting off her head, which he put into a bag and carried off. On his return he visited Ethiopia, where he liberated and married Andromeda (q.v.), by whom he subsequently had a numerous family, and arrived at Seriphos in time to rescue his mother from the

annoyance of the too ardent addresses of Polydectes, whom, along with some of his companions, he changed into stone. After this he went to Argos, from which Acrisius fled to Thessaly, and Perseus assumed the vacant throne. But this, like many other details of the myth, is differently narrated. Perseus was worshipped as a hero in various parts of Greece, and, according to Herodotus, in Egypt too. In ancient works of art the figure of Perseus much resembles that of Hermes.

Perseverance of Saints, a doctrine necessarily resulting from the most essential part of the Calvinistic system, and therefore held by almost all who adopt the Calvinistic or Augustinian doctrines. It is advocated not only by arguments from other doctrines, as those of election, atonement, the intercession and mediatorial dominion of Christ, imputed righteousness, and regeneration, but also from many texts of Scripture, as those which declare eternal life to be always connected with believing, and those which encourage the believer to depend on the faithfulness, love, and omnipotence of God. To an objection very commonly urged against it, that it tends to make men careless concerning virtue and holiness, its advocates reply that this objection is valid only against a doctrine very different from theirs, the true doctrine of Perseverance of Saints being one of perseverance in holiness, and giving no encouragement to a confidence of final salvation which is not connected with a present and even an increasing holiness.

Pershore, a pleasant, old-fashioned market-town of Worcestershire, in a great fruit-growing district, on the Avon, 9 miles SE. of Worcester. Holy Cross, the church of a mitred Benedictine abbey, originally founded in 689, is but a fragment—choir, south transept, and central tower, mainly Decorated in style, but with Norman and Early English features. It was restored by Scott in 1863–65. Pershore has manufactures of stockings and agricultural implements. Pop. (1851) 2717; (1881) 2885; (1891) 2708. See Styles's *History of Pershore Abbey Church* (1838).

Persia, called by the natives Iran (see Aryan Race), the most extensive and powerful native kingdom of western Asia, is bounded on the N. by the Transcaspian provinces of Russia, the Caspian Sea, and the Transcaucasian provinces of Russia; on the E. by the Transcaspian provinces of Russia, Afghanistan, and Beluchistan; on the S. by the Strait of Ormuz and the Persian Gulf; and on the W. by Asiatic Turkey. It extends 900 miles from east to west and 700 miles from north to south, and has an area of about 638,000 sq. m. It consists for the most part of a great tableland or elevated plateau, which in the centre and on the east side is almost a dead level, but on the north, west, and south is covered with mountain-chains. The provinces of Azerbijan, Mazanderan, Ghilan, Kurdistan, Luristan, and Fars are almost wholly mountainous. From the southern boundary of Azerbijan the majestic range of the Elburz runs eastward, following the line of the Caspian coast at a distance varying from 12 to 60 miles. On reaching Astrabad the mountains sink into ridges of lower elevation, one of which joins the Paropamisus in Afghanistan. A hill-country lies north of this line: it terminates in the Daman-i-koh chain, which sinks abruptly to the low plain of Turkestan. South and east of Azerbijan a broad mountain-belt traverses Persia from north-west to south-east, the chains and valleys of which it consists lying in the same direction. To this region belong the mountains running from Hamadan to Shiraz, some of the peaks of which are clad with perpetual snow, and the Zagros Mountains and Pushti Kuh on the western frontier. The Persian mountains are mostly primitive; granite, porphyry, felspar, and mountain-limestone enter largely into their composition. They also exhibit indications of volcanic action, Demavend, a conical peak 18,600 feet in height, the highest summit connected with the Elburz range (or ranges), being an extinct volcano; and earthquakes occasionally occur. The Persian plateau, which lies in an angle formed between these mountains, is intersected by many subsidiary ranges and groups of mountains, and spreads eastward to the plateau of Afghanistan, its general elevation ranging from 2000 to 5000 feet above sea-level, the lowest portion being the Great Salt Desert in the south-west of Khorassan, which has 2000 feet of elevation above the sea; while the average elevation of the whole plateau above the sea is about 3700 feet. See Asia.

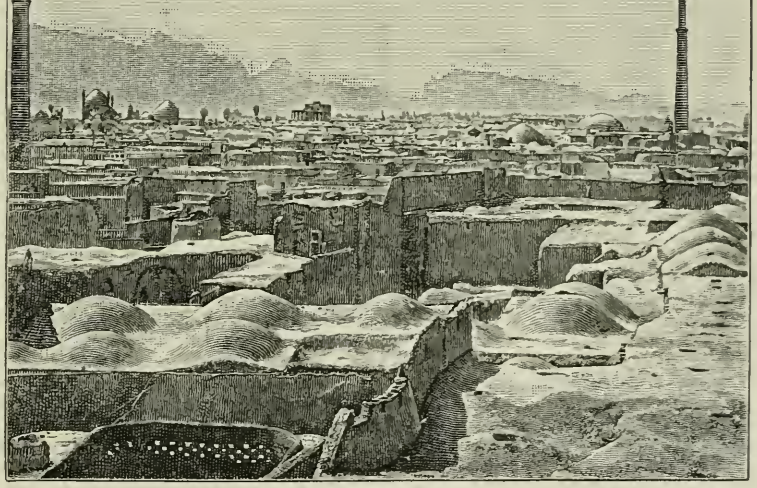
A great part of Khorassan, the north half of Kerman, the east of Irak-Ajemi, which form the great central plain, and detached portions of all the other provinces, with the exception of those on the Caspian Sea, forming more than three-fourths of the surface of Persia, are desert—that is to say, are uncultivated owing to the want of rain and of artificial irrigation. In some parts of this waste the surface produces a scanty herbage of saline plants; in other parts, called *Kevir*, it is covered with an efflorescence of saltpetre, which glitters and flashes in the sunlight, forcing the traveller on these inhospitable wastes to wear a shade to protect his eyes; but by far the greater portion of this region consists of light dry soil, which only requires irrigation to become fruitful. This great central desert contains a few oases, but none of great extent. A narrow strip of low and level country extends along the shores of the Persian Gulf and the Strait of Ormuz. It consists of a succession of bare plains, occasionally interrupted by a plantation of palms near the scanty rivulets which traverse it. It is called Dushtistan, or by the generic name, applied to many other localities, of *Garmisir*—i.e. the warm region, in opposition to the mountainous districts, called *Sarhad*, or the cold country.

Although so much of Persia is desert, some parts of the country are of exceeding fertility and beauty; the immense valleys, some of them 100 miles in length, between the various ranges of the Kerman Mountains abound with the rarest and most valuable vegetable productions. Great portions of the provinces of Fars, Khuzistan, Ardelan, and Azerbijan have been lavishly endowed by nature with the most luxuriant vegetation; while the provinces of Ghilan and Mazanderan, which lie between the Elburz and the Caspian Sea, and the southern slopes of the Elburz are as beautiful as wood, water, and a moderately hot climate can make them—the mountain-sides being clothed with trees and shrubs, and the plain, 300 miles long by from 5 to 30 miles wide, studded with mulberry plantations, rice-fields, vineyards, orchards, orange grounds, and sugar and cotton plantations.

Rivers and Lakes.—Persia has hardly one river that can properly be termed navigable, though some of them are several hundred miles in length, and of great width and volume of water. The Karun (q.v.) was opened to foreign steam-navigation from its mouth to Ahwaz (where there is a series of rapids) in 1889. The rivers which flow to the southward receive in the latter part of their course few tributaries, and fertilise only a narrow strip of land on each side of them, except when their waters are applied, by means of canals or other works, to the artificial irrigation of the soil. Most of the monuments of the architectural skill

and laborious industry of the ancient Persians in this department are now ruinous. As a natural consequence of the nature and situation of its surface, Persia abounds with saline lakes, and there are nearly thirty of them having no visible outlets. The chief lake is Lake Urumiah (q.v.), in Azerbijan. Lake Bakhtegan, in the east of Fars, the receptacle for the drainage of the northern half of that province, is about 60 English miles in length by 9 in breadth. Lake Shiraz is much smaller. Part of Lake Zirreh is included in the frontier of Persia.

Climate and Products.—The climate is necessarily very varied. What the younger Cyrus is reported to have said to Xenophon regarding the climate, 'that people perish with cold at one extremity of the country, while they are suffocated with heat at the other,' is literally true. Persia may be considered to possess three climates—that of the southern Dashtistan, of the elevated plateau, and of the Caspian provinces. In the Dashtistan the autumnal heats are excessive, those of summer more tolerable, while in winter and spring the climate is delightful. On the plateau the climate of Fars is temperate. About Ispahan the winters and summers are equally mild, and the regularity of the seasons appears remarkable to a stranger. To the north and north-west of this the winters are severe. The desert-region of the centre and east, and the country on its border, endure most oppressive heat during summer and piercing cold in winter. The Caspian provinces, from their general depression below the sea-level, are exposed to a degree of heat in summer almost equal to that of the West Indies, and their winters are mild. Rains, however, are frequent and heavy, and many tracts of low country are marshy and extremely unhealthy. Except in the Caspian provinces, the atmosphere of Persia is remarkable above that of all other countries for its dryness and purity.



Ispahan, looking south.

The cultivated portions of Persia, when supplied with moisture, are very fertile, producing an immense variety of crops. The chief cultivated products are wheat (the best in the world), barley, and other cereals, cotton, sugar and rice (in Mazanderan), and *tumbaku* or tobacco for the *narghileh* or water pipe. The vine flourishes in several provinces, and the wines of Shiraz are celebrated in eastern poetry. Mulberries are also largely cultivated, and silk is one of the most important products of the kingdom. Owing, however, to the silkworm disease and the neglect of the Persian government to procure healthy *grain* from abroad, the silk cultivation has of late years greatly diminished.

The forests of the Elburz abound with wild animals, as wolves, tigers, jackals, boars, buffaloes, foxes, and the Caspian cat. Leopards abound in Mazanderan, and lions in parts of Fars and Arabistan. Among domestic animals the horse, the ass, and the camel hold the first place. The horses have always been celebrated as the finest in the East. They are larger and more handsome, but less fleet than the Arabian horses. The Caspian rivers abound with fish, especially sturgeon, great quantities of which are cured and exported to Russia. The mineral products of Persia are insignificant, with the sole exception of salt. Iron is abundant in Azerbijan, but is not worked; copper occurs in considerable quantity in the mountains of Mazanderan and Kerman; and lead, antimony, sulphur, and naphtha also abound. Long before Dr Tietze's report (1874) coal had been successfully worked in the mountains near Teheran.

Inhabitants.—The settled population are chiefly Tajiks, the descendants of the ancient Persian race, with an intermixture of foreign blood. To this class belong the agriculturists, merchants, artisans, &c. The Tajiks are Mohammedans of the Shiite sect, with the exception of the remaining Parsees (some 9000 in number), who are found chiefly at Yezd, and still retain their purity of race and religious faith. The Tajiks have been spoken of as timid, cunning, and servile, but Vambéry testifies to their industry, and their capacity for and love of culture. The nomad or pastoral tribes, or eylats (*eyl*, 'a clan'), often spelt *illyats*, are of four distinct races—Turks (not Osmanli Turk), Kurds, Lúurs, and Arabs. Their organisation is very similar to that which formerly subsisted among the Highland clans of Scotland, with the exception that the former are nomad, while the latter inhabited a fixed locality. Each tribe is ruled by its hereditary chief (*ujak*), and under him by the heads of the cadet branches (*tirehs*) of his family. Of the four nomad races the Turk is the most numerous, and to it belongs the present Kajar dynasty. The Kurds are few in number, the greater part of their country and race being under the sway of Turkey. The Arabs are also few in number, and at the present day can hardly be distinguished from the Persians, having adopted both their manners and language. The Lúurs are of nearly pure Persian blood. The nomad races are distinguished from the Tajiks by their courage, manliness, and independence of character; but they are inveterate robbers, and have been the cause of many civil wars and revolutions. There is a small population of native Christians—the Nestorians of Urumiah and Telmais, and Armenians, whose principal settlement is at Julfa (Ispahan), where there is an archbishop and a

cathedral. Including those who have joined the Roman Catholic and Protestant churches, the whole number of Christians can hardly exceed 50,000. The Jews number 15,000.

We have no certain information regarding the population of Persia. There can be no doubt that in antiquity, and even during the middle ages, while the irrigation-works still fertilised great tracts of country, it supported a great population. In the 17th century the French traveller, Chardin, thought 40 millions not too high a figure. Recent travellers, however, reduced these sums to numbers varying from 15 to 8 millions. Much surprise was accordingly expressed when in 1868 Sir Ronald Thomson reported that the entire population did not exceed 5 millions, and was probably not over 4 millions. His estimate has since been generally accepted as the most trustworthy we have, although the official estimate in 1881 was 7,653,600. He divides the total roughly into a million inhabitants of cities, 1,700,000 nomads, and 1,700,000 peasants and villagers; and the following are his estimates of the population of the chief cities: Tabriz, 110,000; Teheran, 85,000; Meshhed, 70,000; Ispahan, 60,000; Yezd, 40,000; Kerman, 30,000; Kermanshah, 30,000; Hamadan, 30,000. Teheran has largely increased since this estimate was made, and in 1891 was said to have 210,000 inhabitants. There can be no doubt that the population of Persia has been long diminishing, a fact attributable to misrule and extortion, neglect of the great irrigation-works, and the frequent occurrence of famines in a dry country where cultivation depends on an artificial supply of water.

The roads are utterly neglected. The houses, those of the wealthiest people not excepted, appear contemptible, being generally built of earth or mud, and are grouped, even in the towns, with little attention to uniformity or order. They scarcely ever exceed one story in height, and they are surrounded by high blank walls. The public buildings, such as mosques, colleges, and caravanserais, are of similar appearance to the ordinary houses, and built of the same materials. The interiors, however, of the houses of the rich are sometimes perfect paradises of luxury and elegance. The miserable look of the towns is, moreover, greatly redeemed by the beauty of the gardens which surround them.

Manufactures and Trade.—The trade of Persia is comparatively of little importance. The silk used to be the great staple, and is produced in almost every province, but chiefly in Ghilan, Kashan, and Yezd. The repeated failure of the crop has, however, interfered very seriously with this branch of industry. Cotton and woollen fabrics, shawls, carpets, and felts are largely manufactured for use and export in different parts of the country. Trade is carried on by caravans with the interior of Asia and the chief towns of Persia. These caravans exchange the products of Persia for cloth, printed calicoes, shirting, copper sheets, hardware, glass and porcelain, tea, coffee, sugar, candles, paraffin-oil, lucifer matches, and fancy goods. The principal trade centres are Tabriz, Teheran, Ispahan, and Bushire. European goods are brought to Tabriz by Constantinople and Trebizond; to Teheran partly by Tabriz, partly by the Caspian, and partly by Bushire; while to Ispahan they are brought almost exclusively by Bushire. In recent times the communication between Persia and foreign countries has been greatly increased by way of the Caspian owing to the development of the copious petroleum-wells at Baku. By means of the cheap fuel thus obtained the Russian commercial fleet on the Caspian has increased fourfold, and railways have been made from Batoum on the Black Sea to Baku on the Caspian, and from the eastern coast of the Caspian to Askabad, Bokhara, and Samarkand. On the former sea there is a considerable Russian fleet of schooners and screw-steamers. Vessels sail weekly from Astrakhan and bi-weekly from Baku with merchandise for the Persian coast, touching at Enzelli, Mashadisar, and Ashurada. In the Persian Gulf the British India Steam-navigation Company have a regular line of fine steamers running weekly from Bombay to Basra, and touching at Bender-Abbas and Bushire. Fortnightly steamers were started in 1889 by an English firm on the Karun to ply between Mohammerah and Ahwaz in virtue of the concession of free navigation granted by the Shah in 1888. In 1890 Mr Curzon affirmed that in the north-west, north, and north-east districts a decided Russian superiority in trade was met and in parts disputed by British and Indian competition; in the south and west British ascendency is established and is being increased. The exports consist of wheat, rice, wine, raisins, almonds and nuts, olive-oil, tobacco, drugs, gums, resins, manna, opium, colouring matters, boxwood, walnut-wood, silk, wool, carpets, skins and furs, wax, pearls, turquoises, sulphur, naphtha, salt; the chief imports are cotton goods from Britain, and broadcloths, jewellery, arms, cutlery, watches, earthen, glass, metal wares, &c. The whole foreign trade of Persia has been estimated roughly at—imports, £5,300,000; exports, £3,000,000. The imports of British produce into the three ports of Bushire, Lingah, and Bender-Abbas amounted in 1895 to over £370,000, not including Indian trade; while the exports to Britain thence were worth £175,000. In 1890–95 the average value of imports from Russia was £878,000, and of exports to Russia £1,486,000. The export of Persian carpets—of which there are thirty different kinds—amounts to £150,000 a year. Many projects of railways have been formed, but up to 1899 only one of them had been carried out—viz. from Teheran to Shah Abul Azim, a place of pilgrimage distant only 6 miles. Tramways were laid down in Teheran, and an imperial bank established with branches in the other large towns, in 1889.

Government, Taxation, Education, &c.—The government of Persia is a pure despotism, limited only by the power and influence of the Mohammedan mollahs or priests, domestic intrigues, dread of private vengeance, and an occasional insurrection. The first named is the principal check against unjust government on the part of the monarch, while the latter three operate as powerful restraints on his ministers. The monarch, who has the title of 'Shah' and 'Padishah,' possesses absolute authority over the lives and property of his subjects. His deputies, the governors of provinces and districts, possess similar authority over those under them; their actions are, however, liable to revision by the Shah, who may summarily inflict any punishment upon them for real or alleged misgovernment. Oppression of the sedentary agricultural classes is almost a necessity of such a form of government. The central government consists of a ministry, nominally modelled somewhat after the cabinets of European states. Usually, however, the power falls actually, if not nominally, into the hands of one of their number. The Shah, nevertheless, is in reality his own prime-minister, and even trivial matters are submitted for his personal decision. The principal ministers are those for the Interior (practically the head of the government), for Foreign Affairs, for Finance, for War, for Telegraphs, &c., for Justice, and the President of the Council, who is at the same time postmaster-general and general secretary of state. The law both in civil and criminal cases is administered by the governors, who not unfrequently refer

points of law, which is based upon the Koran and its commentaries, to mollahs and mushteheds. The punishments commonly inflicted are fines, flogging (the bastinado), and death, either by decapitation, stabbing, or torture. The principal Hákim or governors of provinces are chosen for the most part from among the members of the royal family. As a rule life and property are much more secure than is generally supposed. The revenue is derived from (1) a tax on the gross produce of land—25 per cent. may be taken as the average assessment; (2) duties on cattle and flocks—in case of goats, sheep, and cows, 8 per cent. on value of wool and butter yielded; (3) customs dues; and (4) duties on provisions brought to market. It will thus be seen that the direct taxation falls almost exclusively on the land and its cultivators. In theory these are the taxes authorised by the government, but in practice a frightful system of bribery and extortion prevails. The wealthy and influential escape the rapacity of the provincial governors, but as much as possible is taken from the hard-working peasants. It is believed that the irregular exactions amount to a sum equal to the legal assessments, and that not a penny of the money so extorted is applied to public purposes. The annual revenue in 1890–97 may be stated at from £1,600,000 to £1,775,000.

Elementary education is very generally diffused among all classes. There are a large number of colleges where students are instructed in religion and Persian and Arabian literature. Among a considerable section of the upper classes it is asserted that the Mohammedan religion is losing its hold, and that unbelief is widely prevalent.

Political Divisions, &c.—From the earliest times down to the present century Persia was divided into seven or eight great divisions; but about the time when it was attempted to introduce European civilisation into the country, and discipline into the army, the country was anew divided into twenty-five provinces. There are many interesting ruins of ancient, populous, and celebrated cities in Persia—e.g. Persepolis (q.v.), and Istakhr, Rhages or Rhé, Shahpur, Tús, Merv, Shushan, Hamadan, &c.

Army.—The standing army, according to the recent army laws, consists of 200,000 men, but the majority of these exist only on paper. The regular army is really composed of about 30,000 infantry and 1000 artillery, while there are about 10,000 irregular cavalry, a few thousand irregular infantry, and the guards. The officers in the Persian army are for the most part ignorant and inefficient, but the soldiers are obedient, sober, intelligent, and capable of enduring great fatigue. The irregular cavalry, which forms the bravest portion of the Persian army, is equal to the Cossacks in the Russian army, and much superior to the Turkish Bashi-Bazouks.

History.—According to the *Shah Nameh* of Firdausi, the history of Persia begins some thousands of years before the Christian era. Little has been done towards extracting the grains of historical truth that may be contained in the mass of fable that constitutes the native Persian annals, and as yet we must rest contented with the accounts derived from Greek writers. The north-western part of Iran, anciently called Media (q.v.), was, at the earliest period known to the Greeks, a part of the Assyrian empire, but the Medes revolted, and in 708 B.C., under Dejoces, established an empire which subdued both that of Assyria and their own kindred tribes of Persis. About 537 the Persians under Cyrus (q.v.)—the Kai-Khusru of the Persians—rebelled, subdued their former masters, the Medes (who from this time became amalgamated with them), and established a mighty empire, which included, besides Persia, as far as the Oxus and Indus, Asia Minor, Syria, Palestine, and Mesopotamia. His son, Cambyses, a most ferocious and bloodthirsty tyrant (529–522), subdued Tyre, Cyprus, and Egypt. After the brief rule of the usurper Smerdis (522–521), Darius I. (q.v., surnamed Hystaspes—the Gushtasp of the Persians—521–485) mounted the throne. He was a politic and energetic prince, and succeeded in firmly establishing his dynasty, and adding Thrace and Macedonia to his empire; but his two attempts to subdue Greece were completely foiled, the first by the Thracians, and the second by the Athenians at Marathon (490). His son, Xerxes I. (485–465), renewed the attempt to subdue the Greek states, and, though at first successful, was compelled by the defeats of Salamis and Platæa to limit himself to a defensive warfare, which exhausted the resources of his kingdom. His son, Artaxerxes I. (465–425), surnamed Longimanus (the Bahman of the Persians, better known as Ardeshir Dirazdust), was a valiant prince, but he was unable to stay the decadence of Persia, which had now commenced. He, however, crushed a formidable rebellion in Egypt, though his wars with the Greeks and Ionians were unsuccessful. The empire now became a prey to intestine dissensions, which continued during the reigns of his successors, Xerxes II., Sogdianus, Darius II., Artaxerxes II., and Artaxerxes III. Darius III. Codomannus (336–329), the last of the dynasty, was compelled to yield his throne to Alexander the Great (known as Iskander or Secunder by the Persians), who reconquered all the former provinces of Persia, and founded a vast empire, which at his death, in 324, was divided into four parts, Persia along with Syria falling to the share of the Selencidæ, and its old dependency, Egypt, to the Ptolemies.

The Selencidæ soon lost Bactria (now Balkh), which became independent under a series of Greek sovereigns; and about 246 Parthia (q.v.; now Northern Khorassan) also rebelled under Arsaces I., who founded the dynasty of the Arsacidæ, under whom the greater part of Persia was wrested from the Greeks, and maintained against both the Greeks and Romans. The Greek empire of Bactria, which is said to have included a great part of India, was overthrown by an influx of nomad tribes from Turkestan (160–140); and these invaders having been driven out by the Parthians, Bactria was added to their empire (138). But the dynasty of the Arsacidæ, which maintained itself for four hundred and fifty years, was brought to an end by a Persian named Ardashir Babegan, who managed to gain possession of Fars, Kerman, and nearly the whole of Irak, before Arduan, the Parthian king, took the field against him. At last a great battle was fought (218 A.D.) on the plain of Hormuz, in which the Persians were completely victorious. Babegan was now hailed as Ardashir (Artaxerxes), king of Persia, and 'Shahan Shah,' or king of kings, his dynasty being named Sassanidæ from his grandfather Sassan. The Sassanian kings raised Persia to a height of power and prosperity such as it never before attained, and more than once imperilled the existence of the eastern empire. The most notable kings of the dynasty were Shahpur I. or Sapor (240–273), who routed the Romans, and took the Emperor Valerian captive at Edessa; his grandson, Shahpur II., who also maintained an equal conflict with the Romans; and Chosroes I. and II. (q.v.), the latter of whom was ultimately crushed by Heraclius (q.v.) in 628.

The last Sassanian king, Yezdigerd (Yazdajird), was driven from the throne, after a great battle at Nahavend (639), by the Arabs, who now began to extend their dominion in all directions; and from this period may be dated the gradual

change of character in the native Persian race, for they have been from this time constantly subject to the domination of alien races. During the reigns of Omar (the first of the Arab rulers of Persia), Othman, Ali, and the Ommiades (634–750) Persia was regarded as an outlying province of the califate, and was ruled by deputy governors; but after the accession of the Abbaside dynasty (750) Bagdad became the capital, and Khorassan the favourite province of the early and more energetic rulers of this race, and Persia consequently came to be considered as the centre and nucleus of the califate. But the rule of the califs soon became merely nominal, and ambitious governors, or other aspiring individuals, established independent principalities in various parts of the country. Many of these dynasties were transitory, others lasted for centuries, and created extensive and powerful empires. The chief were the Taherites (820–872), a Turkish dynasty in Khorassan; the Soffarides (Persian, 869–903), in Seistan, Fars, Irak, and Mazanderan; the Samani, in Transoxiana, Khorassan, and Seistan; the Dilemi (Persian, 933–1056), in western Persia; and the Ghaznevids (q.v.), in eastern Persia. These dynasties supplanted each other, and were finally rooted out by the Seljuks (q.v.), whose dominion extended from the Hellespont to Afghanistan. A branch of this dynasty, which ruled in Khaurezm (now Khiva), gradually acquired the greater part of Persia, driving out the Ghaznevids and their successors, the Ghurids; but they, along with the numerous petty dynasties which had established themselves in the south-western provinces, were all swept away by the Mongols under Genghis Khan (q.v.) and his grandson, Hulagu Khan, the latter of whom founded a new dynasty, the Perso-Mongol (1253–1335). This race, becoming effeminate, was supplanted by the Eylkhanians in 1335; but an irruption of the Tartars of Turkestan under Timúr (q.v.) again freed Persia from the petty dynasties which misruled it. After the death of Timúr's son and successor, Shah Rokh, the Turkomans took possession of the western part of the country, which, however, they rather preyed upon than governed; while the eastern portion was divided and subdivided among Timúr's descendants, till, at the close of the 15th century, they were swept away by the Uzbegs (q.v.), who joined eastern Persia to their newly-founded khanate of Khiva.

A new dynasty (Sufi) now arose (1500) in western Persia, the first prince of which (Ismail, the descendant of a long line of devotees and saints), having become the leader of a number of Turkish tribes who were attached by strong ties of gratitude to his family, overthrew the power of the Turkomans, and seized Azerbijan, which was the seat of their power. Ismail rapidly subdued the western provinces, and in 1511 took Khorassan and Balkh from the Uzbegs; but in 1514 he had to encounter a much more formidable enemy—to wit, the mighty Selim, the Sultan of Turkey, whose zeal for conquest was further inflamed by religious animosity against the Shiites (q.v.). The Persians were totally defeated in a battle on the frontiers; but Selim reaped no benefit from his victory, and after his retreat Ismail attacked and subdued Georgia. The Persians dwell with rapture on the character of this monarch, whom they deem to be not only the restorer of Persia, but the establisher of the faith in which they glory as the national religion—viz. the *Shiah*, as distinguished from the *Sunni* sect of Mohammedanism. His son Tamasp (1523–76), a prudent and spirited ruler, repeatedly drove out the predatory Uzbegs from Khorassan, sustained without loss a war with the Turks, and assisted Homayun, the son of Baber, to regain the throne of Delhi.

After a considerable period of internal revolution, during which the Turks and Uzbegs attacked the empire without hindrance, Shah Abbas I. the Great (1585–1628) ascended the throne, restored internal tranquillity, and repelled the invasions of the Uzbegs and Turks. In 1605 he inflicted on the Turks such a terrible defeat as kept them quiet during the rest of his reign, and enabled him to recover the whole of Kurdistan, Mosul, and Diarbekir, which had for a long time been separated from Persia; and in the east Kandahar was taken from the Great Mogul. Abbas' government was strict, but just and equitable; roads, bridges, caravanserais, and other conveniences for trade were constructed at immense expense, and the improvement and ornamentation of the towns were not neglected. His tolerance was remarkable, as he encouraged the Armenian Christians to settle in the country. Of his successors, Shah Sufi, Shah Abbas II., and Shah Soliman, the two former were sensible and judicious rulers, and advanced the prosperity of their subjects. During the reign of Sultan Hussein, a weak and bigoted fool, priests and slaves were elevated to the most important and responsible offices of the empire, and all who rejected the tenets of the Shiites were persecuted. The consequence was a general discontent, of which the Afghans took advantage to declare their independence and seize Kandahar (1709). Their able leader, Meer Vais, died in 1715; but his successors were worthy of him, and one of them, Mahmud, invaded Persia (1722), defeated Hussein's armies, and besieged the king in Ispahan till the inhabitants were reduced to the extremity of distress. Hussein then abdicated the throne in favour of his conqueror, who, on his accession, immediately devoted his energies to alleviate the distresses and gain the confidence of his new subjects. Becoming insane, he was deposed in 1725 by his brother Ashraf; but the atrocious tyranny of the latter was speedily put an end to by the celebrated Nadir Shah (q.v.), who first raised Tamasp (1729), of the Suffavean race, to the throne, then deposed him and made his young son the nominal sovereign, and finally, on the latter's early death, himself seized the sceptre (1736). But on his death (1747) anarchy again returned; the country was horribly devastated by the rival claimants for the throne; Afghanistan and Beluchistan finally separated from Persia, and the country was split up into a number of small independent states till 1755, when a Kurd, named Kerim Khan, re-established peace and unity in western Persia, and by his wisdom, justice, and warlike talents acquired the esteem of his subjects and the respect of neighbouring states. After the usual contests for the succession, accompanied with the usual barbarities and devastations, Kerim was succeeded in 1784 by Ali-Murad, Jaafar, and Lutf-Ali, during whose reigns Mazanderan became independent under Aga-Mohammed, a Turkoman eunuch of the Kajar race, who repeatedly defeated the royal armies, and ended by depriving Lutf-Ali of his crown (1795).

The great eunuch-king, the first of the present dynasty, on his accession announced his intention of restoring the kingdom as it had been established by Kerim Khan, and accordingly invaded Khorassan and Georgia. The Georgians besought the aid of Russia; but the Persian monarch, with terrible promptitude, poured his army like a torrent into the country, and devastated it with fire and sword. His conquest was, however, hardly completed when he was assassinated (1797). His nephew, Fath-Ali (1797–1834), after numerous conflicts, fully established his authority, and completely subdued the rebellious tribes in Khorassan. But the great commotions in

western Europe produced for him bitter fruits. He was dragged into a war with Russia soon after his accession, and by a treaty concluded in 1797 surrendered to that power Derbend and several districts on the Kur. In 1802 Georgia was declared to be a Russian province. War with Russia was recommenced by Persia at the instigation of France; but, after two years of conflicts disastrous to the Persians, the treaty of Gulistan (1813) gave to Russia all the Persian possessions to the north of Armenia, and the right of navigation in the Caspian Sea. In 1826 a third war, equally unfortunate for Persia, was commenced with the same power, and cost Persia the remainder of its possessions in Armenia, with Erivan, and a sum of 18,000,000 rubles for the expenses of the war. The severity exercised in procuring this sum by taxation so exasperated the people that they rose in insurrection (1829), and murdered the Russian ambassador, his wife, and almost all who were connected with the Russian legation. The most humiliating concessions to Russia, and the punishment by mutilation of 1500 of the rioters, alone averted war. The death of the crown-prince, Abbas Mirza, in 1833, seemed to give the final blow to the declining fortunes of Persia, for he was the only man who seriously attempted to raise his country from the state of abasement into which it had fallen. By the assistance of Russia and Britain Mohammed Shah (1834–48), the son of Abbas Mirza, obtained the crown. Mohammed resolved to demand reacknowledgment of sovereignty from his alleged vassals in parts of Afghanistan, Beluchistan, and Khiva, but an attempt he made to reannex Herat, 'the key to India,' was resisted by England. The war was terminated in 1838 by the landing of a small sepoy force on the shores of the Persian Gulf.

Nasr-ed-Din succeeded to the throne on his father's death in 1848. The new government announced energetic reforms, but at first failed as completely as those which had preceded it in carrying them out. Following his father's example, the new Shah resolved to reassert his claims in Afghanistan and Beluchistan. The ruler of Herat having recognised the claims of Persia, the English government remonstrated with the Shah, and he was compelled to sign an engagement (1853), by which he became bound not to interfere further with the internal affairs of Herat. In 1856, however, on the pretext that Dost Mohammed, the Ameer of Kabul, was about to invade Herat, the Persians again took the city. Thereupon a British army was landed on the coast of the gulf, and, under Generals Outram and Havelock, repeatedly defeated the Persians, and compelled them to restore Herat (July 1857). Since that time the Persians have not interfered with the 'key to India,' but they have been engaged in a long series of disputes with regard to their frontier north and south of it. After the war of 1857 their encroachments became systematic. In 1868 they occupied Seistan, a province claimed by the Afghans, and extended their jurisdiction over part of Beluchistan; but at length they agreed with the Ameer of Afghanistan and the Khan of Kelat to refer the questions in dispute to an English commissioner, General Sir Frederick Goldsmid, who in 1872 fixed the Persian frontier substantially as it now is—a large triangular tract to the east of Lake Zirreh, watered by the Helmund, being annexed to Persia. By the treaty of Berlin in 1878 the town and territory of Khotour, on the Turco-Persian frontier, was ceded to Persia by Turkey. The north-eastern frontier was settled by a treaty between Russia and Persia in 1881. The great extension of Russian territory and Russian power on the north-east, while overshadowing Persia to some extent, have had the effect of sheltering the adjoining regions of Persia from the terrible inroads of the Tekke and other Turkomans, now under Russian authority. English officers, including Sir John Bateman-Champain, Sir R. Murdoch Smith, Sir Oliver St John, and Captain Pierson, did much to explore and indirectly to improve the local government of Persia in connection with the establishment, in 1864, of the Indo-European telegraph line. Now there are 4500 miles of telegraph line in Persia, partly worked by Englishmen, partly by the Persian government. In 1896 Nasr-ed-Din was assassinated, and his second son, Muzaffer-ed-Din, peacefully succeeded to the throne.

Watson (1866), and Clements Markham (1874); Rawlinson's *The Seventh Great Oriental Monarchy* (1876); and German works by Justi (1879), Nöldeke (1887), and Gutschmid (1888).

PERSIAN ARCHITECTURE.—The architecture of Persia and that of Assyria closely resemble one another, and, owing to the mode and the materials in which they were constructed, their remains serve to illustrate and complete each other's history. In Assyria, where no solid building-materials exist, the walls are composed of masses of sun-dried brickwork, lined on the inside, to a certain height from the floor, with large sculptured slabs of alabaster. These have been preserved to us by the falling in of the heavy earthen roofs, with which, as the later Persian buildings explain to us, the Assyrian palaces were covered. The explorations of Layard and Botta have made these sculptures familiar to us. The Assyrian remains are all of palace-temples, buildings somewhat resembling the Egyptian temples (which were also palaces); and many of the sculptures represent the exploits of the king in war and in peace. The palaces are always raised on lofty artificial mounds, and approached by magnificent flights of steps.

The buildings of Assyria extend over a very long period, the oldest at Nimroud being from 1300 to 800 B.C., and the more recent at Khorsabad and Koyunjik from 800 to 600 B.C. To these succeeded Babylon in the reign of Nebuchadnezzar, and the Birs Nimroud; but these are mere masses of decomposed brickwork, without any sculptures of harder material (see ASSYRIA).

After Babylon came Pasargadæ, where the splendid palaces of Cyrus and Cambyses still exist in ruins, and Persepolis, the capital of Darius and Xerxes (560–523 B.C.); and some remains are still to be found at Susa, Ecbatana, and Teheran. At Persepolis we find the very parts preserved which at Nimroud and Khorsabad are wanting; for here there is abundance of stone, and the pillars, walls, doorways, &c. (which in the early examples were no doubt of wood, and have decayed), being of stone, are still preserved. This enabled Fergusson to 'restore' these buildings; the subject has been further studied and illustrated with great care by M. Dieulafoy in *L'Art Antique de la Perse* (1884).

The halls at Persepolis were square in plan, having an equal number of pillars in each direction for the support of the roof, which was flat. In the

centre a portion was left open for the admission of light, and sheltered by another roof raised upon pillars. The remains of the seventy-two columns with which it was adorned are still extant (fig. 1). The hall had thirty-six columns, six on each side, and on three sides had an external portico, each with two rows of six columns. These columns had

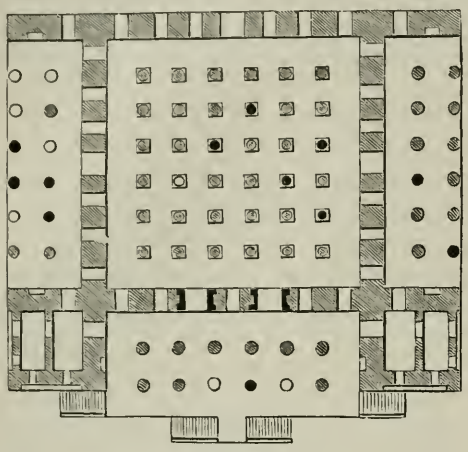


Fig. 1.—Plan of Great Hall of Xerxes at Persepolis.

capitals, composed of bulls' heads and shoulders (fig. 2), between which the beams of the roof rested; while others were ornamented with scrolls like the Ionic order (fig. 3). The bases also are suggestive of the origin of that Greek style. This hall was 350 feet by 300, and covered more ground than any similar buildings of antiquity, or any mediæval cathedral except that of Milan. The palaces of Persepolis stand on lofty platforms, built with walls of cyclopean masonry, and approached by magnificent flights of stairs, adorned, like the palaces, with

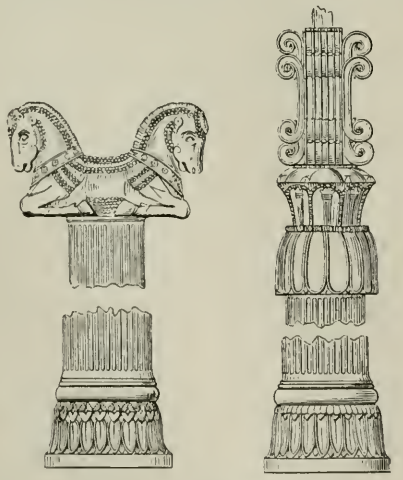

Fig. 2. Fig. 3.
Details of Persian Architecture.

sculptures somewhat similar to those of Assyria. The interiors were ornamented with paintings. The use of the arch was known in Assyria, as has been shown by the subterranean arched conduits discovered by Layard, and the gates of Khorsabad discovered by M. Place. The arches of the latter spring from the backs of sculptured bulls, and are beautifully ornamented with enamelled bricks. In 1886 some extremely interesting discoveries were made at Susa (Shushan) in south-western Persia by M. and Madame Dieulafoy, who unearthed and sent to the Louvre a splendid frieze in coloured enamelled bricks with life-sized figures of warriors from the palace of Darius I., and another similar frieze with lions from the palace of Artaxerxes. A fac-simile reproduction of the warrior frieze is in the Edinburgh Museum of Science and Art.

Modern Persian architecture is separated by a wide historic gap from that of ancient Persia, and, all posterior to the Moslem conquest, belongs to the type known as Saracenic or Arabian. But it seems that the old art of Persia has a more direct influence on that of modern Persia than has been sometimes admitted; and even the Egyptian type of Saracenic art (see ARABIAN ARCHITECTURE) may have been moulded by Persian as well as by Byzantine artists, working for the Moslem conquerors. In Persia itself there seems no doubt that architecture of Mohammedan Persia, which in its palmiest days rivalled in splendour that of Egypt, Bagdad vying with Cairo, is in many

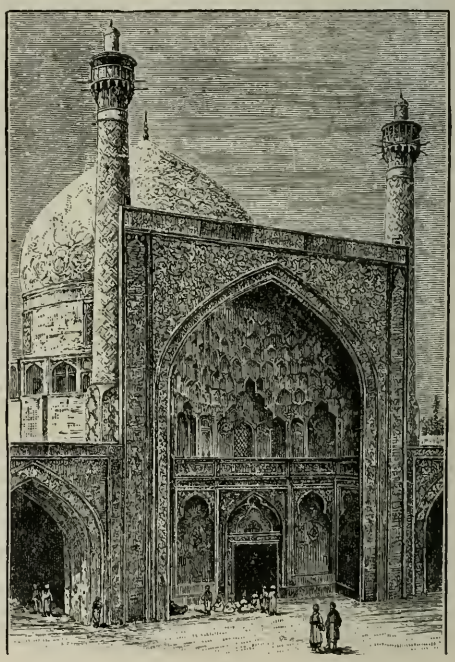

Fig. 4.—Gateway of Masjid Shah, Ispahan.

respects a reproduction of the ancient palaces of Nineveh and Babylon. In the mosques thick walls of imperfectly burnt bricks are covered with brilliantly coloured decorations of glazed and painted tiles and bricks. Fig. 4 is a view of the gateway of the Masjid Shah, or Great Mosque of Ispahan, dating from the reign of Shah Abbas the Great (1585–1628 A.D.).

PERSIAN LANGUAGE AND LITERATURE.—The ancient and modern idioms of Persia, which are in general designated as Iranian or West Aryan, belong to the great class of the Indo-European languages; but the term Persian itself applies more particularly to the language as it is now spoken, with a few exceptions, throughout Persia, and in a few other places formerly under Persian dominion, like Bokhara, &c. The more important and better known of the ancient idioms are (1) the *Zend* (the East Iranian or Bactrian language, in two dialects—the 'Gátha idiom' and the

'ancient' or 'classical Zend'), which died out in the 3d century B.C.—one of the most highly developed idioms, rich in inflections, in the verbs as well as in the nouns, and in the former almost completely agreeing with Vedic Sanskrit; yet such as we find it in the small remains which have survived it is no longer in the full vigour of life, but almost decaying, and grammatically somewhat neglected. Geographically, this idiom may be placed in northern Persia. Its alphabet is of Semitic origin, and the writing goes from right to left (see ZEND, ZEND-AVESTA). (2) *Ancient Persian*, the chief remnants of which are found in the cuneiform inscriptions of the time of the Achæmenides, discovered in the ruins of Persepolis, on the rock of Behistun, and some other places of Persia (see CUNEIFORM). Some relics, chiefly consisting of proper names for gods and men, and terms for vessels and garments, have survived in the writings of the classical period, and in the Bible, chiefly in Daniel. This idiom is much nearer to Zend and Sanskrit than to modern Persian. (3) *Pehlevi* (West Iranian, Median, and Persian), in use during the period of the Sassanides (3d to 7th century A.D.), an idiom largely mixed with Semitic words, and poorer in inflections and terminations than Zend. Its remnants consist of a certain number of books relating to the Zoroastrian religion, of coins and inscriptions; and the language is not quite the same in all cases—according to the larger or smaller infusion of foreign words. The non-Iranian element is known as Huzvaresh, and is simply Chaldee; while the Iranian element is but little different from modern Persian. There are three distinct idioms to be distinguished in Pehlevi, and the writing varies accordingly, yet it is not certain whether the difference arises from their belonging to different districts or periods. When, however, Pehlevi ceased to be a living language, and the restoration of the pure Iranian had begun, people, not daring to change the writings (chiefly of a sacred nature, as having descended to them from the Sassanian times), began to substitute in reading the Persian equivalents for the Huzvaresh words. At last a new form of commentaries to the sacred writings sprang up, in which more distinct and clear Zend characters were used, where each sign had but one phonetic value, and where all the foreign Huzvaresh words were replaced by pure Persian ones; and this new form was called (4) *Pázend*. The transition from the ancient to the modern Persian is formed by the *Parsee*, or, as the Arabs and the modern Persians themselves call it, *Farsi*, in use from 700 to 1100 A.D., once the language purely of the south-western provinces, and distinguished chiefly by a peculiarity of style, rigid exclusion of Semitic words, and certain now obsolete forms and words retained in liturgical formulas. It is the Persian once written by the Parsees or fire-worshippers, and is in other respects very similar to the present or *modern Persian* (which also is invariably called *Farsi* by the modern Persians), the language of Jami, Nizami, and Háfiz—from 1100 to the present time—with its numerous dialects. The purest dialect is said to be that spoken in Shiraz and Ispahan and their neighbourhood. In general, the language is pronounced by universal consent to be the richest and most elegant of those spoken in modern Asia. It is the most sonorous and muscular, while at the same time it is the most elegant and most flexible of idioms; and it is not to be wondered at that in Moslem and Hindu realms it should have become the language of the court and of the educated world in general, as French used to be in Europe. Its chief characteristic, however, is the enormous intermixture of Arabic words, which, indeed, make up almost half its vocabulary. Respecting its analytical and grammatical structure, it exhibits traces only of that of the ancient dialects of Zend and Achæmenian, of which it is a direct descendant. The elaborate system of forms and inflections characteristic of those dialects has been utterly abandoned for combinations of auxiliary words, which impart fullness and an incredible ease to speech and composition. The grammar of the Persian language has been called 'regular;' but the fact is that there is hardly any grammar worth mentioning. Thus, there is no gender distinguished in declension; the plural is always formed in the same manner, the only distinction consisting in animate beings receiving the affix *án*, while the inanimate are terminated in *há*. Imported Arabic nouns, however, invariably take their Arabic plural. Not even the pronouns have a gender of their own; the distinction between masculine and feminine must be expressed by a special word, denoting male or female. There is no article, either definite or indefinite. The flexion of the verb is equally simple. As to syntax, there is none, or, at all events, none which would not come almost instinctively to any student acquainted with the general laws of speech and composition. The time of its greatest brilliancy may be designated as that in which Firdausí wrote, when Arabic words had not swamped it to the vast degree in which they have since done, and were still, as far as they had crept in, amenable to whatever rules the Persian grammar imposed upon the words of its own language.

In the history of the Persian writing three epochs are to be distinguished. First, we have the Cuneiform (q.v.), by the side of which there seems, however, to have been in use a kind of Semitic alphabet for common purposes. This, in the second period, appears to have split into several alphabets, all related to each other, and pointing to a common Syriac origin (such as the different kinds of Pehlevi characters and the Zend alphabet) cleverly adapted to the use of a non-Semitic language. In the third period we find the Arabic alphabet enlarged for Persian use by an addition of diacritical points and signs for such sounds as are not to be found in Arabic (*p*, *ch*, *zh*, *g*). The writing is but slightly different from the usual Arabic Neskhi.

Of the literature of the Persians before the Mohammedan conquest we shall not speak here, but refer to the article ZEND. The literary period now under consideration is distinguishable by the above-mentioned infusion of Arabic words into the Persian language, imported together with the Koran and its teachings. The writers are one and all Mohammedans. With the fanaticism peculiar to conquering religions, all the representatives of old Persian literature and science, men and matter, were ruthlessly persecuted by Omar's general, Saad Ibn Abi Wakkas. The consequence was that for the first two or three centuries after the conquest all was silence. The scholars and priests who would not bow to Allah and his Prophet took with them what had not been destroyed of the written monuments of their ancient culture, while those that remained at home were forced to abandon their wonted studies. Yet, by slow degrees, as is invariably the case under such circumstances, the conquered race transformed the culture of the conquerors to such a degree that native influence soon became paramount in Persia, even in the matter of theology. It is readily granted by later Mohammedan writers that it was out of the body of the Persians exclusively that sprang the foremost, if not all, the greatest scholars and authors on religious as well as grammatical subjects, historians and poets, philosophers and men of science; and the only concession they made consisted in their use of the newly-imported Arabic

tongue. A further step was taken when the Persians, under upstart native dynasties, returned also to the ancient language of their fathers during the first centuries of Mohammedanism. The revived national feeling, which must have been stirring for a long time previously among the masses, then suddenly burst forth in prose and in verse, from the lips of a thousand singers and writers. The literary life of Persia, the commencement of which is thus to be placed in the 9th century A.D., continued to flourish with unabated healthy vigour for five centuries, and produced a host of writers in every branch of science and belles-lettres, of whom we can only here give the most rapid of surveys, referring for the most important names to special articles.

About 952 Abul Hasan Rudegi, the Blind, rose by the king's favour to such an eminence that he had two hundred slaves to wait upon him; but little has remained of his 1,300,000 distichs, and of his metrical translation of Bidpai's Fables. About 1000 we hear of Kabus, the Dilemite prince, as the author of *The Perfection of Rhetoric*, and poems. In the time of the Ghaznevids, chiefly under Mahmud, who surrounded himself with no less than four hundred court-poets, we find those stars of Persian song, Ansari (1039), author of *Wamik and Asra*; Ferruchi, who, besides his own poems, wrote the first work on the laws of the Persian metrical art; Esedi, from Tus; and, above all, Firdausi (q.v.), the author of the *Shah-Nameh*. Under the Atabek dynasty was the panegyrist Auhad-ed-Din Anwari, who, with his praise, well knew how to handle satire. Nizami (about 1200) is founder of the romantic epos. Conspicuous in Persia is the mystic (Sufistic) poetry, which, under Anacreontic allegories, in glowing songs of wine and love, represented the mystery of divine love and of the union of the soul with God (see SUFISM). In this province we find the famous Omar Khayyam (q.v.; died 1123), and Farid-ed-Din Attar (born 1216), the renowned author of *Pend-Nameh* ('Book of Counsel'), a work containing the biographies of saints up to his own time; such is the depth and hidden meaning of his mystic poems that for centuries after him the whole Moslem world has busied itself with commentaries on the meaning of his sacred poetry. He died about 1330, more than a hundred years old, as a martyr. Greater still in this field is Jelal-ed-Din Rumi (died 1273), whose poem on *Contemplative Life* has made him the oracle of oriental mysticism up to this day; he wrote also a great number of lyrical poems. The 13th century cannot better be closed than with Sádi (q.v.), the first and unrivalled Persian didactic poet. But far above all shines Hátiz (q.v.), who sang of wine and love, and nightingales and flowers. After him the full glory of Persian poetry begins to wane. Among those that came after him Jami (1419–92) stands highest, a poet of most varied genius, second only in every one of the manifold branches to its chief master—in lyric and in didactic to Sádi, in romance to Nizami, in mysticism to Jelal-ed-Din; but most brilliant as a romantic poet. Of prose works we have by him a history of the Sufis, and an exceedingly valuable collection of epistolary models. The dramatic poetry of the Persians is not without merit, but is of small extent.

The numerous tales, stories, novels, anecdotes, anthologies, and all the miscellaneous entertaining literature in which Persia abounds form a fit transition from poetry to prose. Able rivals of the great Arabic historiographers sprang up at an early period. For the mythical times Firdausi's gigantic epos remains the only source. Reshid-ed-Din, the vizier of Ghazan (born 1247; executed in 1320), wrote a summary of the history of all Mohammedan countries and times, containing besides a complete history of sects. His contemporary Wassaf is the model of the grand rhetorical style. His most successful imitator in the 15th century is Sherif-ed-Din, who wrote the history of Tamerlane. Up to that period pomposity of diction was considered the principal beauty, if not the chief merit, of a classical Persian history. From the 15th century downwards a healthy reaction set in, and simplicity and a striving after the real representation of facts became the predominant fashion. Foremost among the modern historians is Mirkhond, whose Universal History comprises the period from creation to the reign of Sultan Hasan Beikara. His son Khondemir also wrote history. Among Indian historians who wrote in Persian we have Mohammed Kasim Ferishtah (1640), who wrote the ancient history of India up to the European conquest, Mohammed Hashim, Abul Fadel Mobarrek, and others. The *Measiri Sultaniye*, which contains the history of the present dynasty of Persia, and was published at Teheran in 1825, was translated by Bridges (Lond. 1833).

Biographies, legends, histories of martyrs, and the like are legion. Most of the biographies of the Prophet, however, are taken from the Arabic. Works on geography—generally treated together with history—are those of Mestafi, Ahmin Ahmed Rasi, Berdshendi, &c. In theology little beyond translations of the Koran, commentaries, and some portions of the Traditions has been produced. Jurisprudence has likewise to show little that is original, and not mere translation, partial commentary, or adaptation in Persian. The *Hedad-shah*, the *Inadshah*, the *Futawa Alemgiri* are the most important legal works. Much has been written on medicine, surgery, pharmacy, and physical sciences by Persians, but nearly all their chief works are in Arabic. Mathematics, astronomy, and philosophy have not been neglected; rhetoric, works on letter-writing, and on metrical and poetical arts are numerous. Grammar and lexicography found their principal cultivators in India. Translations from Greek, Indian, Arabic, Turkish, and other languages into Persian exist in abundance.

There is no good history of Persian literature; but there is much information in the great catalogues of Stewart (1809), Ouseley (1831), Morley (1854), Sprenger (Calcutta, 1854), Rieu (Lond. 1879), and others. See the articles in this work on FIRDAUSÍ, HÁFIZ, OMAR KHAYYÁM, SUFISM, &c. Dictionaries, besides the native ones, are those of Johnson and Richardson, Vullers (1867), Palmer (1876–84), Steingass (1884–92), Wollaston (1889).

Persian Gulf, an arm of the Indian Ocean which penetrates between Arabia and Persia to the extent of 650 English miles in a general north-westerly direction. Its breadth varies from 55 miles at the mouth to 250 miles, and the area is estimated at 77,450 sq. m., not including the islands, which are scattered over the western half, or lie close inshore along the eastern side. The chief of these islands are Ormuz, at the mouth; Kishm, 810 sq. m. in extent; and the Bahrein Islands. The Great Pearl Bank stretches along the western side from Ras Hassan to nearly half-way up the gulf. The coast is mostly formed of calcareous rocks. On the Arabian side it is low and sandy, occasionally broken by mountains and cliffs; while on the Persian side it is higher and abrupt, with deep water close inshore, owing to the mountain-ranges of Fars and Laristan running close to the water's edge. The islands are partly of limestone and partly of ironstone, and are generally destitute of springs, barren, desolate, and presenting numerous traces of volcanic eruptions. Except the Shat-el-Arab (see EUPHRATES), the Persian Gulf receives only insignificant streams. Its eastern side presents

abundance of good anchorage, either in the numerous bays or in the lee of islands. The greater portion of its southern shores now belongs to the Imam of Muscat, while the whole of the northern shore belongs to Persia. The order of the periodic currents in this gulf is precisely the reverse of that of the Red Sea (q.v.) currents, as they ascend from May to October, and descend from October to May. The greatest depth does not exceed 50 fathoms; and Dr John Murray calculates its total cubic contents at 2200 cubic miles of water. Oriental geographers give to this gulf the name of the 'Green Sea,' from a remarkable strip of water, of a green colour, lying along the Arabian coast.

The submarine telegraph cables belonging to the government of India, and forming part of the system of the Indo-European Telegraph, pass through the whole length of the Persian Gulf, from Fao at the mouth of the Shat-el-Arab, where they connect with the Turkish lines, to Bushire, where they connect with the Persian, and thence to Jask, Gwadur, and Kurrachee, where they connect with the general telegraph system of India. Among the ports are Bender Abbas (q.v.), Bushire (q.v.), and Lingah (pop. 8000).

Persian Powder. See INSECT-POWDER.

Persigny, JEAN GILBERT VICTOR FIALIN, DUC DE, an adherent of Napoleon III., was born at Saint-Germain-l'Espinasse (dept. Loire), 11th January 1808, entered the cavalry school at Saumur in 1826, and the 4th Hussars in 1828; but he was expelled from the army for insubordination in 1831. Then, having been introduced to Louis Napoleon, he secured his favour, and commenced a career of Bonapartist propagandism throughout France and Germany. He had the chief hand in the affair of Strasburg (1836) and in the descent on Boulogne (1840), but was captured there, and condemned to twenty years' imprisonment. On the breaking out of the revolution in 1848 Persigny was one of the men who secured the election of Napoleon as President of the Republic; he also took a prominent part in the *coup d'état* of December 1851. In January 1852 he succeeded De Morny as minister of the Interior; from 1855 to 1860 (except for one year) he was ambassador at the English court; then he resumed the office of minister of the Interior until June 1863. In September of the same year he was created duke. Thereafter he sat in the senate until the fall of the empire, when he escaped to England. He died at Nice on 12th January 1872.

Persimmon. See DATE PLUM.

Persius (AULUS PERSIUS FLACCUS), third in the line of Roman satirists, being later than Lucilius and Horace and earlier than Juvenal, was in some respects the ablest, certainly the most dramatic, of the four. Born of a distinguished equestrian family, 4th December 34 A.D., at Volaterræ in Etruria, he lost his father when six years old, was educated till twelve in his native town, and thereafter in Rome under the grammarian Remmius Palæmon and the rhetorician Verginius Flavius. In early manhood he came under the ennobling influence of the Stoic philosopher Cornutus, who imbued him with the tenets of his school and gave his mind and character an impress which ever deepened and strengthened. But he died before completing his twenty-eighth year (62 A.D.). The admiration and affection entertained by the master for his pupil was shared by the friends of the latter—Lucan, Cæsius Bassus, the lyric poet, and other contemporaries of light and leading, among whom, however, Seneca had little attraction for the young author. The noble and virtuous Pætus Thrasea accompanied him on several tours through Italy, finding a kindred soul in the modest, prepossessing youth, whose integrity and piety were conspicuous in his worldly as in his family relations. The austere discipline of Cornutus affected the style of Persius, who in consequence wrote fastidiously and sparingly, leaving at his death six brief satires, the whole not exceeding 650 hexameter lines. These, slightly corrected by Cornutus and edited by Cæsius Bassus, enjoyed, even through the early mediæval darkness till the Renaissance and down to our own day, the highest esteem, fathers of the church like Augustine and Jerome, humanists like Buchanan and Casaubon, anticipating later schools of literature in evolving and interpreting the poet's pregnant, if sometimes obscure, ridicule of the rapidly degenerating life of 1st-century paganism. The best satire is, on the whole, the first, on the prevailing false taste in poetry. 'Probably no writer ever borrowed so much and yet left on the mind so decided an impression of originality,' says Conington, who further indicates the striking resemblance between the genius of Persius and that of Carlyle. He has had many editors, of whom the most helpful have been Casaubon (1605), Otto Jahn (1843–68), and Conington, whose edition, revised by Nettleship (Oxford, 1878), gives text, prose translation, and notes embodying the best results of previous criticism. He has had a host of translators in the chief modern languages—that of the Italian Sacchi of Faenza surpassing all others, not excepting the English versions by Dryden and Gifford.

Person (Lat. *persona*, 'a mask') came to be applied to the person wearing the mask, and thus to mean a personage, an individual, a numerically distinct being. In theology there is a special use of the word for the three Persons of the Trinity (q.v.). The name *Persona*, Person, was first applied to the Trinity by the Latins; the corresponding Greek word, *Prosōpon*, being of later use. The earlier Greek Fathers used the word *Hypostasis*, 'substance,' where the Latins used *Persona*, and considerable controversy for a time grew out of this diverse use; after the condemnation of the Sabellian heresy, and still more after the Council of Nicæa, all ambiguity of words being at an end, the controversy turned upon the substance of the doctrine, in the form of the Arian controversy. See ARIUS.

Personal Equation. See EQUATIONS.

Personal Exception, in the law of Scotland, the equivalent of the English *Estoppel* (q.v.); a ground of objection which applies to an individual and prevents him from doing something which, but for his conduct or situation, he might do.

Personality, as used in philosophy, signifies the distinctive attribute or attributes which distinguish a person from an animal or a thing. A thing we ordinarily consider to be unconscious, an animal to be conscious, a person to be self-conscious. That is to say, we suppose the animal to have intelligent experience of a kind, without being able to reflect upon that experience, and so to be conscious of itself as the unitary subject whose the experience is. The last is the essential mark of personality in the intellectual sphere. 'A person,' says Locke, 'stands for a thinking intelligent being, that has reason and reflection, and can consider itself as itself, the same thinking being in different times and places' (*Essay*, ii. 27). In the moral sphere personality means self-determination or reason-directed will, and may be said to be the foundation of moral responsibility. Hence the central position which it occupies in the ethics of Kant and Hegel. The consciously realised unity and identity of the individual thus constitutes what is most distinctive of personality as such. But under the name of *Double Personality* or *Double Consciousness* the records of medical science contain many

cases of mental disorder, in which the sense of personal identity is curiously interfered with. Cases are, of course, of constant occurrence in which the patient mentally affected conceives himself to be some one else (e.g. Napoleon or a Scripture characters). Others conceive that parts or properties of their frame belong to another person, or that they are inhabited and ruled by a spirit or entity acting in opposition to their will and interests. Others, again, are possessed by the idea that they are two persons at once, or rather that their body is the seat of two beings who are often in strife with one another, one being generally identified more strictly with the self, and the other being regarded as a hostile power and a *mauvais sujet* who prompts the better self to evil courses. The struggle between the two persons of this duality often takes bodily shape, and the patient maltreats his own body under the impression that he is castigating the vicious 'other one' who haunts him. This alienation or extrusion of part of the individual's experience from the inner circle of the personality may be due, it has been suggested, to a morbid alteration in the cœnæsthesis or organic sensations which represent in consciousness the state of the body as a whole. Any part of the body in which this common sensibility is wanting or disturbed is regarded by the patient as no longer a part of himself, and even as belonging to some hostile being. It even happens in extreme cases of such somatic insensibility that the individual doubts or denies his own existence, as in the case of a patient cited by Ribot, who declared that he had been dead two years, though (according to his own account) he still continued to exist in a mechanical fashion in which he was not consciously interested.

These manifestations, however, are not what is meant by double consciousness in the strict sense of the term. Double consciousness does not necessarily imply the presence of any insane delusion as to the patient's present existence and surroundings, but consists in the fact that a certain portion of his past life is temporarily withdrawn altogether from his conscious memory, to reappear, however, at a later period, when he will have as completely forgotten his present experiences and the whole section of his life connected with them. In the normal human being the memory is unitary, and consequently the life-experiences of the individual are felt and recalled as parts of one whole. In these morbid cases, on the contrary, the conscious life seems, as it were, to be cut into sections or lengths which are entirely dissevered, and retained, so to speak, in separate memories. These mutually exclusive sections are remembered by the individual intermittently in successive periods, generally separated from one another by a swoon, a fit, or some violent nervous crisis. Now, as it is our memory of past experiences that may be said to form the anchor of personal identity, it follows that in such cases we shall have, in greater or less completeness, the extraordinary phenomenon of two separate and independent trains of thought—consequently two separate personalities—in the same physical individual.

Perhaps the most clearly defined and complete instance on record is that of the young American woman reported by Macnish in his *Philosophy of Sleep*. She fell without forewarning into a profound sleep lasting several hours beyond the usual term. Before her sleep she was well informed and possessed an excellent memory. 'On waking she was discovered to have lost every trace of acquired knowledge. It was found necessary for her to learn everything again. She even acquired by new efforts the art of spelling, reading, writing, and calculating, and gradually became acquainted with the persons and objects around, like a being for the first time brought into the world. In these exercises she made considerable proficiency. But after a few months another fit of somnolency invaded her. On rousing from it she found herself restored to the state she was in before the first paroxysm, but was wholly ignorant of every event and circumstance that had befallen her afterward. She is as unconscious of her double character as two persons are of their respective natures. For example, in her old state she possesses all the original knowledge, in her new state only what she acquired since. In the old state she possesses fine powers of penmanship, while in the new she writes a poor, awkward hand, having not had time or means to become an expert.' A similar experience is observable in the case of somnambulists, who are totally ignorant, in the waking state, of their somnambulistic experience, but when again in the somnambulistic state recall what happened in the previous crisis. Lost objects have been recovered, and even crimes brought to light by taking advantage of this peculiarity. The same phenomenon is also said to have been observed in cases of intoxication, what is done in one fit of drunkenness being remembered in the next, but forgotten in the sober interval. Instances of double consciousness, however, are not always of the precise type mentioned by Macnish. Thus, in one of the most interesting of recent cases (that of Félida X., reported by Dr Azam), the woman was conscious during the second state of her whole life-experience, but during the first or original state knew nothing of anything that had happened in the second. The alternations began in this case in 1856, and continued for upwards of thirty years, and it is remarkable that the second state, which at first appeared only in short dream-like periods, has gradually supplanted the first state, which now recurs only at long intervals, and for a few hours. The second state is physically and mentally superior to the first, and the patient herself speaks of the first as *état bête*. A still more extraordinary case, reported from Paris, is that of Louis V., a young man of epileptic and hysterical temperament and criminal tendencies (born 1863), where the medical record signalises not two, but six states which are mutually exclusive, but which, taken together, embrace his whole past life. These and other cases are commented upon by Ribot in his *Diseases of Memory* and his *Maladies de la Personnalité*, and by Mr F. W. Myers in an article on 'Multiplex Personality' (*Nineteenth Century*, November 1886). The phenomena of double consciousness have also been aptly described as periodic amnesia. They evidently depend upon morbid action of the brain—it has been suggested, upon an abnormal severance and consequent independent action of the two hemispheres—but the physiological conditions are still full of obscurity. An ingenious literary use of the notion of double personality, on completely different planes of morality, is seen in Mr R. L. Stevenson's creation of Dr Jekyll and Mr Hyde.

Personalty, all the property which, when a man dies, goes to his executor or administrator, as distinguished from the realty, which goes to his heir-at-law. Personalty consists of money, furniture, stock in the funds; while realty consists of freehold land and rights connected with land. See INTESTACY, KIN (NEXT OF), REALTY. In Scots law, the corresponding phrase is Movables; see HERITABLE AND MOVABLE.

Perspective (Lat. *perspicio*, 'I look through') is the art of representing natural objects upon a plane surface in such a manner that the representation shall affect the eye in the same way as the

objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear perspective*, which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent *form* and *grouping* of objects; while *aerial perspective* confines itself to their *distinctness*, as modified by distance and light. The necessity of attending to the principles of perspective in all pictorial drawing is apparent when we consider, for instance, that a circle when seen obliquely appears to be not a circle but an ellipse, with its shortest diameter in line with the spectator, and its longest at right angles to this. A square, when looked at from a position opposite the middle of one of its sides, appears as a trapezoid, the sides which are perpendicular to the direction of vision appearing to be parallel, while the other two appear to converge to a point in front of the spectator, &c. For the same reason two rows of parallel pillars of equal height, seen from a point between and equidistant from each row, appear not only to converge at the further end, but to become gradually smaller and smaller. An excellent idea of a perspective plan can be easily obtained by interposing a vertical transparent plane (as of glass—a window, for instance) between the observer and the objects of his vision, and supposing that the objects he sees are not seen *through* the glass, but painted *on* it. A sketch made on a glass plane in this position by following with a pencil all the lines and shades of the objects seen through it, the eye being all the time kept quite steady, would form a picture in perfect perspective. In practice, however, it is found unfortunately that glass is not a suitable material for sketching on, and that the vertical position is not the most convenient; it is therefore preferable to make a careful study of the effects produced by change of position and distance on the appearance of objects in nature, and from the results of this to compile a body of rules, by the observance of which painters may be enabled to produce an effect true to nature. After the 'scope' (i.e. the number of objects to be introduced, and the distance at which they are to be viewed) of the picture has been determined, and before the design is commenced, it is necessary to draw upon the perspective plan three lines: (1) The *base line*, or *ground line*, limits the sketch towards the operator, and is the base line of the picture. (2) The *horizontal line* represents the ordinary position of the sensible horizon. The height of the horizontal line is about one-third of the height of the picture, when the sketcher is placed at or little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a mountainous landscape is figured, the horizontal line must be low. The horizontal line in nearly all cases is supposed to be level with the spectator's eye. (3) The *vertical line* is drawn from the supposed position of the sketcher, perpendicular to the *ground* and *horizontal* lines, meeting the latter in a point which is called the *point of sight*, or centre of the picture. The vertical line has no representative in nature, and is merely a mechanical adjunct to the construction of the picture, all vertical lines in nature being parallel to it in the picture. The point of sight, being the point directly opposite to the observer, is properly placed in the centre of the picture, for it is most natural that the view should lie symmetrically on each side of the principal visual line; but this is not by any means a universal rule, for we very frequently find it on the right or left side, but always, of course, on the horizontal line. All lines which in nature are perpendicular to the ground line, or to a vertical plane which is raised upon it as a base, meet in the point of sight, which is thus their *vanishing point* (see the line of the tops and bottoms of the pillars in fig. 1). The *points of distance* are two points in the horizontal line on each side of the point of sight, and in a 'direct' sketch are at a distance from it equal to the horizontal distance of the sketcher's eye from the ground line. The equality of distance of these points from the point of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the *vanishing points*, are inclined (in nature) at an angle of 45° to the base line; but in all cases the two points of distance are about twice as far apart as the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (fig. 1) from each other. For this purpose two points of distance are not necessary, as when the position of one pillar is found, that of the one opposite is at once obtained by drawing a line parallel to the base or ground line. We have seen that the point of sight is the vanishing point of all level lines which meet the ground line or a vertical plane on it at right angles, and that the points of distance (in a *direct* picture) are the vanishing points of all lines which cut the ground line at an angle of 45°; but there are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called for distinction's sake *accidental points*) are represented in fig. 2. If the accidental point is above the horizontal line, it is called the *accidental point aerial;* if below, the *accidental point terrestrial;* and a little consideration makes it evident that these points may or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above explanation we may deduce the two general principles: (1) that all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which case they remain parallel when transferred to the picture; and (2) that, since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and those to the right and left of the point of sight as if observed from the left and right, it follows that straight lines which in the picture are above the horizontal line lower themselves, those below raise

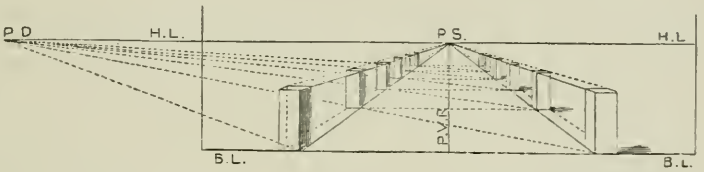

Fig. 1.

Illustrating the more important points and lines; PVR is the principal visual ray.

themselves to it, whilst those to the left, following the same law, direct themselves to the right, and *vice versâ*.

Aerial perspective consists in a modulation of the brightness and colours of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (i.e. distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it is frequently imitated by the mixing of a slight tint of blue with the colours to be applied; a yellow object thus assumes a greenish tint, a red one a violet tint, &c. The air when charged with vapour is represented by a diminution of the brightness of colours, and by the grayish tint imparted to them. But in this part of the subject rules are of little avail, for experience alone can guide the painter in faithfully copying the myriad aspects presented by nature.

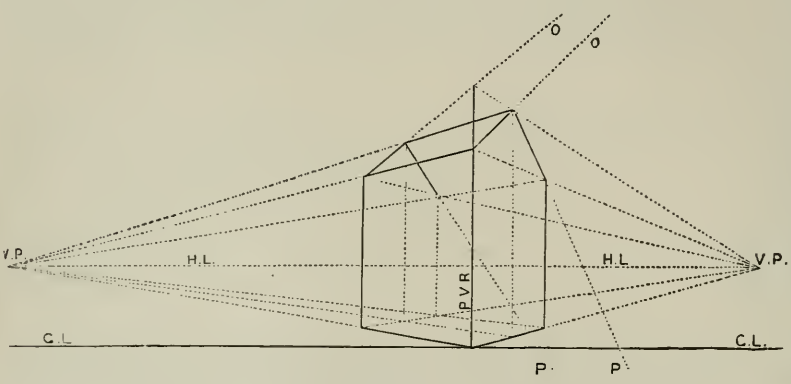

Fig. 2.
The lines O, O converge to the accidental point aerial, and P, P to the accidental point terrestrial.

A thorough knowledge of perspective is a *sine quâ non* to the painter or designer, and though many are inclined to think it a superfluity, and that the sketcher has only to make use of his eyes and copy justly, the very fact that such is their opinion shows that they have never made the attempt; for it is impossible for the painter, and much more so for the designer, to execute a copy of nature with sufficient accuracy by the sole aid of the eye and hand, a fact that is unfortunately much too frequently proved by many of the sketches exhibited in fine-art collections. Perspective was known to the ancients, but seems to have become extinct during the disturbances that convulsed Italy, and was revived by Albert Dürer and Bramantino of Milan (*c.* 1470–1535), whose body of rules was extended and completed by Peruzzi and Ubaldi about 1600. Dr Brook Taylor in 1715 and 1719 was the first Englishman who discussed the subject scientifically.

There are works on perspective by Tyrwhitt (1868), Humphris (1869), Collins (1872), Dennis (1877), Pellegrin (New York, 1874), Burchett (1881), Miller (1887), and James (1888).

Perspiration. See Skin.

Perth, the county town of Perthshire, on the right bank of the tidal Tay, 43 miles NNW. of Edinburgh, 22 WSW. of Dundee, and 62 NE. of Glasgow. The beauty of its surroundings—the noble river; the two wooded heights, Moncreiffe and Kinnoull Hills, 725 and 730 feet high; and, away to the north, the Grampians—makes the 'Fair City' worthy of the name. A handsome nine-arch bridge (1772; widened 1871), 840 feet long, and stretching over a waterway of 590 feet, leads to the suburb of Bridgend, where Ruskin spent much of his childhood, on the east bank of the Tay; along the west bank extend two beautiful public parks, the North and South Inches, 98 and 72 acres in area. St John's Church, whose restoration was undertaken in 1891, is the only old building—a cruciform Decorated pile, with an earlier central square tower. Other edifices are St Ninian's Episcopal Cathedral (1850–90), an Early Middle Pointed structure, by Butterfield; the Tudor municipal buildings (1879), the Grecian county buildings (1819–67), the city hall (1844), the infirmary (1837–69), and the penitentiary and general prison for Scotland (1812–59), besides which may be noticed the water-works (1830–80), two museums, the Albert statue (1864), and the auction-mart (1875). Railways have largely diverted the river-trade; and dyeing is now the leading industry, with manufactures of ink, gauge-glasses, linen, iron, beer, &c. A royal burgh since 1210 or earlier, and taking precedence of all others save Edinburgh, Perth returns one member. Pop. (1831) 19,238; (1861) 25,250; (1891) 29,919.

Perth, or St Johnstoun, as it was formerly called, has a wealth of historic memories—the bloody combat on the North Inch between sixty members of the clans Chattan and Kay (1396); the murder of James I. (q.v., 1437); Knox's 'thundering sermon against idolatry' in St John's (1559); the Gowrie Conspiracy (q.v., 1600); and Montrose's victory of Tippermuir (1644); besides sixteen ecclesiastical councils and fourteen parliaments, and visits innumerable from royal personages, including both the Pretenders and Queen Victoria. James, fourth Lord Drummond, was in 1605 created Earl of Perth—a title forfeited in 1695 by the Jacobite fourth earl (titular Duke of Perth), and restored in 1853 to George Drummond, sixth Duc de Melfort.

The *Five Articles of Perth*, memorable in the ecclesiastical history of Scotland, were agreed upon in a meeting of the General Assembly, convened at Perth, by command of James VI. in 1618. They enjoined kneeling at the Lord's Supper, the observance of Christmas, Good Friday, Easter, and Pentecost, and confirmation, and sanctioned the private administration of baptism and of the Lord's Supper. Highly obnoxious to the Presbyterians as having been adopted in mere compliance with the king's will, they yet were ratified by the parliament, and enforced by the Court of High Commission. They became one of the chief subjects of that contention between king and people which produced results so grave and sad for both in the subsequent reign. The General Assembly of Glasgow in 1638 declared that of Perth to have been 'unfree, unlawful, and null,' and condemned the Five Articles.

See *Perth Memorabilia* (1806), Maidment's *Chronicle of Perth* (Maitland Club, 1831), and works by Penny (1836), Lawson (1847), Peacock (1849), and J. Wilson (1860).

Perth, the capital of Western Australia, occupies a picturesque site on the north bank of the Swan River, 12 miles from Fremantle, its port, at the mouth of the river. Perth is the headquarters of banking for the colony, and the centre of the principal railway lines, including the Great Southern Railway to Albany. The more important buildings are the town-hall, the Protestant (1888) and Roman Catholic cathedrals, churches, mechanics' institute and museum, and the governor's residence. Pop. (1881) 5044; (1890) 9617; (1895, estimated) 19,533, the rapid growth of late being accounted for by the gold discoveries in Western Australia (q.v.).

Perth, capital of Lanark county, Ontario, on the river Tay, 141 miles by rail WSW. of Montreal, contains mills and manufactories of machinery, leather, woollens, &c. Pop. 2467.

Perth Amboy, a port of entry of New Jersey, on the Kill van Kull, 26 miles by rail SW. of New York. There is a steam-ferry to Tottenville in Staten Island. Pop. (1885) 6311; (1890) 9512.

Perthes, Friedrich Christoph, German publisher, was born at Rudolstadt, 21st April 1772, learned his business in Leipzig, and started on his own account in Hamburg in 1796, and soon pushed himself into the front rank of German publishers. An ardent patriot, he in 1810 started the *National Museum*, with contributions from the most influential writers of the day, and took an active personal part in resisting the establishment of French authority in Hamburg and Germany. Having built up his business again during the first years of peace, he removed in 1821 to Gotha. There his greatest publication was the historical series of works on all European nations, edited by Heeren, Ukert, and Giesebrecht. He died at Gotha, 18th May 1843. See Life (6th ed. 1872; Eng. trans. 1878) by his son Clemens Theodor.—Johann Georg Justus Perthes (1749–1816), an uncle to Friedrich, established a publishing-house at Gotha in 1785, which has acquired in the hands of his sons a great reputation as a geographical institute; it issues *Petermann's Mitteilungen*, Stieler's *Atlas*, numerous books of travel and geography, and the *Almanach de Gotha*.

Perthshire, the fourth largest county of Scotland, bounded by Inverness, Aberdeen, Forfar, Fife, Kinross, Clackmannan, Stirling, Dumbarton, and Argyll shires. Its greatest length, from east to west, is 77 miles; its greatest breadth, from north to south, 68 miles; and till 1891 its area was 2601 sq. m., or 1,664,690 acres, of which 38,274 were water. In that year no fewer than eighteen alterations were made by the boundary commissioners, Perthshire receiving eight small enclaves from Forfar, Fife, Kinross, and Stirling shires, whilst giving off to the last three a like number, including the Culross and Tulliallan portion (13,125 acres). Partly Lowland, but mainly Highland (Strathmore the dividing line), it is called by Scott 'the fairest portion of the northern kingdom;' and such, indeed, it is, with its mountains and glens, its rivers and lakes, its forests and fertile vales. The chief rivers are the Forth and Tay, the former receiving the Teith, Allan, and Devon, the latter the Tummel, Lyon, Isla, Braan, Almond, and Earn; whilst amongst upwards of eighty lakes are Lochs Tay, Ericht, Earn, Rannoch, Lydoch, Katrine, Achray, Vennachar, and Menteith. In the south rise the Ochils, with Dunmyat (1375 feet) and Blairdenon Hill (2072); in the south-east the Sidlaw Hills, with Dunsinane (1012) and King's Seat (1235); and the Highland area is largely occupied by the Grampians, of whose forty-six summits exceeding 2300 feet may be mentioned Ben Lawers (with cairn, 4004), Benmore (3843), Ben-y-Gloe (3671), Schiehallion (3547), Ben Vorlich (3224), Ben Ledi (2875), Ben Vrackie (2757), and Ben Venue (2393). The soil is extremely varied, in places of great fertility—e.g. in Strathearn and in the Carse of Gowrie, which skirts the north side of the Tay's estuary; but barely a fifth of the entire surface is in tillage, the rest being pasture, woods, deer-forests, mountain, and desolate moorland, such as Rannoch. The woods cover nearly 100,000 acres; and the annual rental of the Perthshire deer-forests, grouse-moors, and rod- and net-fishings exceeds in some years £70,000. Ancient divisions were Athole (N.), Rannoch (NW.), Breadalbane (W.), Balquhidder (SW.), Menteith (S.), Perth (SE.), Gowrie (E.), Stormont and Strathearn (central). The county since 1885 returns two members, one for the eastern and one for the western division; and Perth itself is a parliamentary burgh. Other towns and villages are Aberfeldy, Abernethy, Auchterarder, Birnam, Blair-Athole, Blairgowrie, Callander, Comrie, Couper-Angus, Crieff, Doune, Dunblane, Dunkeld, Pitlochry, Scone, and Stanley. The Roman camp at Ardoch is a famous antiquity; and Perthshire contains the battlefields of the Grampians, Tippermuir, Killiecrankie, and Sheriffmuir; whilst it possesses memories of Bruce, Queen Mary, Rob Roy, Burns, Scott, Lady Nairne, Wordsworth, and Queen Victoria. The mansions, which are very numerous, include Taymouth, Drummond, and Blair castles. Pop. (1801) 125,583; (1831) 142,166; (1881) 129,007; (1891) 126,184, of whom 14,150 were Gaelic-speaking.

See separate articles on many of the above-named places; also works by Drummond (1879), Marshall (1880), Hunter (1883), and Millar (1890).

Pertinax, Helvius, Roman emperor, was born, according to Dio Cassius, at Alba-Pompeia, a Roman colony of Liguria, August 1, 126 A.D. He received a good education, and, entering the military service, rose through the various grades till he obtained the command of the first legion, at the head of which he signalised himself in Rhætia and Noricum against the native tribes. In 179 he was chosen consul, aided to repress the revolt of Avitus in Syria, and was governor successively of the provinces of Mœsia, Dacia, and Syria. The Emperor Commodus sent him to take the command of the turbulent legions in Britain, who against his will proclaimed him emperor; thereupon he solicited to be recalled, and was appointed pro-consul of Africa, prefect of Rome, and consul (a second time) in 192. On the death of Commodus his assassins almost forced Pertinax to accept of the purple, which with great hesitation he did; but, in spite of his promise of a large donation, he was unable to gain over the prætorian guard. His accession was, however, hailed with delight by the senate and people, who were rejoiced to have as ruler an able captain instead of a ferocious debauchee; and Pertinax, encouraged by this favourable reception, announced his intention of carrying out an extensive series of reforms, having reference chiefly to the army, in which he hoped to re-establish the ancient Roman discipline. Unfortunately for his reforms and himself, he was attacked by a band of the rebellious prætorians, two months and twenty-seven days after his accession, and, disdaining to flee, was slain, and his head carried about the streets of Rome in triumph.

Perturbations, in Physical Astronomy, are the disturbances produced in the simple elliptic motion of one heavenly body about another by the action of a third body, or by the non-sphericity of the principal body. Thus, for instance, were there no bodies in space except the earth and moon, the

moon would describe accurately an ellipse about the earth's centre as focus, and its radius-vector would pass over equal areas in equal times; but only if both bodies were homogeneous and truly spherical, or had their constituent matter otherwise so arranged that they might attract each other as if each were collected at some definite point of its mass. The oblateness of the earth's figure, therefore, produces perturbations in what would otherwise be the fixed elliptic orbit of the moon. Again, when we consider the sun's action it is obvious that in no position of the moon can the sun act equally upon both earth and moon; for at new moon the moon is nearer to the sun than the earth is, and is therefore more attracted (in proportion to its mass) than the earth—i.e. the *difference* of the sun's actions on the earth and moon is equivalent to a force tending to draw the moon away from the earth. At full moon, on the other hand, the earth (in proportion to its mass) is more attracted than the moon is by the sun; and the perturbing influence of the sun is again of the nature of a force tending to separate the earth and moon. About the quarters, again, the sun's attraction (mass for mass) is nearly the same in amount on the earth and moon, but the *direction* of its action is not the same on the two bodies, and it is easy to see that in this case the perturbing force tends to bring the earth and moon nearer to each other. For any given position of the moon, with reference to the earth and sun, the *difference* of the accelerating effects of the sun on the earth and moon is a disturbing force; and it is to this that the perturbations of the moon's orbit, which are the most important, and amongst the most considerable, in the solar system, are due. See MOON, PLANETS, &c.

Peru, a republic of South America, extending from near 2° to 17° 20′ S. lat. Previous to the annexations by Chili, the Peruvian territory stretched southward to 22° 10′, with a length along the Pacific coast of 1400 miles, and a width of 300 miles. It borders on the Pacific, Ecuador, Brazil, Bolivia, and Chili. The area is roughly estimated at 500,000 sq. m. There has been no census since 1876, but the population (believed to be stationary owing to infant mortality and other causes) was in 1895 stated at 2,730,000; the aboriginal Inca Indians forming 57 per cent., the *Mestizos* or half-castes 23 per cent., and the people of pure Spanish descent, negroes, Chinese, &c., 20 per cent. Peru is still the country of the Inca people.

Copyright 1891 in U.S. by J. B. Lippincott Company.

Surface of the Country.—The surface of Peru is extremely varied. It is divided longitudinally into three well-marked regions. (1) The *Coast* extends from the base of the Andes to the Pacific Ocean, and consists of a sandy desert crossed at intervals by rivers, along the banks of which there are fertile valleys. (2) The *Sierra*, or region of the Andes, about 250 miles wide, contains stupendous chains of mountains, elevated plains and tablelands, warm and fertile valleys and ravines. (3) The *Montaña*, skirting the eastern slopes of the Andes, is the third region. It consists of tropical forests traversed by great tributaries of the Amazon. The coast region has been upraised from the ocean at no very remote period. The absence of rain on this strip of land between the mountains and the sea is caused by the action of the lofty uplands of the Andes on the trade-wind. Reaching the snow-capped summits the last particle of moisture is wrung out of the wind that the very low temperature can extract, and it rushes down to the Pacific coast, cool and dry. Its moisture is deposited as snow on the tops of the cordillera, and feeds the mountain-streams which flow down to irrigate the coast-valleys. From November to April there is usually constant dryness on the coast, from June to September the sky is obscured for weeks by mist, sometimes accompanied by drizzling rain. The maximum temperature is about 78° in summer and 60° in winter. When it is hottest and driest on the coast it is raining heavily in the Andes, and the rivers are full. When the rivers are lowest mists and *garuas* or drizzling rains prevail on the coast. The deserts are divided from each other by forty valleys of great fertility, and the cultivable area on the coast might be considerably extended by irrigation. The coast has few protected anchorages, and the headlands are generally abrupt and lofty. This region is subject to frequent and severe earthquakes, the most destructive in modern times having been that of 1868, which nearly destroyed Arequipa and Arica, and that of 1877. Since 1570 there have been seventy destructive earthquakes recorded on the west coast of South America.

The Peruvian Andes contain peaks attaining heights of 21,000 and 22,000 feet; but they have never been measured with scientific accuracy. The mountain-system consists of three chains or *cordilleras*. Two of these chains, running parallel and near each other, are of identical origin. The western one is the maritime cordillera and comprises the volcanoes. The eastern cordillera is a magnificent and almost continuous range, in great part of Silurian formation, with clay-slates and eruptive granitic rocks. The western cordillera is cut through by several streams which flow into the Pacific, and the eastern cordillera by six tributaries of the Amazon, but the central chain is an unbroken water-parting. It consists mainly of crystalline and volcanic rocks, on each side of which are strata of aqueous, in great part of Jurassic, rocks. The valleys and plateaus between these ranges form the *Sierra* of Peru, and include every variety of climate and scenery. They may be divided, from a geographical point of view, into four sections, commencing from the north. The first, 350 miles long by 100 broad, comprises the upper basins of the Marañon and Huallaga. The second extends for 200 miles from Cerro Pasco to Ayacucho, including the lake of Chinchay-cocha and the valley of Janja. The third extends for 250 miles to the knot of Vilcañota, comprising the upper valleys of the Apurimac, the Vilcamayu, and the Paucartambo. Here is Cuzco, the capital of the Incas, the centre and heart of Peru. The fourth section is the basin of Lake Titicaca, about 150 miles in length and breadth. The lake itself is 80 miles long, and 12,545 feet above the level of the sea. A number of rivers, which are of considerable volume during the rainy season, fall into it, and it is drained by the Desaguadero flowing out of the south-west angle. But a great proportion of the water is also taken up by evaporation, and the waters are gradually receding. The Sierra of Peru is the original home of the potato. Its lofty heights also produce several other edible roots, and the grain called *quinua* (*Chenopodium quinua*), while splendid crops of maize are grown in the valleys. The animals which specially belong to the Peruvian Sierra are the domestic llamas and alpacas, and the wild vicuñas. The llamas were the beasts of burden in the time of the Incas, each carrying a weight of about 100 lb. Alpacas have always been prized for their long and soft wool, and are tended with great care, being kept in large flocks. The other animals of the Peruvian Sierra are the *taruco* or deer, two rodents called *viscacha* and *chinchilla*, a native dog, and a fox. The largest bird is the condor, and there is another bird of the vulture tribe called *alcomari*. Partridges, called *yutu*, and plovers are met with on the lofty plateaus. The large and handsome geese called *huachua* and

huallata, several ducks, a gull, flamingoes, and other wading-birds frequent Lake Titicaca and the banks of the rivers. In the valleys there are many kinds of finches, and a green parrakeet has been seen at a height of 12,000 feet above the sea.

The *Montaña* is the region of tropical forests within the basin of the river Amazon, including the wooded slopes of the eastern watershed of the Andes, which may be called the subtropical portion of the Montaña. This part of Peru is traversed by great navigable rivers. Here the Marañon and Huallaga, after separate courses of 600 and 400 miles respectively, unite and flow eastward to the Brazilian frontier. At 150 miles from their point of junction they are increased by the waters of the Ucayali, a great navigable river with a course of 600 miles. The forests drained by the Marañon, Huallaga, and Ucayali form the northern portion of the Peruvian Montaña. The southern half is watered by streams flowing down from the eastern Andes in the Sierra sections of Cuzco and Titicaca, and forming the Madre de Dios, a great tributary of the Bolivian river Beni, which has not yet been fully explored. The whole length of the Peruvian Montaña, from the Marañon to the Bolivian frontier, is 800 miles. In the subtropical portion, comprising the eastern slopes of the Andes, which sometimes extend for a distance of 60 or 80 miles before they subside into the Amazonian plain, there are very important products. This is the region of the quinine-yielding cinchona-trees, and of the coca (*Erythroxylon coca*), and here coffee and cacao of the finest quality are cultivated. From the forest-covered plains come india-rubber, sarsaparilla, and a great variety of useful and ornamental timber. The *fauna* of the forests is naturally much more numerous and varied than that of the Sierra. Here is the silver-gray monkey, the largest in South America, and other species. Bats of several kinds are numerous, and there are flocks of coatis. The Andean bear, called *ucumari*, is found on the upper borders of the forests. The puma also roams over the higher slopes, where he has an almost undisputed hunting-ground. Lower down there are jaguars, and several kinds of wild cats. Squirrels and other rodents swarm, and the heavy tapir, called *danta* or *gran bestia*, reposes in the soft marshy lands. Deer frequent the open ground, and herds of peccaries traverse the forests. The chief game-bird is the large black curassow, and there are several pigeons. Spoonbills, ibis, cranes, snipe, and curlew frequent the lagoons, while parrots, toucans, and other birds of bright plumage are innumerable. Snakes abound among the dense underwood, frogs raise their far-sounding voices through the night, and insects swarm in myriads. But the knowledge of the fauna of the Peruvian forests is still very incomplete.

Productions and Commerce.—The chief crops of the fertile valleys on the coast of Peru are sugar, cotton, and grapes. The exportation of sugar amounted to 45,000 tons in 1889, but it was double that figure in 1879, previous to the disastrous war with Chili. Peruvian cotton is chiefly grown in the valleys of Piura and Ica, and is a perennial. In 1889 the quantity of cotton exported from Piura and Ica was 2,946,400 lb. The vine has been a profitable industry ever since the Spanish conquest, in several valleys on the coast, and also in the Sierra. Good wine is made at Pisco and Ica, and also a famous spirit from the grape, called *Pisco* and *Italia*. The yield of wine in 1889 was 17,600,000 pints, and of spirits 5,280,000 pints. Rice of excellent quality is raised in the coast-valley of Lambayeque, and there are establishments for preparing it at Lambayeque and Ferreñafe. In 1889 the crop was 24,750,000 lb. Olives are grown in the Tambo valley near Arequipa, and before the Chilian war mulberries, silkworms, and cochineal were successfully cultivated. The rocky islets and barren deserts of the coast were once a source of enormous wealth to Peru, but are so no more. The exportation of Guano (q.v.) from the Chincha Islands began in 1846 and ended in 1872, the supply being exhausted; and the nitrates of Tarapacá were seized and annexed by Chili, as the result of the war.

The staple exports of the Sierra of Peru are silver and wool. The silver-mines extend along the whole length of the cordilleras, and are worked here and there, the great centre of mining industry being at Cerro Pasco. In 1877 the Cerro Pasco mines produced 1,427,592 oz. of silver, and there are others of equal value round Puno, in the south of Peru. In the above year the value of exported silver was £575,000; of copper, £330,000. Up till 1891 there were no later returns; in 1894 the total mineral output was valued at £450,000. There are rich gold-washings in the Caravaya province.

Mollendo is the principal port for the export of wool; but wool is also shipped from Salaverry, Pacasmayo, and Chala. There are no reliable returns of the quantity and value. From the Montaña the exported products are cinchona bark, coca (of which 3044 lb. of leaves were exported in 1889), coffee of the finest quality, cacao, tobacco, india-rubber, sarsaparilla, and some other medicinal roots. Maize is also exported to Chili, and large quantities of wheat are imported from Chili and the United States.

Public Works.—The system of railways consists of a dozen short lines in the coast-valleys—varying in length from 80 to 20 miles, constructed to bring the produce down to the seaports—and of two long lines across the Andes. The first of these, from Callao and Lima to Oroya, in the lofty valley of Jauja, is to be 136 miles long, and was commenced in 1870. It threads the intricate gorges of the Andes by a winding path along the edges of precipices, through tunnels, and over bridges that seem suspended in the air. It tunnels the Andes at an altitude of 15,645 feet, and the bridge of Verrugas (q.v.), finished in 1891 in succession to one destroyed by a flood in 1889, is 250 feet high, and spans a chasm 580 feet wide. Of this railroad 87 miles had been completed at a cost of £4,625,887. The other great line across the Andes connects the port of Mollendo with Puno on the shores of Lake Titicaca, passing by Arequipa. The summit is crossed at a height of 14,660 feet, and the line is 346 miles long. In 1874 steamers were first launched on Lake Titicaca. In order to supply the port of Mollendo with water a pipe has been laid alongside the line from Arequipa for a length of 85 miles, discharging 433,000 gallons in twenty-four hours—the longest iron aqueduct in the world. The construction of these great public works, chiefly between 1868 and 1872, involved the finances of Peru in grave difficulties. Previously the debt, mainly incurred during the war of independence, was £4,400,000, the interest of which was paid from the proceeds of the guano. But by 1872 the debt had been increased to £49,000,000, requiring an annual sum of £2,450,000 to pay the interest. The payment of interest was suspended from 1876 till 1896, having been paid since 1849. The financial difficulties culminated with the disastrous war with Chili, when the nitrate of Tarapacá, the chief resource of Peru, fell into the hands of the enemy.

The People.—The bulk of the Peruvian population is composed of the aboriginal Inca Indians, whose language, called Quichua, is still spoken in the Sierra. The Incas had attained to a high state of civilisation before the arrival of the Spaniards. They cultivated many of the arts, and had some knowledge of astronomy. They had domesticated

the llamas and alpacas, had brought under cultivation maize and quinoa, potatoes and many other edible roots, understood mining and the working of metals, and excelled as masons, weavers, potters, and farmers. They brought the science of government to a high pitch of perfection. The Incas composed songs and dramas; and as soldiers their skill and prowess enabled them to conquer and consolidate a vast empire. Three centuries of oppression under Spanish rule have deteriorated the character of the Inca Indian, but he is still industrious and honest, and retains some of the virtues of his ancestors. The wild Indians of the Montaña were never subjugated by the Spaniards. Spanish administration caused a rapid diminution of the population. The Indians of the Sierra were decimated, while those of the coast-valleys disappeared altogether. Negro slaves were then introduced to cultivate the estates in the coast-valleys, and this system continued during Spanish colonial rule, and until 1855. In that year slavery was abolished, and the emancipation of the negro population gave rise to difficulties in obtaining labour. Chinese immigration schemes were resorted to, and from 1860 to 1872 as many as 58,646 Chinese coolies were imported.

Civil Divisions, Cities, and Towns.—Peru is divided into departments, which are subdivided into provinces. On the coast, commencing from the north, the departments are Piura, Lambayeque, Libertad (formerly Trujillo), Ancachs, Lima, Ica, and Arequipa. The capital of Piura is San Miguel de Piura, founded by Pizarro, with a seaport called Payta at a distance of 63 miles. The next department of Lambayeque has a capital of the same name, with three small seaports of San José, Eten, and Pimentel. Libertad has the episcopal city of Trujillo as its capital, which was founded by Pizarro in 1535. The seaports are Huanchaco, Salaverry, and Huañape. Ancachs does not contain any city of note. Lima (q.v.), the capital of Peru, is nearly in the centre of the coast region, and has a population of almost 200,000. The department of Ica, south of Lima, is composed of the two provinces of Ica and Chincha, each with a city, and has its principal seaport at Pisco. Arequipa was for sixteen years the most southern department of Peru, Tacna and Arica being occupied by the Chilian invaders. Besides Mollendo (107 miles by rail from the city of Arequipa), it also has small ports for export at Islay, Quilca, and Chala.

The departments of the Sierra of Peru are Cajamarca, Huanuco, Junin, Huancavelica, Ayacucho, Apurimac, Cuzco, and Puno. Five of these have provinces also in the Montaña; and there are two departments, those of Amazonas and Loreto, entirely in the Montaña. On the coast the houses are built of *adobes* or large sun-dried bricks, and are flat-roofed. In the Sierra the houses are generally of stone, with high-pitched red-tiled roofs. The most northern department contains the cities of Cajamarca and Jaen. Huanuco has a capital of the same name. Junin contains the mining-town of Cerro Pasco, and the cities of Tarma, Jauja, Concepcion, and Huancayo. Huancavelica is a mountainous department, and its chief town owed its existence to the proximity of a quicksilver-mine. Ayacucho received its name from the battle in which Peru gained her independence. Its chief city of Guamanga, now called Ayacucho, was founded by Pizarro in June 1539. The Apurimac department comprises the two valleys of Andahuaylas and Abancay. Cuzco is the central department of the Sierra of Peru. Its capital was formerly the capital of the Inca empire, and the cathedral and other churches are raised on the palaces of the Incas. A few miles from Cuzco is the warm and fertile valley of the Vilcamayu, containing the delightful towns of Urubamba, Calca, Sicuani, and Tinta. The department of Puno comprises the basin of Titicaca and the rich province of Caravaya in the Montaña. Its capital, on the north-western shore of the lake, owes its origin and former prosperity to the rich veins of silver ore in the surrounding hills. The other cities of the department are Lampa and Chucuito.

Church and Education.—When the Spaniards conquered Peru the Catholic religion was enforced on all natives, and a determined attempt was made to crush out the modes of thought, traditions, and culture of the Inca civilisation, and to substitute new ideas and beliefs. This destructive system was resolute and well organised, and was in great part successful. Education and literature were in the hands of an intolerant priesthood. The cruel Friar Valverde was made Bishop of Cuzco in 1534. The archbishopric of Lima was created in 1541, and the bishoprics of Guamanga, Arequipa, and Trujillo were added in 1612 and 1614. Swarms of clerics followed the bishops, numerous monasteries were founded, and an inquisitorial system of catechising and punishing penetrated into every village and hamlet in the land. Schools were established in the towns for the education of young Spaniards and half-castes; and the university of San Marcos at Lima, the most ancient in the New World, was founded in 1551. It had professorial chairs of medicine, philosophy, rhetoric, Latin, mathematics, divinity, and for a short time of Quichua—the language of the Incas. In 1793 there were 313 doctors of San Marcos. The college of San Carlos at Lima, which still flourishes, was founded in 1770, and the school of medicine was established in 1792. At Cuzco the university of San Antonio Abad was founded in 1598, and the viceroy, Prince of Esquilache, also endowed the college of San Borja there, for the education of noble Indians. At Arequipa the college of San Geronimo was founded in 1616, for teaching Latin and theology, and similar colleges were founded at Trujillo in 1621 and at Guamanga in 1680. These universities and colleges produced historians and other writers of eminence, the best known in Europe being Dr Peralta y Barnuevo, who wrote *Lima Fundada*, and Leon Pinelo, the author of a well-known bibliography. In later times, and since the independence, Peru has produced numerous meritorious writers, including the learned Dr Vigil, the antiquary Rivero, the historians Lorente and Palma, the geographers Paz Soldan and Unanue, the poets Marquez, Althaus, and 'Juan de Arona,' and the biographer Mendiburu. Additional colleges have been established in the large towns, and numerous schools in the villages, within the last fifty years. Besides the university of Lima, there are two lesser universities at Cuzco and Arequipa. There are high schools maintained by government in the capitals of the departments. Education is (nominally) compulsory for both sexes, and is free in the municipal public schools, yet but a fraction of the population has attended any school.

History.—From very ancient times there were agricultural communities in the Sierra of Peru, gradually advancing in the arts of government and of peace, and there were people of a different race in the coast-valleys, who were also civilised. The plants they had brought under cultivation, and the animals they had domesticated, are among the proofs of the great antiquity of Peruvian civilisation. Eventually all the different communities were united under one empire, and the Incas, in the course of some five centuries, developed a highly centralised system of government. Civilisation never attained to such a height among any other of the indigenous races of America. The Incas attempted the administra-

tion of a purely socialistic government, and their attempt was successful. The great Inca Huayna Capac died, after a long and prosperous reign, at about the time when Pizarro first visited Tumbez. On his death there was a war of succession between his two sons, which had just terminated in favour of Atahualpa when Pizarro (q.v.) landed a second time and marched into the interior. Peru was soon overrun by the Spaniards, and the beneficent rule of the Incas came to an end. At about the time of the assassination of Pizarro the representations of Las Casas (q.v.) respecting the cruel treatment of the Indians had obtained a hearing, and the 'New Laws' were promulgated. The grants conceded to the conquerors were not to be hereditary, all men who had been engaged in civil wars were to be deprived, and personal service from Indians was forbidden. Blasco Nuñez Vela was sent out to Peru as viceroy to enforce these reforms. He landed in 1544, and proclaimed the 'New Laws.' The Spanish conquerors were thrown into a state of exasperation and dismay, and appealed to Gonzalo Pizarro (q.v.) to leave his retirement and protect their interests. The result was that the viceroy was defeated and killed, and Gonzalo virtually became governor of Peru. But he was not recognised by the Spanish government, and an ecclesiastic named Pedro de la Gasca was despatched to Peru, with a commission to restore order. Gonzalo Pizarro was defeated near Cuzco, and beheaded on the battlefield. Gasca reversed the humane legislation advocated by Las Casas, and made a hasty distribution of grants to his followers. The announcement of his awards caused much discontent, but Gasca hurriedly sailed for Spain in January 1550, leaving the country in a most unsettled state, in the hands of the four judges who were his colleagues. He had arranged that the emperor's decree against forced labour should be promulgated after he was safe out of the country. This gave rise to a formidable rebellion, led by Francisco Hernandez Giron. The judges made head against it, but it was not put down until two pitched battles had been fought, and Giron had been beheaded at Lima in December 1554.

The Marquis of Cañete arrived as viceroy of Peru in May 1555. His policy was to employ the unquiet spirits among the Spanish settlers on expeditions of discovery into unknown regions, and to treat the natives with liberality and justice. During the five years of his government he restored order among the conquerors, and established the heir to the Incas in a dignified retirement. But it was Don Francisco de Toledo, the viceroy from 1569 to 1580, whose legislation finally fixed the colonial policy of Spain in this part of the New World. He reversed the kindly treatment of the ancient dynasty which had distinguished the Marquis of Cañete, and unjustly beheaded young Tupac Amaru, the last of the Incas, at Cuzco in 1571. At the same time he wisely based his legislation on the system of the Incas. His elaborate code, called the 'Libro de Tasas,' was the textbook of all future viceroys. He fixed the amount of tribute to be paid by the Indians, exempting all males under the age of eighteen and over that of fifty. He recognised the position of the native chiefs, assigning them magisterial functions, and the duty of collecting the taxes and paying the money to the Spanish officials. But he enacted that one-seventh part of the population of every village should be subject to forced labour, generally in the mines. This was called the *Mita* system.

It was the habitual infraction of the rules established by Toledo, and the abuse of the *Mita*, which caused all the subsequent misery and the depopulation of the country. Compliance with the continual demand for treasure from Spain, a demand which was insatiable, was incompatible with humane treatment of the people. For more than two centuries the people of Peru toiled and died. At length their sufferings became intolerable. They rose as one man in the autumn of 1780, and a descendant of the Incas, taking the revered name of Tupac Amaru, placed himself at their head. After a long and formidable resistance the insurgents were finally subdued, and their leader was put to death under circumstances of revolting cruelty. But he did not die in vain. In his fall he shook the colonial power of Spain to its foundation. From the cruel death of the Inca Tupac Amaru may be dated the rise of that feeling which ended in the expulsion of the Spaniards from South America. Some of the demands of the Inca were conceded soon after his death. He was the foremost pioneer of the independence of Peru. The desire for liberty among Peruvians of Spanish descent had its birth in Lima; but Lima was the residence of the viceroy. Here the power of Spain was concentrated. Consequently it was in the more distant colonies of Buenos Ayres, Carácas, and Chili that insurrectionary movements first broke out and that independence was first secured.

At length a fleet under Lord Cochrane (see DUNDONALD), equipped in Chili, brought the Argentine General San Martin to Peru with troops, and the independence of the land of the Incas was proclaimed at Lima on the 28th of July 1821. Another liberating force, from Colombia, under General Bolivar, embarked at Guayaquil, and when the Liberator arrived at Lima, in September 1823, San Martin retired. The Spanish viceroy, La Serna, with his army, retreated into the interior, and the patriots followed on his heels. On 9th December 1824 the decisive battle of Ayacucho was fought, the Spanish viceroy and all his officers were made prisoners, and the colonial government finally gave place to a free republic. Bolivar and his Colombians left the country in 1826, but it was eighteen years before the government became settled. In August 1829 General Gamarra, a native of Cuzco and a hero of Ayacucho, was elected president of Peru, but at the end of his term of office there were troubles which culminated with an attempt to form a Peru-Bolivian Confederation under General Santa Cruz. This was defeated by Peruvian malcontents, aided by a Chilian army, the cause of Santa Cruz and his confederation having been ruined after the decisive battle of Yungay on January 20, 1839. Gamarra again became president, the confederation was dissolved, and a constitution was proclaimed. But Gamarra fell in a deplorable war with Bolivia, and the contentions of his officers caused a succession of civil wars until 1844.

At length a man arose who restored peace to the distracted country. Ramon Castilla was a native of Tarapacá, and was a veteran of Ayacucho. He was brave as a lion, prompt in action, and beloved by his men. His firm grasp of power secured a long period of peace. He was elected constitutional president of Peru in 1844, and ten years of peace followed. Castilla commenced the payment of interest on the foreign debt in 1849. A revised constitution was promulgated in 1856, and the slaves were emancipated. Castilla retired from office in 1862, and died in 1866. The next important event was the election of Colonel Balta. This president held office from 1868 to 1872, during which time public works were undertaken on a gigantic scale with the aid of foreign loans. Don Manuel Pardo, a scholar and a man of letters as well as a statesman, was the first civilian president. He held office from 1872 to 1876, and inaugurated a policy of retrenchment. But it was too late to save the credit of the state, and the payments of

interest on the loans ceased in 1876. Pardo reduced the army, regulated the Chinese immigration, promoted the exploration of navigable rivers in the Montaña, organised an efficient plan for the collection of statistics, and actively encouraged literature and education. He was the best president Peru has ever known, and in August 1876 he was peacefully succeeded by General Prado.

In 1879 Peru was confronted with the overwhelming misfortune of a Chilian invasion. Chili coveted the possession of the nitrate deposits in the Peruvian coast province of Tarapacá. A successful defence of Peru depends on the mastery of the sea. Peru had two old-fashioned ironclads. Chili also had two, but of new construction and with thicker armour-plates. One of the Peruvian ironclads was shipwrecked. The other, commanded by the heroic Admiral Grau, a native of Piura, was captured, after a most gallant defence, maintained against the combined attack from the two Chilian ironclads. On the 8th October 1879 he and nearly all his officers fell in defence of the *Huascar*, the ship on which the fate of their country depended. Tarapacá was occupied after the loss of two well-contested battles. In 1880 the battle of Tacna sealed the fate of that department; and, after the two desperate battles of Chorillos and Miraflores in 1881, Lima itself was occupied by the Chilians. Public works were demolished and private estates devastated along the coast, while in the capital the invaders even destroyed the valuable public library. General Caceres still kept up a patriotic resistance to the invaders in the interior.

In the autumn of 1883 the Chilians induced one of the Peruvian leaders, named Iglesias, to submit to their terms. In October he signed a treaty of peace and was allowed to enter Lima. Tarapacá was ceded to Chili; Tacna and Arica were to be held by Chili for ten years, after which a popular vote should decide whether they were to belong to Peru or Chili, the country chosen paying the other $10,000,000; and there were some articles, favourable to Chili, respecting the guano-deposits. The Chilians evacuated Peru in August 1884, and their nominee, Iglesias, followed them in December 1885. On 3d June 1886 General Caceres, who had gallantly defended his country against the Chilians from first to last, became constitutional president of Peru. His policy was retrenchment and the protection of the Indian population. Payment of interest of the foreign debt had become impossible. But a scheme was arranged in 1890 by which the foreign bondholders formed themselves into a company to receive all the railways for a term of sixty-six years, with mining, emigration, and other privileges. In return the company is to complete the railway system, and cancel the debt through the profits. Peru was slowly recovering from the disastrous effects of a great calamity, when in 1894–95 another insurrection broke out, and a new government was established. In 1898 no steps had been taken for the retrocession of Tacna and Arica, the negotiations as to the method of voting having fallen through.

For the history of the Incas and their civilisation, see the works of Cieza de Leon, Molina, Balboa, Garcilasso de la Vega, Montesinos, and Acosta, all, except Montesinos, translated into English for the Hakluyt Society; also Rivero's *Antigüedades Peruanas* (with Von Tschudi, Vien. 1851), of which an English translation appeared afterwards at New York; and the histories of Robertson, Lorente, Prescott, Helps, and Winsor (vol. i.), and the travels of D'Orbigny, Squier, Wiener, and Reiss and Stübel. For the Conquest, see, besides Robertson, Prescott, and Helps, the narrative of Xeres, Pizarro's secretary (Eng. trans. Hakluyt Soc.), and the writings of Herrera, Gomara, Zarate, Pedro, Pizarro, and Fernandez. For the period of the viceroys, see Figueroa's *Life of the Marquis of Cañete*, the *Chroniele of Calancha*, and the *Memorias de los Vireyes;* also the more recent works of Don Ricardo Palmas, published at Lima, and Saldamando's *History of the Jesuits in Peru*. The documents relating to the great rebellion of Tupac Amaru were published by Angelis at Buenos Ayres, and there are further particulars in the work of Dean Funes; see also Weddell's *Voyage dans le Nord de Bolivie*, and Markham's *Travels in Peru and India* (1862). For the war of independence, see works by Stevenson, the Chilian author Vicuña Mackenna, General Garcia Camba, the Memoirs of General Miller (Lond. 1828), the Autobiography of the Earl of Dundonald, and the great biographical work of General Mendiburu; for the war with Chili, narratives from the Chilian point of view by Barros-Arana and Mackenna, and from the Peruvian by Paz Soldan, and the present writer's *History of the War between Peru and Chili* (1883). For the geography, the *Geografía del Peru*, by Paz Soldan, and the 3 vols. on Peru by Raimondi are important works. There are further English works on Peru by Hill (1860), Hutchinson (1874), Duffield (1877), Guillaume (1888); French works by Grandidier (1863) and Chérot (1876); and German works by Wappäus (1864), Tschudi (1866), and Middendorff (3 vols. 1894–95). See also Von Tschudi's *Kechua Sprache* (1853), the present writer's *Quichua Grammar and Dictionary* (1863), Middendorff, *Die Einheimischen Sprachen Peru's* (1890 *et seq.*), and the present writer's *History of Peru* (Chicago, 1892).

Peru, (1) a city of Illinois, at the head of navigation on the Illinois River, 100 miles by rail WSW. of Chicago. It contains zinc-works, a foundry, a plough-factory, and several ice-houses. Pop. (1880) 4632.—(2) Capital of Miami county, Indiana, on the Wabash River, and on the Wabash and Erie Canal, 75 miles by rail N. of Indianapolis. Its mills and factories produce woollens, bagging, furniture, basket-ware, &c. Pop. (1890) 6731.

Perugia, a city of Italy, stands (1706 feet above sea-level) on the right bank of the Tiber, 11 miles E. of the lake of Perugia (anc. *Lacus Trasimenus*) and 127 miles by rail N. of Rome. It is surrounded with walls pierced by gates (one of them very old). The broad Corso, which contains the handsomest edifices, unites two squares, in one of which stands the Gothic cathedral of St Lawrence, dating from the end of the 15th century, and adorned with many paintings, carvings, &c. The church of St Dominic (1632) contains the tomb of Pope Benedict XI. by Giovanni Pisano, and stained windows (1402); the remarkable church of St Peter (11th century) has granite pillars, and pictures by Raphael, Perugino, Parmigiano; these are only two out of several noteworthy churches. In the cathedral square stand also the Gothic municipal palace (1281), with the valuable art gallery, especially rich in productions of the Umbrian school; the great fountain, adorned with statues by Niccolo and Giovanni Pisano; the statue of Pope Julius III. (1555), described in N. Hawthorne's *Marble Faun;* and the old money-changers' hall (1453–57), decorated with some of Perugino's best works. In the vicinity of the city a number of Etruscan tombs were discovered in 1840; they contained cinerary urns, lamps, vases, bronze armour, ornaments, &c. The university (1307) has 20 teachers and 130 students, a botanical garden, an observatory, a valuable antiquarian museum, and a library (1852) of 30,000 vols. There is also an academy of fine arts, with an art school. Silk and woollen goods, wax-candles, and liqueurs are manufactured. Pop. (1881) 17,395. Perugia, the ancient *Perusia*, was one of the twelve Etrurian republican cities. It was besieged and captured by the Romans in 310 B.C., and again in 40 B.C., and by Totila (549). At different periods during the next thirteen centuries it was subjected to the popes, especially after the middle of the 16th century; at other times it was independent, though in the power of native despots. In the 15th century it became the centre of the Umbrian school

of painting. In 1860 it was made a part of the kingdom of Italy.

Perugia, LAKE OF. See TRASIMENE LAKE.

Perugino, a celebrated Italian painter, whose real name was PIETRO VANNUCCI, was born at Citta della Pieve in Umbria, in 1446, but established himself in the neighbouring city of Perugia, whence his usual appellation. Vasari says he studied under Verrocchio at Florence. He executed important works, no longer extant, at Florence, Perugia (1475), and Cerqueto (1478). At Rome, whither he went about 1483, Sixtus IV. employed him in the Sistine Chapel; his fresco of 'Christ giving the Keys to Peter' is the best of those still visible—others by him being destroyed to make way for Michelangelo's 'Last Judgment.' During his next sojourn at Florence (1486–99) he had Raphael for his pupil. Here he was fined for waylaying and assaulting a citizen, and became somewhat too fond of money, repeating his works and leaving much of the execution to pupils. At Perugia (1499–1504) he adorned the Hall of the Cambio, with the assistance of Raphael and other pupils; but after 1500 his art visibly declined. In his second Roman sojourn (1507–12) he also, along with other painters, decorated the Stanze of the Vatican; and one of his works there, the Stanza del Incendio, was the only fresco spared when Raphael was commissioned to substitute his works for those formerly painted on the walls and ceilings. The new school, with Leonardo da Vinci, Michelangelo, and Raphael, was now in the ascendant, and Perugino's popularity waned. He was again at Perugia in 1512, and painted a number of pictures there. He was painting frescoes in a church at Castello di Fontignano, near Perugia (one of which frescoes is now at South Kensington), when he was seized by the plague, of which he died in 1524.

Perugino's art was religious, though he is said by Vasari (biased in all regards by Michelangelo's contempt for Perugino) to have been an open disbeliever in the immortality of the soul. In his figures, very unequally drawn, there is a peculiar tenderness of expression verging on mawkishness; his execution was delicate, his colour admirable. But he is not remarkable for originality or intensity.

Peruvian Bark. See CINCHONA.

Peruvian Gooseberry. See WINTER-CHERRY.

Pes'aro (the ancient *Pisaurum*), a town of Italy, stands on the right bank of the Foglia, here crossed by a bridge of Trajan's age, 1 mile from the Adriatic and 37 miles NW. of Ancona by rail. Its streets are broad, and adorned with palaces and churches, and the town is surrounded with walls and defended by a citadel (1474) and a fort. It is a bishop's seat; there are two cathedrals, one new, the other old. Silks, pottery, iron, and leather are manufactured; and an active trade is carried on in these goods and in wine, olive-oil, and fruits. Pop. 12,547. The city is associated in literary history with the name of Tasso, some of his MSS. being preserved in one of the town museums; it is also the birthplace of Rossini. Made a Roman colony in 184 B.C., it was destroyed by the Goths; then, having been rebuilt by Belisarius, it became one of the Pentapolis. From 755 to 1285 it belonged to the popes, then to the Malatestas till 1445, then to the Sforzas and Delle Roveres, in 1631 again to the popes, and finally in 1860 to Italy.

Pescadores Islands. See FORMOSA.

Peschiera, a fortress of Italy, a member of the Quadrilateral (q.v.), stands partly on an island in the Mincio and partly on the right bank of that river, at its outlet from the Lake of Garda, 14 miles by rail W. of Verona and 77 E. of Milan. Besides a strong citadel and an arsenal, there is a fortified camp. The fortress has played a prominent part in the warlike events which have taken place in North Italy, especially after the Napoleonic wars began down to 1859. Pop. 1653.

Peshawar, or PESHAWUR, a town of India, 10½ miles from the entrance of the Khyber Pass, 190 E. by S. of Kabul, and 276 by rail NW. of Lahore. Although a frontier town and occupying a strategic position of the utmost importance, its only defences are a mud wall and a small fort; but 2 miles west of the city are the cantonments, with a garrison of six regiments and a battery of Royal Artillery. The population in 1891 was 84,191, including the cantonments. Peshawar is the seat of extensive commerce between Afghanistan and India; gold, silver, lace, hides (all four from Bokhara), horses, mules, fruits, woollen and skin coats (all five from Kabul) being exchanged for tea, English piece-goods, wheat, salt, rice, butter, oil-seeds, oil, and sugar.—The *district* has an area of 2504 sq. m. and a pop. of 592,674; the *division*, an area of 8381 and a total pop. of 1,189,462.

Peshito (Syriac *pĕshittâ*, 'the simple'), the Syriac Vulgate. See BIBLE, Vol. II. p. 126.

Pessimism is the doctrine that on the whole the world is bad rather than good. It does not necessarily mean that the world is the worst possible of all conceivable worlds, as the fact of its being the verbal opposite to Optimism, the term employed to describe the Leibnitzian philosophy, would seem to imply; it means simply that the world is so bad that it would be better if it did not exist. Pessimism presents itself in a twofold aspect—(1) as a settled attitude of mind or permanent mood of feeling, and (2) as a philosophical system. The former springs out of the contemplation of the antagonism that exists in the world between natural laws and moral laws, between the world as it actually is and the world as it ought to be; it is the outcome of reflection, and is largely conditioned by individual temperament. Thus it is coeval with the dawn of conscious intelligence, and early found fit literary expression. The problem of the existence of evil, the connection between suffering and sin, is the burden of the ancient Hebrew Book of Job; and the Jewish thinker who wrote Ecclesiastes rings the changes upon the nothingness of life, and sums up his plaint in the hopeless refrain, 'Vanity of vanities, saith the Preacher, all is vanity.' Different forms of the same temper of mind are given utterance to with more or less of moral indignation in Innocent III.'s *De Miseria Humanæ Conditionis*, and the satirical works of Juvenal and Carlyle and others. The same 'world-sadness' (*Weltschmerz*), though expressed in more personal and passionate language, colours deeply the poetry of Omar Khayyam, Leopardi, Heine, and Byron; and the negation of the problem, 'Is life worth living?' forms an undercurrent in much of our best modern literature. But the pessimistic temper, culminating in the persuasion of the nothingness and vanity of human life, has had more than an individual expression; it has entered deeply into the substance and structure of two of the world's greatest religious beliefs—viz. Christianity and Buddhism. The Christian is familiar with the doctrine that this earthly life is a vale of tears and woe, and that its pleasures and joys are illusory, being always accompanied with sin and suffering and evil, from which he can only escape by fixing his hopes upon a better life in the world to come. Buddha's practical teaching (see BUDDHISM) turns in great part upon the desire to escape from the sorrows of life and the deceptive illusions of existence (*maya*).

But here, in this latter point, the pessimistic

mood assumes something of a philosophical character. It also enters, though principally as an unconscious element, into the philosophical doctrines of the Stoics and the Neoplatonists, in that they regarded man's sensual (sense) nature as opposed and inferior to his intellectual. The mediæval mystics (Eckhart) combined the religious with the philosophical tendencies of the mood that 'despiseth the earth,' but not in a conscious, deliberately philosophical fashion. But it is only in the most recent times that pessimism has been elaborated into a philosophy or complete theory, in the systems of Schopenhauer (q.v.) and his successor, E. von Hartmann (q.v.). Schopenhauer is generally considered to be the father of philosophical pessimism: he regards the world principle as an omnipotent, blindly struggling and striving Will, which is incapable of satisfying itself or of delivering itself from its eternal cyclic misery. Hartmann formulates as world principle the Unconscious, whose primal error, for which it eternally atones in the endless misery of the world, was its kindling—just as Schopenhauer's Will did—a light for itself in the brain, or the consciousness of organised life. Both philosophers build on the pain and misery and struggle which they see everywhere in the world, from chemical decomposition and stellar movement up through the endless struggle of organisms for existence to the acute suffering exhibited in the many forms of human passion, and chiefly of all in exalted passionate love or sexual desire (*Romeo and Juliet*, or *Kabale und Liebe* of Schiller); and to both all this is only the outward expression of the terrible, irrational, or non-logical cosmic agency. It is extremely difficult to state shortly the metaphysical grounds of pessimism; they are far from being merely superficial, and may be said to be rooted in the old antitheses between nature and man. Nature thwarts man at all points, and modern science has shown us what a small twig human life is on the great tree. Both Schopenhauer and Hartmann lay a firm hold on the fact (emphasised especially by Schopenhauer in opposition to Hegel and to theism) that not only the Idea or Logos must be used in replanning the world, but also Force, Impulse, Will, Strife. Thus in a sense they represent the substitution of the scientific or cosmic attitude towards the world for the merely introspective attitude of a Descartes or a 'common-sense' moralist. It is not, of course, in the least to be assumed that what we call 'naturalism,' as opposed to speculation or supernaturalism, leads to pessimism, mental and spiritual facts being just as ultimate as chemical protoplasm. The full force of pessimism lies in the assertion that all the ends and aims of life are illusory, that life, in fact, brings only illusion; the illusion of illusions being man's innate and inveterate belief that he is born to be happy and to have pleasure. There are here two main contentions: (1) All ends are illusory, even cosmic ends, for nothing is ever attained in the world, seeing that the essence of the world—that which holds it together—is strife and change. Pessimism, that is, really denies teleology, as Darwinism does, in the old sense of the term. (2) In the case of the individual life there is excess of unhappiness and pain over happiness and pleasure. But there is no reason for despising the realisation of certain ends because there always arises a limitless number of new ends to be realised; of course we do not wish to limit the world process. Pessimism thus really comes to stake its case on the individual, which (let us say) to a certain extent we do immediately know. The natural man wants to fill infinity, to gratify all his desires, to embrace in himself all the ends of the world, and because he cannot do this, but even fails to get immediate ends gratified, he votes the world execrable. The pessimists in the end do not escape the all-embracing human standpoint of anthropomorphism, anxious though Schopenhauer is to avoid the errors of metaphysicians and 'transcendental idealism.' They examine man, and what they find to be true of man they predicate of the world: he 'measures' all things—is the microcosm. Still, we must concede that, if to man the world brings only illusion, it is a failure—for him. The central position, then, of pessimism inevitably comes to be that living beings have as matter of fact an excess of pain over pleasure.

To this position the psychologist answers: (1) That pleasure and pain are not things that can be balanced one against the other. Both are *degrees* of *feeling*, which, though itself a constant element of experience, is only one element; and what we do as matter of fact measure and are conscious of is the amount of change or transition in our feeling, there being of course no absolute measure of amount of pleasurable or painful feeling. (2) Even if by the help of memory and calculation, and observation and reflection (for there is really enormous difficulty in the matter), we allow ourselves to think of sums of pleasures and sums of pains (there are writers who say the phrases are the purest nonsense), yet no one standard of pleasurableness or painfulness, no 'hedonistic calculus' or universal method of measuring pain against pleasure, can be fixed upon. (3) Even supposing we had an estimate of pleasures and pains, it is not psychologically legitimate to regard feeling of any kind as the *end* of action; it is only its relative and individual index or measure (i.e. whether normal or abnormal), while there are absolute measures of action in the ends or things accomplished. (4) There are actions which have a final value apart from their pleasurable character, although also as matter of fact the attainment of ends brings (as *accompaniment* and not as *end*) a feeling of immediate pleasure—e.g. the adaptation of the eye to a pleasing object or healthy muscular exercise in general. Schopenhauer went so far as to say that pleasure is only the absence of pain, pain alone being the positive and preponderating element in a sensitive consciousness. This is simply not true: pleasure—if we take the liberty of talking of pleasure as a thing—is as positive as pain is, and the strife which exists in all life is not necessarily painful.

If we ask the pessimist if there is any freedom or release from the 'bondage of man,' we are answered: (1) The light which the Unconscious Will has kindled for itself in the brain of man (pessimism has of course a pronouncedly naturalistic side) confers on us at least one advantage; employing this light, we may for brief moments pause, and survey with pity the awful slavery and strife of life. In a word, artistic perception, the insight into things of the man of genius, of the emancipated intellect, is freedom: art, asceticism, quietistic sympathy, is each the oasis and salvation in the howling wilderness of life. (2) While individual suicide is to be deprecated as the acme of the selfish assertion of the Will to be happy, it is to be hoped that some day the human race will be educated enough to see the contemptible character of life, and, by a united act of enlightened will, will shake off life and throw the world back into its primeval state of innocence, ignorance, and mere potentiality, and thus become the 'saviour' of the world. There is a basis of moral perception in all this, but it is fantastical: it is the exaggerated statement of the intellectual conditions of salvation often stated in philosophy, as in Aristotle's 'life of contemplation,' the gods of Epicurus, and Spinoza's view of things 'in the light of eternity.' If we demur that it is, then, only the few who can be saved, we are told

that the lot of life is one; my life is the same as that in the plant or the planet, and there is, as matters at present stand, not the least fear that the 'will to live' will die out with the death of my life in quietism, agnosticism, and mysticism.

To the metaphysic of pessimism we may also say: (1) That it is not necessary to have a theory of the world in order to make action possible: no one lives because he chooses to live, but because he must, and this apart from the question whether a theory of life is attainable or already attained. (2) That the value of life cannot be measured altogether by the expectations or equations of the individual as to his own happiness, and that therefore pessimism is overthrown with the rejection of empirical Hedonism or the theory of ethical conduct that makes happiness the end of life. (3) Pessimism has done good in showing up the illusions to which an acceptance of the Hedonistic or the Epicurean ethic leads in theory and practice; it might be held in fact to give a negative account of man's perfection as consisting not in happiness for happiness' sake, but in the pursuit of ends which are absolutely real, apart from man's desire or aversion to them: to the self-seeking self everything is foreign and negative, and also to the perfection-seeking self the ends of appetite and desire are illusory. The various forms of pessimism—the practical, the biological, the sociological, the poetical, are all of value as provisional accounts of the ethical end. The unconditioned sympathy with all forms of life inculcated in modern pessimism is a valuable contribution to ethical theory and history, although of course it is not exactly original to pessimism. (4) The world which Schopenhauer and Hartmann theoretically conceive of is a world which baffles the individual, because in the first instance it appears to them that the world is incomprehensible. Both, in fact, tend to erect our ignorance of the world into a positive principle—the Unconscious; but this is an old metaphysical fallacy. The world which the individual does know—i.e. the small sphere of it he knows—is not a sphere in which he cannot realise himself, but in Kantian language a moral kingdom; it will baffle him if he is only bent on his own happiness. Thus it has been indicated how in a sense the pessimists are not to be held down to an Epicurean theory of morals, although they take their start from that.

BIBLIOGRAPHY.—Schopenhauer's chief work is the *World as Will and Idea* (Eng. trans. 3 vols. 1883-86). His ethic is contained chiefly in the fourth book, on the *Assertion and Denial of the Will to Live*. The appendices contain many exceedingly readable and lucid presentations of the main points of his system, and so do many of the sections of the *Parerya und Paralipomena*, which have a high literary value. See translations of these in Mr T. B. Saunders's 'Schopenhauer' series (1890 *et seq.*). Hartmann's views are expounded in *Philosophy of the Unconscious*, which is also translated into English (1884). An admirable short account of his system for the laic mind is that of Dr A. Drews (*Ed. v. Hartmann's Philosophie*, 1890). E. Wallace's account of pessimism in the *Westminster Review* (1876) is eminently instructive, and has chief reference to Hartmann. An introductory treatise is also that of A. Taubert, *Der Pessimismus und seine Gegner* (1873). Mr Sully's *Pessimism* (1877) is an admirable and careful psychological criticism of pessimism, and contains a good historical sketch. In it there is a list of pessimistic literature. As an introduction to pessimism some account of Leibnitz's philosophy ought to be read, and after it Voltaire's vigorous and drastic criticism of the same in *Candide;* the latter will help one to understand what Schopenhauer meant when he called optimism a 'wicked and otiose shallow philosophy.' The religious aspect of pessimism is touched on in an essay in Seth and Haldane's *Essays in Philosophical Criticism* (1883), and also in Professor Tulloch's *Modern Theories* (1884).

Pestalozzi, JOHANN HEINRICH, educational theorist, was born at Zurich, 12th January 1745. Eccentric, quixotic, eager to be an adjuster of social wrongs from his youth, he sought to realise his aims through educating the young. He shares with Rousseau, whose *Émile* greatly influenced his mind, the honour of conceiving a method which is the corner-stone of all sound theories of primary education. From his day onward two ideas of education co-existed—the older one, applicable to the children of the classes; his, applicable to the children of the masses; the former being in many ways improved by an encroachment of the latter upon its traditional domain. Pestalozzi, living during the period of the French Revolution and the wars of Napoleon, found in his disturbed country, in the misery inflicted by war, opportunity for the display of self-sacrifice, devotion to the oppressed, and that unselfish love of the children of the very poor which especially distinguished him. Illiterate, ill-dressed, a bad speaker, and a bad manager, Pestalozzi was unfit for the everyday business of life, and all his undertakings resulted in practical failure, though rousing the admiration of Europe, and calling forth down to the present day in many countries, more especially in Germany, a crowd of disciples, who have carried out the principles of their master with great enthusiasm. Although he was totally unable to cope with the world, Pestalozzi's personality was instinct with a loving sensibility; he awoke men to a sense of responsibility to childhood, and ushered the 19th century upon the stage of history as the educational age *par excellence*.

His life is soon told. Believing justly in the moralising virtue of agricultural occupations and rural environment, he chose a farm upon which to dwell with his collected waifs and strays as a father among his own. The farm Neuhof, in the canton Aargau, stranded on a faulty domestic economy after a five years' struggle (1780). Pestalozzi withdrew then from practical life, to think out the educational problem. His *Evening Hours of a Hermit* was the first fruit of his meditations, and develops the following thoughts: before undertaking to educate man, learn to know him; the method whereby to educate man should be founded upon his own nature; in his nature are hidden the forces that draw out his faculties, exercise them; exercise, the instrument of education, connects the wants of our nature with the objects that satisfy them; to rejoice in the fullness of your strength, make your education answer to your needs and to the inner call of your soul. Then came a social novel, *Leonard and Gertrude*, in four volumes. The former is a drunken stone-mason, the latter his wife, and a good one; the scene, a village given over to corruption. At last the minister, the schoolmaster, Gertrude with a few peasant-women, set about the reform of the village. This story created much attention, and was followed by a long period of literary activity on the part of its author. In 1798 he plunged into action again by opening his orphan school at Stanz. The picture he there makes of a moneyless, helpless, homeless lover of children, gathering homeless, helpless, children around him in an old convent in a township ruined by war, and set upon by a hostile and ignorant peasantry, is a noble and pathetic picture. But times and men proved too hard for Pestalozzi. At the end of eight months this establishment was broken up.

He next wended his steps to the people's school at Berthoud (Burgdorf), in canton Berne, only to be ejected from his subordinate position there, at the age of fifty-five, by the jealous and bigoted senior master. He knew then the bitterest pangs of poverty, and had even to keep away from church for want of clothes. In partnership with others, and

under the patronage of the Swiss government, he opened an experimental school of his own, still at Berthoud. While there he published *How Gertrude Educates her Children*. Germany greedily devoured the book. It is the recognised exposition of the Pestalozzian method, and sets forth that the development of human nature should be in dependence upon natural laws, with which it is the business of every good education to comply; in order to establish a good teaching method, learn first to understand nature, its general processes in man, and its particular processes in each individual; observation, the result of which is a spontaneous perception (intuition) of things, is the method by which all objects of knowledge are brought home to us. This last affirmation, containing in essence the whole theory of so-called *intuitional* education, is the corner-stone on which the German Volksschule ('folk-school') is built, the guiding principle of numberless books written for children, and the subject of numberless treatises on education.

In 1805 Pestalozzi moved his school to Yverdon, which here drew upon him the eyes of all Europe; in spite, however, of this his greatest moment of popularity and promise of worldly success, he entered upon a course of mistakes that led him to the grave, a disappointed and unsuccessful man. Deviating from the field of primary teaching, he applied his method in a large secondary school for the sons of notable Europeans attracted by his fame. His old incapacity in practical affairs brought the school down step by step till it was closed in 1825, and Pestalozzi, aged eighty, distracted by the enmity of some of his former colleagues, sinking under difficulties of his own making, an object of mingled pity and respect, addressed to mankind the *Song of the Swan*, a last educational prayer, and withdrew to Brugg (Aargau), where he died, 17th February 1827. Pestalozzi's books are all written in German.

See the article 'Pestalozzi' in the last edition of Quick's *Essays* (1890); Morf, *Zur Biographie Pestalozzis* (4 vols. 1864–89); De Guimps' monograph, translated by John Russell (1890); Krüsi's *Pestalozzi* (New York, 1875); *Leonard and Gertrude* (Eng. trans. 1825); and, above all, *Pestalozzi, Étude Biographique* (1890), by J. Guillaume.

Pesth, or more correctly BUDAPEST, because since 1873 it has been united with BUDA (Ger. *Ofen*) into one municipality, is the capital of Hungary, and next after Vienna the second city of the Austrian-Hungarian empire. It stands on the Danube, Buda on the right bank and Pesth on the left, 173 miles by rail SSE. of Vienna. The two towns are connected by three bridges, a chain bridge (designed by Clark Brothers of England in 1842–49), 1280 feet long, uniting the busiest quarters of the two; another, built in 1872–75, a little higher up (1555 feet long); and a railway bridge near the southern end of both towns. Pesth is essentially a modern place, the growth principally of the 19th century; it has many fine streets and squares, the magnificent quays (3 miles long) beside the Danube being the favourite promenades; the buildings are chiefly noteworthy for their substantial appearance and frequently large size. Amongst them may be enumerated the Jewish synagogue (the handsomest place of worship in the city); the parish church (1500) and the new Leopold basilica (1851–68); the national museum (after 1850), containing collections of pictures, ethnography, natural history, mineralogy, botany, numismatics, and plaster-casts, and a library of 400,000 volumes and 63,000 MSS.; the academy of sciences (1862), containing a small collection of valuable old pictures, another of engravings and drawings, and a library of 90,000 volumes; the university (1635), established first at Tyrnau, then at Buda in 1777, and lastly at Pesth in 1873, with 250 lecturers and 4000 students, equipped with excellent scientific laboratories, &c., and a library of 200,000 volumes; the custom-house (1870–74), barracks, military academy (1872), slaughter-house (1870–72), industrial and commercial museums; and the magnificent new parliament houses and the palace of justice, completed for the millennial celebration in 1896.

Whilst Pesth stands on a plain, Buda straggles over small steep hills, and is backed by vine-clad slopes. It is a much older town, its central features being the castle in the citadel (1749–71), with the chapel of St Sigismund, in which are preserved the crown regalia of Hungary and the hand of St Stephen; the church of the Ascension and that of St John (13th century); the palaces of the Honved ministry, the premier, and Archduke Joseph; the monumental tomb of Gul Babas (1543–48), a Turkish saint; and the national lunatic asylum (1860–68).

Both towns are exceptionally well provided with baths, which are supplied both by the Danube and by numerous natural springs of mineral waters. Some of these last—Hunyadi Janos, Rakoczy, &c.—are exported in large quantities in bottles. The artesian well in the public garden of Pesth has been already referred to under ARTESIAN WELL. The water-works of Pesth were planned and built by the English engineer Lindley in 1868. Both towns possess an unusual number of philanthropic institutions, such as hospitals, asylums, &c. There is in Pesth a polytechnic (in Buda, 1846–72), with faculties of chemistry, architecture, and engineering, attended by 620 students, who are taught by 70 lecturers. A great number of learned and scientific societies flourish; and there is a music academy. The people are gay and fond of amusement, especially horseracing and rowing. There are two beautiful public gardens, one in Pesth, the other on Margaret Island in the Danube, just above the town. The squares and streets of both Pesth and Buda are adorned with many statues of celebrated Hungarians. The following figures will show the extraordinarily rapid growth of Budapest: pop. in 1813 was 36,153; in 1833, 63,148; 1857, 116,683; 1869, 270,476; 1881, 370,767; 1891, 491,938. The last summation includes 11,000 military. The figure for 1881 embraced 75,794 in Buda and 294,973 in Pesth; amongst these were close upon 71,000 Jews, mostly living in Pesth. Budapest is the first manufacturing town of Hungary. The making of machinery and agricultural implements, wagons, and ships, the manufacture of spirits, tobacco, beer, gold and silver wares, cutlery, starch, glass, and innumerable other articles, the grinding of corn, washing of wool, and printing are all prosecuted on the large scale; there is here a small-arms factory. But the commerce is even more important: immense quantities of corn are brought into the town, and exported further either as corn or flour; wool, wine and spirits, oil-seeds and agricultural seeds, hemp, tobacco, plums (from Bosnia and Servia), honey and wax, bacon, hides, feathers, timber, coal, and manufactured wares are the principal articles of the extensive trade. Vast numbers of swine are fattened and killed in huge yards just outside Pesth.

The Romans had a military colony on the site of the modern Buda. In the 13th century there existed here a flourishing German town, Old Buda. This was destroyed by the Mongols in 1241; but it soon recovered from the blow. Buda was regarded as the capital of the country from the middle of the same century down to its capture by the Turks in 1527. From 1541 down to 1686 the Turks held Buda, though it was besieged

half-a-dozen times by the Austrians. Pesth meanwhile was reduced to a heap of ruins; and it did not begin to recover until the first quarter of the 18th century. A century later it was rapidly outstripping its twin-sister Buda.

There are German books on Pesth by Hevesi (1873), Körösi (1882), Heksch (1882); and one in Hungarian, by Gerlóczy and Dulácsko (3 vols. 1879).

Pestilence. See Epidemic, Black Death, Cholera, Plague, Sweating Sickness.

Petal. See Flower.

Petard, an instrument for blowing open the gates of a fortress, demolishing palisades, &c., consisting of a half-cone of thick iron filled with powder and ball; this was firmly fastened to a plank, and the latter was provided with hooks to allow of its being attached securely to a gate, &c. The petard, which was lighted by a slow-match, was superseded by the use of powder-bags. Large petards contained as much as 13 lb. of powder. See Bomb, and Shell.

Petavius, Dionysius, the name by which the great Catholic theologian Denys Petau is usually known. Born at Orleans, 21st August 1583, he studied at Orleans and Paris, became a teacher in the university of Bourges in 1602, in 1605 entered the order of Jesuits, and 1621 was made professor of Theology in the university of Paris. This post he held for twenty-two years, but in 1646 he retired and devoted himself to the completion of a remarkable series of works in philology, history, and theology. Of his 49 works among the best known are editions of Synesius (1611) and Epiphanius (1622); *De Doctrina Temporum* (1627); *Tabulæ Chronologicæ* (1628); *Rationarium Temporum*, an outline of universal history (1634); and *De Theologicis Dogmatibus*, a history of doctrines (1644–50; new ed. by Thomas, 8 vols. 1864 *et seq.*); besides polemical works against Grotius and Salmasius. He died in Paris, 11th December 1652.

Petchenegs. See Russia, Vol. IX. p. 43.

Petchora, a large river of Russia, rises on the western slope of the Urals, flows north through the eastern parts of the governments of Vologda and Archangel, then south-east for 150 miles, and finally sweeping northwards into an estuary 30 miles wide and full of islands, falls into the Arctic Ocean, after a course of 975 miles. It is navigable by boats for upwards of 700 miles. The country through which the river flows is thinly peopled and quite uncultivated; dense forests extend on both sides, and the character of the scenery is wild, sombre, and melancholy. See Seebohm's *Siberia in Europe* (1881).

Petechiæ. This term is given to spots of a dusky crimson or purple colour, quite flat, with a well-defined margin, and unaffected by pressure, which closely resemble flea-bites. These spots result from a minute extravasation of blood beneath the cuticle. They occur most frequently on the back, at the bend of the elbow, and in the groin. They indicate an altered state of the blood, and are characteristic of the disease called *purpura;* but are often symptoms of very serious diseases, as of typhus fever, plague, scurvy, &c. They likewise occur in very severe cases of smallpox, measles, and scarlet fever, when their presence must be regarded as indicative of extreme danger.

Peter, St, apostle, named originally Symeon (Acts, xv. 14) or Simon, was 'of Bethsaida' (John, i. 44) on the Lake of Galilee, but during the public ministry of Jesus had his house at Capernaum, which he appears to have shared with his brother Andrew, the household including his mother-in-law and probably children (Mark, ix. 33, 36). His father was called John (John, i. 42; xxi. 15, 16, R.V.) or Jonas (Jonah), and the name by which he himself is known in Christian history is the Greek translation of that given him by Jesus (Cephas, Græcised form of Aramaic *kepha*, meaning 'rock' or 'stone,' Gr. *Petra*, masc. *Petros*). He was a fisherman by occupation, and together with his brother Andrew was actually engaged in the pursuit of his calling on the Sea of Galilee when Jesus called both to be his disciples, promising to make them 'fishers of men.' For this invitation they had been prepared by previous acquaintance, formed perhaps for the first time when they were attending the preaching of John the Baptist (John, i. 40–42), and they both accepted it without hesitation. For the incidents recorded in the life of Peter as a disciple reference must be made to the four canonical gospels. It is plain, especially from the Synoptics, that he was regarded by Jesus with particular favour and affection. In many respects he was indeed an ideal disciple, warmly attached to his master, quick (on occasions at least) to apprehend new ideas, and ardent, energetic, and fearless in following them out. This is seen most clearly at that most important crisis in the life of Jesus when Peter was the first to see and say 'Thou art the Christ, the son of the living God' (Matt. xvi. 16–18); and it is not without reason therefore that Matthew significantly heads his list of the apostles with 'the first, Simon, who is called Peter.' This position of leadership among the twelve Peter continued to hold. In the earliest extant account of the resurrection (1 Cor. xv. 5) it is stated that the risen Christ appeared first 'to Cephas, then to the twelve;' and in the Epistle to the Galatians the apostle Paul tells us that his first errand to Jerusalem after his conversion was 'to visit Cephas' (Gal. i. 18). In the Acts of the Apostles Peter was the first mover in the election of a new apostle in the room of Judas Iscariot; he was the spokesman of the rest on the day of Pentecost, and also when they were brought before the council; he was the judge who condemned Ananias and Sapphira; along with John he was sent from Jerusalem to the Samaritan converts that they might receive the Holy Ghost; and he was the first to baptise a Gentile convert. He took a prominent part in the council or conference at Jerusalem, the result of which, though its events are somewhat differently related in Gal. ii. 1–10 and in Acts, xv. 4–29, was his acceptance of the policy of conciliation between the contending Jewish and Gentile parties. The date of this conference cannot be accurately fixed, but no recent scholar has placed it earlier than 47 A.D. or later than 53 A.D. He afterwards came to Antioch and for a time worked in harmony with Paul, but ultimately the famous dispute arose (Gal. ii. 11–21) which in conjunction with other causes led to the termination of Paul's ministry in that city. Peter, however, seems to have remained in Antioch, and was afterwards regarded as the founder of its church. His subsequent history is very obscure. On any theory of the authorship of 1 Peter that writing bears witness to an early belief that his missionary activity extended as far as to Pontus, Cappadocia, Galatia, Asia, and Bithynia; and, on one interpretation of 1 Peter, v. 13 (which, however, has little probability), he also laboured in Babylon. That he suffered martyrdom is clear from John, xxi. 18, 19, and is confirmed by the unanimous voice of ecclesiastical tradition: as to the manner of it, we have it on the authority of Eusebius (*H.E.* iii. 1, interpreted by some as resting on Origen) that he was impaled or crucified with his head downward; as to the place, tradition from the end of the 2d century invariably mentions Rome, and this also is most probably implied in the vague phraseology of Clemens Romanus (1 *Ep.* v. 4). Another circum-

stance that makes somewhat for a residence, however brief, of Peter in Rome is his probable connection with Mark and the second gospel (see MARK). It may be taken as certain that Peter was not in Rome when the Epistle to the Romans was written, if the 16th chapter of that epistle is to be accepted as genuine; and it is almost equally evident that he cannot have been there when Paul was writing to the Philippians. Thus the comparatively late tradition which assigns him a continuous bishopric of twenty-five years in Rome from 42 A.D. to 67 A.D. must be regarded as unhistorical. If he came at all to Rome it can only have been after 64 A.D. Of the duration of his stay we have no means of judging.

The dispute between Protestants and Catholics as to whether Peter was ever at Rome began as early at least as 1520, when Vehlen (Velenus) published his *Demonstratio contra Romani papæ primatus figmentum;* it was answered by Bishop Fisher of Rochester in his *Convulsio calumniarum Aldrichi Velcni.* For the arguments current in that and the following century, see Spanheim, *Dissertatio de ficta profectione Petri apostoli in urbem Romam* (1679). In later times the question has been the subject of equally acute controversy, but not with the same motives or entirely on the same grounds. The recent discussions began with Baur, who has been followed by Lipsius, Zeller, and others in a complete denial of any historical foundation for the 'Roman Peter-legend;' among those who have sought to vindicate for it some basis of truth may be named Credner, Wieseler, Ewald, Hilgenfeld, and Renan. For the apocryphal *Acts of Peter and Paul*, see Tischendorf. The Greek text of the apocryphal *Gospel according to Peter* and the *Revelation of Peter*, found in 1886-87 at Akhmim in Egypt, was published in 1892 by J. A. Robinson and M. R. James, and by others. For those of the *Preaching of Peter*, his *Journeys*, &c., see also Hilgenfeld. And see Littledale's *Petrine Claims* (1889). Lightfoot's *Apostolic Fathers*, part i. (2d ed. 1890); on the Catholic side, Allies, *The See of St Peter* (1850) and *St Peter* (2d ed. 1871); Döllinger's *First Age of the Church* (3d Eng. ed. 1877); and Johann Schmid, *Petrus in Rom*, where the literature on both sides of the question is very fully given. On the whole subject of the history and legends connected with the name of Peter the important work of Lipsius, *Die apokryphen Apostelgeschichten und Apostellegenden* (1883-90), ought to be consulted.

Peter, THE EPISTLES OF, constitute two of the seven canonical writings of the New Testament which towards the beginning of the 3d century began to be spoken of as 'catholic' epistles. Eusebius (*H.E.* iii. 3) tells us that 'as to the writings of Peter, one of his epistles called the first is acknowledged as genuine. For this was anciently used by the fathers in their writings as an undoubted work of the apostle. But that which is called the second we have not indeed understood to be embodied with the sacred books, yet, as it appeared useful to many, it was studiously read with the other scriptures.' Among the earliest witnesses to the antiquity of the first epistle the first usually cited is Clemens Romanus, who is supposed to be quoting from it when he uses the phrases 'his marvellous light' and 'charity covereth a multitude of sins.' It was known to the author of *The Shepherd of Hermas*, and to Basilides; Papias was acquainted with it; and Polycarp used it largely; but it is not mentioned as canonical in the Muratorian Canon. Coming to the internal evidence, it claims to have been written by the apostle Peter, by the hand of Silvanus, from 'Babylon' to 'the elect who are sojourners of the Dispersion in Pontus, Galatia, Cappadocia, Asia, and Bithynia,' and in substance it is a practical exhortation to a godly conversation, particularly in obedience to all constituted authorities, in the practice of the domestic virtues and in patience under persecution. The 'elders' are exhorted to feed their flocks, the 'younger' to obey, and all to be sober, watchful and constant in the faith, resisting their adversary the devil. Throughout it abounds with echoes of Pauline expressions and modes of thought; in particular the exhortations contained in Rom. xii. 1-xiii. 14 have been reproduced virtually verse by verse. This circumstance of its dependence on the Pauline writings is one of the main arguments with those critics (such as Baur, Schwegler, Keim, Lipsius, Pfleiderer, Weizsäcker, Hilgenfeld, Holtzmann) who fix its date at some period after 112 A.D. in the reign of Trajan, by whom formal proceedings were first instituted against Christians. They find confirmation of their view in the use of the name 'Babylon' for 'Rome;' a use that seems to have been first introduced by the author of the Apocalypse. The second epistle claims to be by 'Symeon Peter' (i. 1), the associate of Paul (iii. 15), and a witness of the resurrection (i. 17, 18); the expression 'your apostles' (iii. 2, R.V.), on the other hand, is held by many critics to be a confession of the author's non-apostolicity. The evidence supplied by itself as to its authorship has been variously interpreted, some affirming and some denying that its thought, expression, and vocabulary conclusively show that it cannot have been written by the author of 1 Peter. Its relation to the Epistle of Jude is also still under discussion, but the weight of opinion seems to be in favour of the priority of the latter. The external evidence as to its existence down to the end of the 2d century is very uncertain; and Origen is quoted by Eusebius as saying that even in his day 'there was some doubt' as to whether it was by Peter.

The genuineness of both epistles is argued for (to mention only two out of many weighty names) by Salmon (*Introduction to the New Testament*) and by Weiss (*Einleitung;* Eng. trans. 1888); the opposite view is taken by Holtzmann (*Einleitung*, 1886), who may be consulted for references to other authors, many of whom accept the first epistle while rejecting the second. There are commentaries on both by Fronmüller (in Lange's *Bibelwerk*), Huther (in Meyer's *Kommentar;* Eng. trans.), Lillie, and Plumptre. Leighton's *Practical Commentary* on 1 Peter is one of the classics of English theology.

Peter the Cruel. See PEDRO.

Peter the Great. Peter I., Alexandreievich, emperor of Russia, was the son of the Czar Alexei by his second wife, Natalia Narishkina, and was born at Moscow, 11th June 1672. His father died in 1676, leaving the throne to his eldest son, Feodor, Peter's half-brother. This prince, however, died in 1682 without issue, after naming Peter as his successor, to the exclusion of his own full brother, Ivan, who was weak-minded. This step immediately provoked an insurrection of the 'streltzi' or militia, fomented by Ivan's sister, the grand-duchess Sophia, who, after a carnage of three days, succeeded in obtaining the coronation (July 1682) of Ivan and Peter as joint rulers, and her own appointment as regent. Up to Peter's coronation his education had been greatly neglected, but after this time he had the good fortune to fall under the guidance of Lefort (q.v.), a Genevese, who initiated him into the sciences and the arts of civilisation, and by showing him how much Muscovy was in these respects behind the rest of Europe, influenced the whole of his future career. Lefort also formed a small military company out of the young men of noble family who attended Peter, and he rendered the czar himself all the while amenable to strict discipline. This course of training in all probability saved Peter from becoming the mere savage despot which his brutal and passionate disposition and indomitable energy inclined him to be; it also protected him from the jealousy of his half-sister, the regent Sophia, who thought him absorbed in military exercises, studies, and amusements. She, however, soon discovered her error, for Peter, contrary to her wishes, married (1689), by his mother's advice, Eudoxia Feodorovna

Lopukhin; and in October of the same year called upon his sister to resign the government. In the ensuing contest Peter was at first worsted, and compelled to flee for his life; but he was joined by the foreigners in the Russian service, with Patrick Gordon (q.v.) and Lefort at their head; and the streltzi flocking to his standard, Sophia resigned the contest, and was shut up in a convent, whence, till her death in 1704, she did not cease to annoy him by her intrigues. On October 11, 1689, Peter made his public entry into Moscow, where he was met by Ivan, to whom he gave the nominal supremacy and precedence, reserving the sole exercise of power for himself. Ivan only enjoyed his puppet sovereignty till 1696.

Peter's first care on assuming the government was to form an army disciplined according to European tactics, in which labour he was greatly aided by Gordon and Lefort, both of whom were military men. He also laboured to create a navy, both armed and mercantile; but at this period Russia presented few facilities for such an attempt, for she was shut out from the Baltic by Sweden and Poland (the former of whom possessed Finland, Ingria, and the Baltic provinces), and from the Black Sea by Turkey, leaving only the White Sea and the Arctic Ocean, with the solitary port of Archangel, available for the Russian navy. Peter, thinking the possession of a portion of the Black Sea would best supply the required facilities of accessible seaboard and port, declared war against Turkey, and took (1696) the city of Azov at the mouth of the Don, after a long siege. Skilled engineers, architects, and artillerymen were now invited from Austria, Venice, Prussia, and Holland; ships were constructed, and the army further improved both in arms and discipline. Many of the young nobility were ordered to travel in foreign countries, chiefly in Holland and Italy, and to take special notice of all matters in connection with shipbuilding and naval equipments; others were sent to Germany to study the military art. Peter was eager to see for himself the countries for which civilisation had done so much; and, after repressing a revolt of the streltzi and dispersing them among the various provinces, he left Russia in April 1697, in the train of an embassy of which Lefort was the head. In the guise of an inferior official of the embassy he visited the three Baltic provinces, Prussia, and Hanover, reaching Amsterdam, where, and subsequently at Zaandam, he worked for some time as a common shipwright; and to his practice of shipbuilding and kindred trades he added the study of astronomy, natural philosophy, geography, and even anatomy and surgery. On receipt of an invitation from William III. he visited England, and for three months, spent partly in London and partly at Deptford, laboured to amass all sorts of useful information. While in England he received the honorary degree of D.C.L. from the university of Oxford. He left England in April 1698, carrying with him English engineers, artificers, surgeons, artisans, artillerymen, &c., to the number of 500, and next visited Vienna, for the purpose of inspecting the emperor of Austria's army, then the best in Europe. He was about to visit Venice also, when the news of a formidable rebellion of the streltzi recalled him to Russia. General Gordon had already crushed the revolt, and Peter finally broke up the institution that had given him so much trouble. The Empress Eudoxia, who was suspected of complicity in the conspiracy, which had been the work of the old Russian or anti-reform party, was divorced and shut up in a convent, and the great reforms were begun. Peter put the press on a proper footing, caused translations of the most celebrated works of foreign authors to be made and published, and established naval and other schools. Ordinary arithmetic was first introduced, accounts having been previously kept by means of the Abacus (q.v.). Trade with foreign countries, which was formerly punished as a capital crime, was now permitted, or rather, in the case of the principal merchants, insisted upon. Many changes in dress, manners, and etiquette were introduced and enforced on the people at large. Even the organisation of the national church could not escape Peter's reforming zeal.

In 1700 Peter, desirous of gaining possession of Carelia and Ingria, provinces of Sweden which had formerly belonged to Russia, entered into an alliance with the kings of Poland and Denmark to make a combined attack on Sweden; but he was shamefully defeated at Narva, his raw troops being wholly unable to cope with the Swedish veterans. Peter was by no means disheartened, but quietly appropriated a portion of Ingria, in which he laid the foundation of the new capital, St Petersburg, 27th May 1703. Great inducements were held out to those who would reside in it, and in a few years it became the Russian commercial depôt for the Baltic. In the long contest with Sweden the Russians were almost always defeated; but Peter saw that these reverses were administering to his troops a more lasting and effective discipline than he could have hoped to give them in any other way. He had his revenge at last, in totally routing the Swedish king, Charles XII., at Pultowa (q.v.), 8th July 1709, and in seizing the whole of the Baltic provinces and a portion of Finland in the following year. His success against Sweden helped much to consolidate his empire and to render his subjects more favourably disposed towards the new order of things. After reorganising his army he prepared for strife with the Turks, who, at the instigation of Charles XII. (then residing at Bender), had declared war against him (see TURKEY). In this contest Peter was reduced to such straits that he despaired of escape. But, according to a somewhat doubtful tradition, the finesse and ability of his mistress, Catharine, extricated him from his difficulties; and a treaty was concluded (1711) by which Peter lost only his previous conquest—the port of Azov and the territory belonging to it. He was thus shut out from the Black Sea, so the possession of a good seaboard on the Baltic became the more necessary to him, and the war against Sweden in Pomerania was accordingly pushed on with the utmost vigour. In 1712 his marriage with his mistress, Catharine (see CATHARINE I.), was celebrated at St Petersburg, and the offices of the central government were transferred to the new capital. His arms in Pomerania and Finland were victorious, and in 1713 the latter province was completely subdued. In 1716–17, in company with the czarina, he made another tour of Europe, this time visiting Paris, and returned to Russia in October 1717, carrying with him quantities of books, paintings, statues, &c. It was soon after this time that his son Alexei (q.v.), who had opposed some of his father's reforms, was condemned to death, and died in prison—apparently through having been repeatedly tortured. Many of the nobles who had been implicated in his treasonable plans were punished with savage barbarity. In 1721 peace was made with Sweden, which definitely ceded the Baltic provinces, Ingria (now government of St Petersburg), and a portion of Finland, with the islands off the coasts. In 1722 Peter commenced a war with Persia, in order to open up the Caspian Sea to Russian commerce, and secured three Caspian provinces along with the towns of Derbend and Baku. For

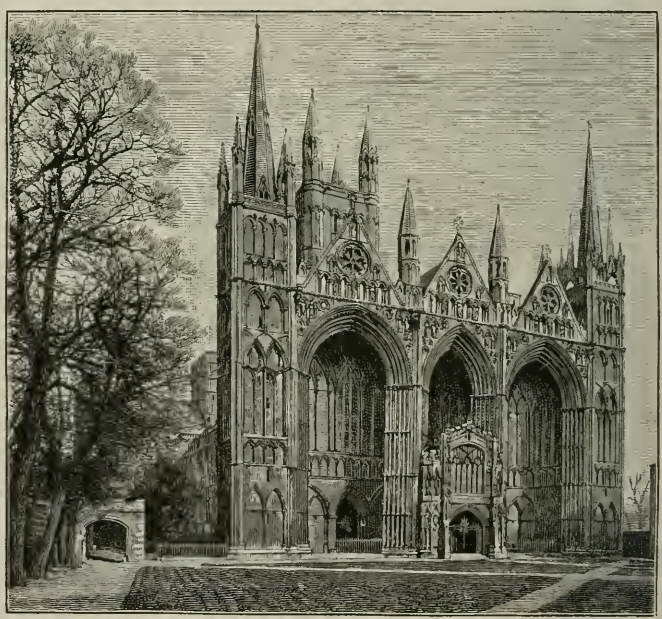
the last years of his life he was chiefly engaged in beautifying and improving his new capital and carrying out plans for the more general diffusion of knowledge and education among his subjects. In the autumn of 1724 he was seized with a serious illness, and he died 8th February (28th January o.s.) 1725. Catharine succeeded him. The 'Testament of Peter the Great,' inciting the Russians to aim at domination in Europe, is a forgery, based probably on Lesur's *Progrès de la Puissance Russe* (1807), and, it may be, inspired by Napoleon.

See Russian Lives by Golikov (30 vols. 1797) and Ustraljov (1863); English Lives by Barrow (new ed. 1883) and Schuyler (2 vols. 1884); and for a vindication of the authenticity of the 'Testament,' W. J. Thoms in the *Nineteenth Century* (1878).

Peter II. (Alexeievich) of Russia, was the sole male representative of Peter the Great, being the son of the unfortunate Alexei (see above), and was born 23d October 1715 at St Petersburg. On the death of the Czarina Catharine I. he ascended the throne (1727). Menschikoff, his guardian, affianced one of his daughters to the youthful czar, but his power was overturned by the Dolgoronki family; and the czar was seized with smallpox, and died at St Petersburg, January 29, 1730.

Peter III. (Feodorovich) of Russia, grandson of Peter the Great (being the son of his eldest daughter Anna Petrowna, wife of the Duke of Holstein-Gottorp), was born at Kiel, 29th January 1728, and in 1742 was declared by the Czarina Elizabeth (q.v.) her successor on the throne of Russia. From the time of his being publicly proclaimed heir he lived at the Russian court; and in obedience to the wishes of the czarina he married Sophia-Augusta, a princess of Anhalt-Zerbst, who on entering the Greek Church assumed the name of Catharina Alexeievna. Peter succeeded Elizabeth on her death in 1762; and his first act of authority was to restore East Prussia to Frederick the Great (whom he admired extravagantly), and to send to his aid a force of 15,000 men. He also recalled many of the political exiles from Siberia. When arranging in 1762 a campaign to take Sleswick from Denmark a formidable conspiracy, headed by his wife, and supported by the principal nobles, broke out against him—a conspiracy which originated in the general discontent at the czar's liberal innovations, the preference he showed for Germans, his indifference to the national religion, and his servility to Frederick the Great. The czar was declared to have forfeited his crown; his wife Catharine was proclaimed as Catharine II. (q.v.); and Peter, who supinely abdicated, was strangled by Orloff and some of the conspirators on the 17th July 1762.

Peterborough, a city partly in Huntingdonshire, but chiefly in Northamptonshire, the latter portion being on the left or north bank of the river Nen, at the edge of the fen-country, 76 miles N. of London and 42 NE. of Northampton. Here, at Medeshamstede, in 655, the Mercian thane Saxulf founded the great Benedictine abbey of SS. Peter, Paul, and Andrew, which, destroyed by the Danes in 870, was restored in 966, plundered by Hereward in 1069, and again burned down in 1116. Its noble church, the cathedral since 1541 of a new diocese carved out of that of Lincoln, was built between 1118 and 1528, and thus, whilst essentially Norman, offers every variety of architecture down to the Perpendicular. It is 471 feet long, by 202 across the transept, and 81 high. The Early English west front (*c.* 1200–22) consists of three mighty arches, and 'is perhaps,' says Freeman, 'the grandest conception for a single feature which mediæval architecture has produced, a Greek portico translated into Gothic language.' Noteworthy also are the flat painted wooden ceilings of the 12th century, the portrait of 'Old Scarlett' the sexton (1496–1594), the blue slab inscribed 'Queen Catharine, A.D. 1536,' and the grave for twenty-five years (1587–1612) of Mary Queen of Scots. In 1643 Cromwell and his troopers did hideous havoc to monuments, stained glass, and cloisters. In 1883 the fine central tower was condemned as unsafe; but it has been lovingly rebuilt, and in 1890 the cathedral was reopened after restoration. Of the abbots may be mentioned Ernulf, Bishop of Rochester (1115); and of the twenty-seven bishops, Lloyd and White the non-jurors, Richard Cumberland, Archbishop Magee of York, and Mandell Creighton the historian. Paley was a native. Two ancient gateways, the bishop's palace and the deanery (once the abbot's and prior's houses), and the chancel of a Becket chapel (now a museum) make up the remaining objects of interest. A training-college for schoolmasters (1864), a grammar-school, the town-hall (1671), the corn exchange (1848), a cattle-market of five acres (1867), and the bridge over the Nen (dating from 1140, but in its present form from only 1872) may be mentioned. Peterborough is an important railway centre, has manufactures of agricultural implements, and carries on a large trade in malt, coal, farm-produce, &c. Incorporated as a municipal borough in 1874, it has returned two members to parliament from 1547 till 1885, and since then one. Pop. (1841) 6959; (1881) 22,394; (1891) 25,172.



Peterborough Cathedral—West Front.

See works by Gunton (1686; new ed. 1825), Britton (1828), F. A. Paley (1849), Davys (3d ed. 1863), Sweeting (1869), and Poole (1881).

Peterborough, chief town of Peterborough county, Ontario, on the Otanabee River (here crossed by six bridges), 82 miles by rail NE. of Toronto. It exports lumber and agricultural products, and manufactures flour, woollens, farming implements, machinery, furniture, canoes, &c. Pop. 8500.

Peterborough, CHARLES MORDAUNT, EARL OF, was born in or about the year 1658. All particulars of his boyhood, even to the place of his education, seem to have been lost. The first definitely recorded event in his life is his voyage as a volunteer in Sir John Narborough's expedition against the Algerine corsairs in 1674. From this voyage, in which he saw actual service, he returned early in 1677, to find himself in his twentieth year Viscount Mordaunt, his father, John, first peer of that title, which he owed to his services in assisting to bring about the Restoration, having died in 1675. The new viscount shortly afterwards married Carey, daughter of Sir Alexander Fraser, and in 1678 started on another maritime expedition, this time apparently in the capacity of a passenger. Returning after a year's absence, he again volunteered for naval service, and sailed with the fleet sent under Lord Plymouth for the relief of Tangier. On his return to England he began to take an active part in politics, identifying himself with the extreme Whig party throughout the whole of the three or four eventful years which closed with the ruin and flight of Shaftesbury, and the final triumph of the indolent and dissolute but shrewd and able monarch, against whom that restless agitator had pitted himself. At the accession of James II. Mordaunt became a prominent parliamentary opponent of the first unpopular measures of the new king, and one of the earliest intriguers for his overthrow. Indeed he went at once so fast and so far as to press upon William of Orange a premature scheme for the invasion of England, which that prince with his usual cool judgment rejected. After the Revolution, in the military operations connected with which Mordaunt exerted himself vigorously and with success, he rose into high favour with the new king. Honour and emoluments of a varied description, from the post of a privy-councillor to that of a water-bailiff, were heaped upon him, and he was finally appointed First Commissioner of the Treasury, and created Earl of Monmouth. On William's departure for the campaign in Ireland the new earl was nominated of the committee of nine who formed the Queen's Council of Regency. In the House of Lords he was an extreme and active Whig, but it was probably as much his zealous anxiety to supplant William's ministers suspected of Jacobitism as to combat Jacobite designs themselves that led to his embroilment in those intrigues arising out of the Assassination Plot, and the Fenwick trial, which ultimately resulted (January 1697) in his committal to the Tower. He was liberated in less than three months, and for several years thereafter he seems to have played no prominent part in public affairs.

In 1702 the war of the Spanish succession broke out, and in 1705 Peterborough (for by his uncle's death he had succeeded to that title shortly after his release from imprisonment) was appointed to the command of an army of 4000 Dutch and English soldiers, with which he proceeded to Barcelona, there to begin the extraordinary campaign which has made his name famous in history. After successfully resisting the solicitations to attack the city which were addressed to him by the Prince of Hesse-Darmstadt, fresh from the capture of Gibraltar, and the Archduke Charles, the claimant to the Spanish throne, for whom the allies were fighting, Peterborough succeeded by a pretended retreat in surprising and capturing the strong fort of Monjuich on the south side of Barcelona, from which position of vantage he soon managed to reduce the city. The Catalan towns one after another now declared for Charles; Gerona, Tarragona, Tolosa, and Lerida opened their gates to Peterborough, who, marching southward in the depth of winter and driving his foes before him, reached Valencia early in February 1706. Meanwhile an army under the Duke of Anjou, the French claimant to the throne (afterwards Philip IV.), and Marshal Tessé had entered Catalonia, and was closely investing Barcelona, which was at the same time blockaded by a fleet under the Count of Toulouse. Hurrying back to the scene of his former exploit, and seeing that it was from the side of the sea that the town must be relieved, Peterborough threw himself on board one of the ships of the English squadron, took command in virtue of his commission, which gave him supreme control over the British forces at sea as well as on land, sent his orders to the admiral, and drove Toulouse and his fleet from before the port. This success was followed by the raising of the siege, and the retreat of Tessé's force. Encouraged by the splendid successes of Peterborough on the east coast, Galway, the British commander on the Portuguese frontier, advanced into the heart of Spain, and in June entered Madrid. Peterborough wished to march from Valencia, whither he had now returned, and to effect a junction with Galway, but the archduke dallied irresolutely at Barcelona. Precious time was lost, Berwick rallied his forces, and compelled Galway to evacuate the capital, and when at last Charles advanced and summoned Peterborough to join him, it was too late. A plan formed by him for the recovery of Madrid was rejected, and in disgust he obtained permission to depart for Genoa to raise a loan on the Spanish revenues. Returning with success from his mission, he acted for some time as a sort of adviser to his military successors in Spain, but his imperious temper seems to have unfitted him for anything but supreme command, and his differences with Lord Stanhope and others led to his recall in March 1707.

His career thenceforward till his death at Lisbon on 25th October 1735 is interesting only to the student of letters and not to the politician. He was, as is well known, an intimate friend of Pope, with whom he was in constant communication almost up to the last day of his life, and whose genuine esteem for him may satisfy us that under the somewhat theatrical exterior which he presented to the world there lay qualities which justly endeared him to his friends. In 1722 he was, it is said, privately married to the famous singer Anastasia Robinson, but the lady was not publicly acknowledged as his countess till shortly before his death. Recent military criticism has made an elaborate endeavour to show that Peterborough's fame as a conqueror rests wholly on a basis of imposture, and that the whole credit of his conquest of Valencia must be distributed among others. This extreme view, however, has been shown by Mr Stebbing in his judicious and impartial monograph to be untenable. His verdict is that 'the figure of the hero remains much where it was, though its pedestal may have been somewhat lowered.'

See the Memoir by Russell (2 vols. 1887), and Stebbing's *Peterborough* ('English Men of Action' series, 1890).

Peterhead, a seaport and burgh of barony of Buchan, Aberdeenshire, on a peninsula, 32 miles by road, but 44 by a branch-line (1862), NNE. of Aberdeen. Founded in 1593, it is somewhat irregular in plan, but clean and largely built of the celebrated 'Peterhead granite,' whose reddish

variety is so much used for monumental purposes. The Keiths, Earls Marischal, were superiors of the place till the rebellion of 1715, when the Old Pretender landed here, and after which their forfeited estates were purchased by the Edinburgh Merchant Maiden Hospital, to whose governors many improvements are owing. Of Marshal Keith (q.v.) a bronze statue was presented to the town in 1869 by King William of Prussia; and the market-cross, a granite Tuscan pillar (1833), bears the arms of the Earls Marischal. The public buildings include the town-hall (1788), with a spire 125 feet high; the parish church (1803), with one of 118 feet; the free library and museum (1891); the academy (1846); and convict-prison (1889). Industries are woollen manufactnre, boat-building, and granite-polishing. Peterhead was made a head-port in 1838. From 1788 it gradually became the chief British seat of the seal and whale fisheries, until in 1852 it sent out 30 ships; but since then there has been a great decline. At present Peterhead is chiefly important for its great herring-fishery, which employs upwards of 500 boats, and which during the herring season brings some 5000 persons to the place. The south harbour was commenced in 1773, and the north harbour in 1818, a canal being formed between them in 1850; whilst a new harbour was formed and the south harbour deepened under Acts of 1873 and 1876. Their three basins, hewn out of the solid rock, together cover about 22 acres, and have cost £300,000; but all three are as nothing compared with the great harbour of refuge, the works for which, designed by Sir John Coode, were commenced in 1886, and are to be completed in 1921 at a cost of £746,000. In the neighbourhood are the ruins of Inverugie, Ravenscraig, and Boddam castles, all strongholds of different branches of the Keiths; Buchan Ness, the most easterly point of Scotland, with a lighthouse (1827); and the Bullers of Buchan (q.v.). Since 1833 Peterhead has united with Elgin, &c. to return one member to parliament. Pop. (1801) 3264; (1851) 7298; (1881) 10,922; (1891) 12,226.

See Peter Buchan's *Annals of Peterhead* (1819), besides works by W. Laing (1793) and Arbuthnot (1815).

Peterhof, a palace of the emperor of Russia, on the southern shore of the Gulf of Finland, 18 miles W. of St Petersburg, was built by Peter the Great in 1711, contains a fine collection of paintings, and is surrounded by beautiful parks and gardens laid out on the model of those at Versailles, with cascades, terraces, and summer-houses. The town of Peterhof has 14,298 inhabitants.

Peter Lombard. See LOMBARD.

Peterloo Massacre, the name popularly given to the dispersal of a large meeting by armed force in St Peter's Field, Manchester, Monday, August 16, 1819. The assemblage, consisting chiefly of bodies of operatives from different parts of Lancashire, was called to consider the question of parliamentary reform, and the chair, on open hustings, was occupied by 'Orator' Hunt (q.v.). The dispersal took place by order of the magistrates; several troops of horse, including the Manchester Yeomanry, being concerned in the affair. Eleven persons (men, women, and children) were killed, and some 600 wounded. St Peter's Field is now the site of the Free-trade Hall. 'Peterloo' was a name suggested by Waterloo.

Peter Martyr, the patron saint of the Inquisition, a Dominican of Verona, who, for the severity with which he exercised his inquisitorial functions, was in 1252 slain at Como by the infuriated populace. His death formed the subject of a masterpiece by Titian, destroyed by fire at Venice in 1867.

Peter Martyr (Ital. *Pietro Martire Vermigli*), Reformer, was born in Florence, September 8, 1500, entered at sixteen the order of the canons regular of St Augustine at Fiesole, studied at Padua, and became abbot of Spoleto, and later prior of St Peter ad Aram near Naples. Here he was drawn into the doctrines of the Reformers by the teaching of Juan Valdes and Ochino, yet was appointed visitor-general of his order in 1541. His rigour made him hateful to the dissolute monks, and he was sent to Lucca as prior of San Frediano, but soon fell under the suspicions of the Inquisition, and had to flee to Zurich (1542). At Strasburg he was welcomed by Bucer, and made professor of the Old Testament. In 1547 he came to England on Cranmer's invitation, lectured at Oxford on 1 Corinthians and Romans, and took an active part in the great controversy of the day. Mary's accession drove him back to Strasburg, now grown too Lutheran for his tastes, and at length in 1555 he repaired to Zurich, where he died, November 12, 1562. His admirable *Loci Communes* was printed at London in 1575. See the study by C. Schmidt (Elberfeld, 1858).

Peter Martyr Anglerius, historian, was born in 1459 at Arona, on the Lago Maggiore, of an ancient family belonging to Anghera, obtained a footing at the court of Ferdinand and Isabella in 1487, and rose to high ecclesiastical preferment in Spain. He was ultimately named Bishop of Jamaica, and died at Granada in 1525. He wrote *De Orbe Novo* (1516), giving the first account of the discovery of America; *De Legatione Babylonica* (1516); and *Opus Epistolarum* (1530). See Bernays, *Petrus Martyr Anglerius und sein Opus Epistolarum* (1890).

Petersburg, the third city of Virginia, on the south bank of the Appomattox River, 23 miles by rail S. of Richmond. The falls above supply water-power for foundries, cotton, flour, and paper mills, and especially tobacco-factories. Petersburg is a well-built place, and contains a fine park. In the campaign of 1864 Grant, failing to take Richmond, besieged Petersburg, and was repulsed in several attacks by General Beauregard, with heavy loss. Pop. (1890) 22,680.

Petersburg. See ST PETERSBURG.

Petersfield, a market-town of Hampshire, 20 miles NNE. of Portsmouth by rail. Till 1832 it returned two members, and then till 1885 one. Pop. 1646.

Peter's-pence (*denarius S. Petri*), the name given to a tribute offered to the Roman pontiff in reverence of the memory of St Peter. From an early period the Roman see had been richly endowed; but the first idea of an annual tribute came from Anglo-Saxon England. It is ascribed by some to Ina (721 A.D.), king of Wessex, by others to Offa of Mercia, and by Lingard to Alfred the Great. It was extended to Ireland by Henry II. The tribute consisted in the payment of a silver penny by every family possessing land or cattle of the yearly value of 30 pence, and it was collected during the five weeks between St Peter's and St Paul's Day and August 1. The tax, also called Rome-scot, varied greatly in amount, but continued to be paid with intervals till the reign of Henry VIII. By Gregory VII. it was sought to establish it for France; and traces of a similar payment appear also in Denmark, Sweden, Norway, and Poland. This tribute differed from the payments of the feudatory kingdoms, such as Naples, Aragon, and England under the reign of John. The tribute practically ceased at the Reformation. The pope having suffered a considerable diminution of his own revenue since the revolution of 1848, an effort was made in several parts of Europe to revive the

payment of Peter's-pence, not as a tribute but by the collection of free-will offerings. In some countries it has been very successful; and since the total annexation of the Papal States to the kingdom of Italy the tribute has been largely increased in France, Belgium, England, and Ireland. In 1877, on occasion of the jubilee of Pius IX., the payment amounted to £660,000.

Peter the Hermit, the apostle of the first crusade, was of gentle birth, and a native of Amiens, where he was born about the middle of the 11th century. He served some time as a soldier, became a monk, and is usually said to have made a pilgrimage to the Holy Land before 1094, when he began the preaching campaign which was to render him famous, and leave such a mark on history. But it should be noted that Hagenmeyer in his monograph *Peter der Eremita* (1880) denies that Peter was ever in Palestine till he went with the crusaders, and asserts that the scheme of a crusade originated with the pope, not with the hermit. The article CRUSADES gives an account of his preaching, its results, and of poor Peter's faint-hearted attempt at desertion during the siege of Antioch. After the end of the crusade he returned to Europe, and founded a monastery at Huy in the Low Countries, where he died, 7th July 1115. His remains were translated to Rome in 1634.

Peter the Wild Boy was found in July 1724 in a wood near Hameln in Hanover; 'he was walking on his hands and feet, climbing up trees like a squirrel, and feeding upon grass and moss of trees.' He was taken to George I., brought over by him to England in 1726, and placed under the care of the celebrated Dr Arbuthnot, who had him baptised 'Peter.' He was fond of music, but could never be taught to articulate more than 'Ki Sho,' 'Qui Ca,' and 'Hom Hen,' for 'King George,' 'Queen Caroline,' and 'Tom Fen'—the last a Hertfordshire farmer with whom he lived after 1737. He would sometimes ramble away, on one occasion as far as Norwich, so was provided with a brass collar inscribed 'Peter the Wild Boy, Broadway Farm, Berkhampstead.' Lord Monboddo visited him in 1782, and in his *Origin of Language* describes him as only 5 feet 3 inches high, now about seventy years of age, quite tame, bearded, and fresh and healthy. But on the farmer's death Peter took to his bed, refused food, and in a few days died, in August 1785. See *Notes and Queries* for 11th October 1884, and works there cited.

Peterwardein, one of the strongest fortresses in the Austrian dominions, is situated in a marshy, unhealthy locality on the right bank of the Danube, 44 miles by rail NW. of Belgrade, and is connected with Neusatz opposite by a bridge of boats. Pop. of town, 3603. The most ancient part of the defences, the Upper Fortress, is situated on a rock of serpentine, which on three sides rises abruptly from the plain. The fortress was held by the Turks from 1526 to 1687. In 1688 the fortifications were blown up by the imperialists, and the town was soon after burned to the ground by the Turks; but at the peace of Passarowitz (1718) it remained in the possession of the emperor. Here, on 10th August 1716, Prince Eugene obtained a great victory over the Grand Vizier Ali. The Hungarians were compelled to yield the fortress to the Austrians in September 1849.

Petiole. See LEAF.

Pétion de Villeneuve, JÉRÔME, a prominent figure in the French Revolution, was the son of a *procureur* at Chartres, and was born there in 1753. He was practising as an advocate in his native city when he was elected in 1789 its deputy to the *Tiers État*. An ardent republican and fluent speaker, he quickly became popular, although essentially windy, verbose, and of mediocre understanding. He was a prominent member of the Jacobin Club, and as 'Pétion the Virtuous' became a great ally of 'Robespierre the Incorruptible.' He was sent along with Barnave and Latour-Maubourg to bring back the fugitive royal family from Varennes, and in the execution of this commission he acted in a brutal and unfeeling manner. He afterwards advocated the deposition of the king, and the appointment of a popularly elected regency, and along with Robespierre received, 30th September 1791, the honours of a civic crown. On the 14th of November he was elected mayor of Paris in Bailly's stead, the court favouring his election to prevent that of Lafayette. The invasion of the Tuileries by the mob and the atrocious September massacres both fell within his year of office. He became the first president of the Convention, and was made ridiculous as 'roi Pétion' through Manuel's proposal to give the president the same authority as the president of the United States. On the triumph of the Terrorists Pétion's popularity declined, and he cast in his lot more and more with the Girondists, having become a *habitué* of Madame Roland's *salon*. Like them he voted at the king's trial for death, but with delay of execution and appeal to the people. He was elected to the first committee of general defence in March 1793, and on 12th April he headed the fatal because unsuccessful attack on Robespierre. Proscribed among the twenty-two, on the 2d of June, he escaped to Caen, and on the failure of the attempt to make armed opposition against the Convention fled to the Gironde with Guadet, Buzot, Barbaroux, Salle, and Louvet, and hid in a grotto at St Émilion. At length they were tracked and obliged to flee. The bodies of Pétion and Buzot were found in a cornfield, partly devoured by wolves. They were supposed to have died by their own hands.

His *Œuvres* fill 3 vols. (1792). See J. J. Regnault-Warin's hyper-eulogistic life (1792); C. A. Dauban's *Mémoires inédits* (1866); and C. Vatel's *Charlotte Corday et les Girondins* (3 vols. 1872).

Petition, a supplication preferred to one capable of granting it. The right of the British subject to petition the sovereign or either House of Parliament for the redress of grievances is a fundamental principle of the British constitution, and has been exercised from very early times. The earliest petitions were generally for the redress of private wrongs, and the mode of trying them was judicial rather than legislative. The earlier petitions were generally addressed to the House of Lords; the practice of petitioning the House of Commons first became frequent in the reign of Henry IV. Since the Revolution of 1688 the practice has been gradually introduced of petitioning parliament, not so much for the redress of specific grievances, as regarding general questions of public policy. Petitions must be in proper form and respectful in language; and there are cases where petitions to the House of Commons will only be received if recommended by the crown, as where an advance of public money, the relinquishment of debts due to the crown, or compensation for losses out of the public funds is prayed for. A petition must, in ordinary cases, be presented by a member of the House to which it is addressed. The system is, however, not without its disadvantages, as when the attempt is made to over-ride the courts of law by popular agitation—vast numbers of petitions being presented on behalf of murderers convicted after fair trial. For election petitions, see PARLIAMENT, Vol. VII. p. 775. The monster Chartist petition of 1848 claimed to bear six million signatures. In the five years ending 1842 the number of petitions presented to the House of Commons was 70,072; in the five years ending 1872, 101,573;

in the years 1873–81, 123,870. In one year (1875) there were as many as 20,610, signed by 3,088,970 persons. On the other hand, the year 1889 produced only 8317 petitions.

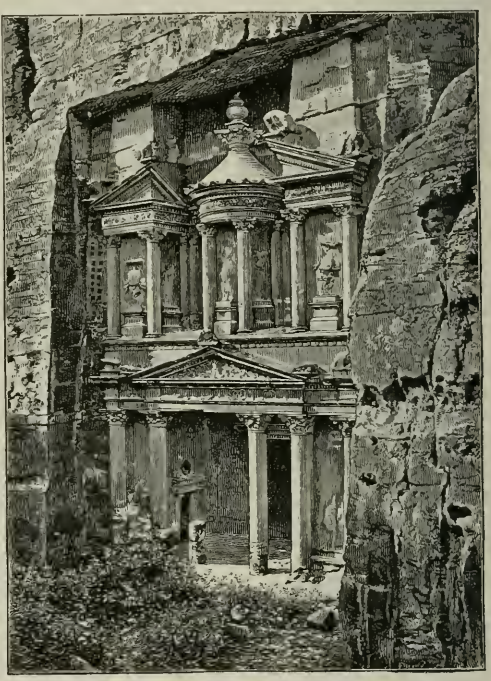
In the United States the right of the people to petition government is expressly secured by the First Amendment of the Constitution, and is thoroughly interwoven with the ideas and usages of the nation—although, during the conflicts on slavery, it was resolved that petitions relating to slavery or the abolition thereof should be laid on the table without being printed or read, and finally that such petitions should not be received at all.

Petition of Right, a declaration of certain rights and privileges of the subject obtained from King Charles I. in his third parliament—the first statutory restriction of the powers of the crown since the accession of the Tudor dynasty. It was so called because the Commons stated their grievances in the form of a petition, refusing to accord the supplies till its prayer was granted. The petition professes to be a mere corroboration and explanation of the ancient constitution of the kingdom; and after reciting various statutes that recognise the rights contended for, prays 'that no man be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by act of parliament; that none be called upon to make answer for refusal so to do; that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge; that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm; that commissions for proceeding by martial law be revoked.' The king at first eluded the petition, expressing in general terms his wish that right should be done according to the laws, and that his subjects should have no reason to complain of wrongs or oppressions; but at length, on both Houses of Parliament insisting on a fuller answer, he gave an unqualified assent on the 26th of June 1628. The text of the Petition will be found most conveniently in Gardiner's *Constitutional Documents of the Puritan Revolution, 1628–60* (1889). See also his *History of England*, vi. 274–309.

Petitio Principii ('a begging of the principle or question') is the name given in Logic to that species of vicious reasoning in which the proposition to be proved is itself assumed in the premises of the syllogism.

Petőfi, SANDOR, Hungarian poet, was born on 1st January 1823 the son of a butcher, at Kis-Körös, in the county of Pesth, and after school-days was successively actor, soldier, and literary hack. His first poem, published in 1842, was followed by a volume in 1844 which secured his fame as a poet. He diligently studied German, French, and English, translated Shakespeare's *Coriolanus*, but in 1848 threw himself heartily into the revolutionary cause, writing numerous popular war-songs. He fell in the battle at Schässburg (Segesvár), 31st July 1849; but it was long believed by the Hungarians that he had escaped, and would reappear. His lyrical poetry breaks completely with the old pedantic style till then in vogue, and, warm with human and national feeling, began a new epoch in Hungarian literature. The first collected edition of his poems appeared in 1874; selections have been translated into English by Bowring and others. There are lives by Opitz (1868) and Fischer (1888).

Petra (the Greek equivalent of the Heb. SELA, both names signifying 'Rock'), anciently the stronghold and treasure-city of the Nabatæans (q.v.), was situated in the 'desert of Edom' in northern Arabia, near the points of intersection of great caravan-routes from Palmyra, Gaza, Egypt, and the Persian Gulf, four days' journey from the Mediterranean and five from the Red Sea. It was approached by a chasm or ravine, which in some places is only 12 feet wide, while the rocky walls of red sandstone tower more than 100 feet above. Along this ravine are the most famous ruin of Petra, the Khusna or 'treasury of Pharaoh,' and a theatre, both shaped out of the solid walls. All along the face of the rocks that overlook the valley are rows of cave-dwellings hewn out of the solid stone, and ornamented with façades. The



Rock Temple at Petra: El Khusna.

floor of the valley, about two miles across, is strewn with ruins. The earliest name was probably Rekem; hence Petra has been identified with Kadesh Barnea, and as the place where Moses struck the rock so that water flowed out. The little stream that descends the ravine, flowing eastwards, has its origin in a spring called at the present day the Fountain of Moses. Petra was captured by the Romans in 105 A.D., and thereafter decayed, its place as a commercial centre being taken by Palmyra (q.v.). Nevertheless it continued to exist as a town; most of the ruined edifices belong probably to the first century of its decay.—It is from Petra, and not from the Greek word *petra*, that Arabia Petræa gets its name.

See De Luynes, *Voyage d'Exploration* (1875); Laborde and Dinant, *Arabie Petrée* (1830–34); Palmer, *Desert of the Exodus* (1871); Stanley, *Sinai and Palestine* (1866); and other works cited at EDOM.

Petrarch. Francesco Petrarca, one of the earliest and greatest of modern lyric poets, was the son of a Florentine notary, Petracco (diminutive of Peter) di Messer Parenzo, the name of Francesco Petrarca by which the poet is known being the Latinised form of Francesco di Petracco—viz. Francis of Peter. Petrarch's father was exiled from Florence (1302) along with Dante during the struggles between the two factions of the Bianchi and Neri, when the latter party obtained the upper-hand. He took refuge with his family in Arezzo, where, on the 20th July 1304, Francesco was born.

The poet's infancy was passed in Tuscany until 1312, when his father determined to go to Avignon, whither the papal court had lately been transferred. There and in the neighbouring small town of Carpentras Petrarch's studies began, and were continued later at Montpellier and Bologna. His father intended him to enter the legal profession; but instead of jurisprudence he devoted himself with enthusiasm to the study of the classics, his favourite authors, on whose style he afterwards strove to model his own, being Cicero and Virgil. It was only later in life that he tried to learn Greek, in which he never attained to any proficiency. After his father's death, whom his mother did not long survive, Petrarch returned to Avignon (1326). As was the custom of the time, more especially at the papal court, he and that brother Gherardo, being without means, became ecclesiastics; but Francesco never took holy orders. His chief source of income became the small benefices conferred on him by his many powerful patrons; but in after-life he refused higher preferment, declining even the much-coveted post of papal secretary, rather than compromise his independence. Petrarch is reported to have been a handsome young man of winning manners, fond of rich clothing and all the refinements of court-life. It was at this period of his life that he first saw Laura, the lady whose name he was to immortalise in his lyrics, and who inspired him with a passion which has become proverbial for its constancy and purity. The meeting took place on April 6, 1327, in the church of St Clara at Avignon. This date, as well as that of Laura's death on the same day in the year 1348, stands recorded by Petrarch's own hand on the fly-leaf of his Virgil, now amongst the treasures of the Ambrosian Library at Milan. The identity of Laura has been a subject of much discussion, the most generally accepted hypothesis is that of the Abbé de Sade, who identified the poet's love, on somewhat slender evidence, with a member of his own family, Laure de Noves, married in 1325 to a Hugo de Sade; she became the mother of eleven children, and died in April 1348. It was also at this time that Petrarch's friendship began with the powerful Roman family of the Colonnas, and especially with Jacopo Colonna, Bishop of Lombez.

The dawn of the new birth of letters and art which was to illumine the following century was already altering the status of the poet and artist, and as the fame of Petrarch's learning and genius grew his position became one of unprecedented consideration. His presence at their courts was competed for by the most powerful sovereigns of the day, and such was the exceptional position he enjoyed that he has said of himself that princes had lived with him, not he with princes. His chief patrons were Pope Clement VI., the Emperor Charles IV., King Robert of Naples, the Viscontis of Milan, Jacopo da Carrara, Lord of Padua, Azzo da Correggio, Lord of Parma; in Venice the senate bestowed a palace on him in return for his promise to leave that town his library; Florence offered him the restoration of the confiscated possessions of his family if he would reside there, and in Arezzo the house where he was born was held as a sanctuary. When wearied by court-life he sought retirement and quiet in his country-house at Vaucluse, near Avignon. He travelled repeatedly in France, Germany, and Flanders, wherever he went searching diligently for manuscripts to enrich his collection. He made some valuable bibliographical discoveries, finding in Liége two new orations of Cicero, in Verona a collection of letters of the same writer, and in Florence a then unknown Institution of Quintilian's. In the cosmopolitan society of the papal court Petrarch became acquainted with learned men of all countries, whom he interested in his unwearied search for valuable manuscripts. The example given by Petrarch in his loving preservation of books probably gave the first incentive to the collection of manuscripts which bore such rich fruits in the following century. But the most glorious moment of Petrarch's honoured career was when, invited by the senate of Rome on Easter Sunday, 1341, he ascended the capitol clad in the robes of his friend and ardent admirer, Robert of Anjou, king of Naples, and there, after delivering an oration on poetry and the significance of the laurel, he was crowned poet-laureate amid the acclamations of thousands. After this pagan ceremony he went to leave his crown on the altar of St Peter's. In 1353, after the death of his beloved Laura and his friend Cardinal Colonna, he left Avignon for ever, disgusted with the corruption and vice of the papal court. The remaining years of his brilliant life were passed in various towns of Northern Italy, and in the retirement of a country-house at Arquà, near Padua, the only one of his many habitations still in existence. There, tenderly cared for by his natural daughter, Francesca, and her husband, and occupied to the last in his favourite studies, he quietly ended his life, 18th July 1374.

Petrarch may be considered as the earliest of the great humanists of the Renaissance and the founder of modern classic culture. His passionate admiration for antiquity and the classic authors was no longer that of Dante and the earlier writers, whose erudition was incorporated with the feelings and needs of their own time and stamped with their own individuality. The more contemplative and less original mind of Petrarch lent itself rather to an entire withdrawal from and disdain for all that later times had produced, and his constant effort was to imitate as closely as possible the modes of thought and expression of the great Latin writers. He attained to a surprising purity of style in his Latin works, and the admiration which these writings excited in his contemporaries was boundless. Petrarch himself chiefly founded his claim to posthumous fame on his epic poem *Africa*, the hero of which is Scipio Africanus, and his historical work in prose, *De Viris Illustribus*, a series of biographies of classical celebrities. His other important Latin works are the eclogues and epistles in verse; and in prose the dialogues, *De Contemptu Mundi* and *Secretum*, and the treatises *De Otio Religiosorum* (written while visiting his brother, who had joined a Carthusian brotherhood) and *De Vita Solitaria* (written at Vaucluse); and particularly important for historical and biographical purposes is the numerous collection of letters divided into *Familiares*, *Variæ*, *Ad Veteres Illustres*, *Seniles*, and *Sine Titulo*.

Petrarch was an ardent patriot, but he had little practical influence on the political life of his time. His ideas were those of a poet, and not of a statesman. However great his merits as patriot or student, his name would be little remembered now; it is by his lyrics alone that his fame has lasted for over five centuries. His title-deeds to fame are in his *Canzoniere*, in the sonnets, madrigals, and songs written in Italian, almost all inspired by his unrequited passion for Laura, and in which the character of the man and the reality of a strong sentiment find their expression. The history of Petrarch's love presents few incidents; its entire interest is psychological. In these poems we see the picture of a human soul in all its contradictions, pains, and struggles. Such self-analysis was unknown in mediæval writers, and Petrarch has therefore been called the first *modern* man. His last work was an allegorical poem in 'terzine,' *I Trionfi* ('Triumphs'), also in Italian, and is of unequal merit, the only remarkable

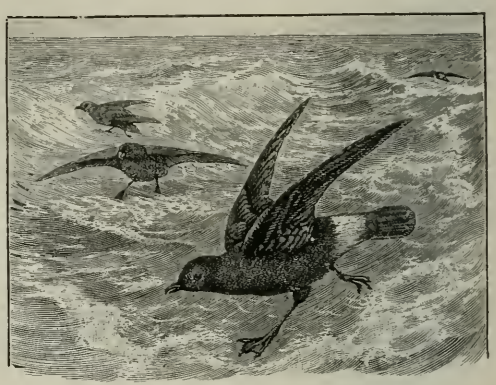
passages being those which refer to the beginning of the poet's love ('Triumph of Love') and to Laura's death ('Triumph of Death'). Few of Petrarch's lyrics treat of other subjects, but amongst these few are three of his finest efforts—one, the famous address to his country (*Italia mia*), in which he reproaches the Italian princes for their dissensions, and for calling to their aid the mercenary 'barbarians' who were the scourge of Italy, words repeated by Machiavelli in his *Prince*, a century and a half later, and in our own day in the struggle for freedom from Austria; the second (*Spirto Gentil*), which some commentators consider to be addressed to the young Colonna, and others to the famous Cola di Rienzi, whose wild attempt to resuscitate the ancient forms of republican government in Rome had fired Petrarch with enthusiasm; and the third (*O Aspettata in Ciel Beata e Bella Anima*), addressed to his friend Jacopo Colonna, to incite him to join the crusade of Philip of France against the infidels. Petrarch was in constant correspondence with his great contemporary, Giovanni Boccaccio (*Lettere di Boccaccio*, ed. by Corazzini, Florence, 1877), and translated into Latin his friend's tale of Patient Griselda (*De Obedientia ac Fide Uxoria*). Chaucer alludes to this when he says of his Clerk's Tale:

> Lerned at Padowe of a worthy clerk,
> Fraunceys Petrark, the laureat poete,
> Highte this clerk, whose rethorike swete
> Enlumined al Itaille of poetrye.

The earliest complete edition of Petrarch's works is *Francisci Petrarchæ Opera Omnia* (Basel, 1554, fol.). His Italian lyrics were published as early as 1470 (Venice, 4to), and have since gone through innumerable editions with or without commentary. The most reliable is that of Marsand (Padua, 1819, 4to); his text is used by Leopardi for his important edition and commentary (Milan, 1826), often reprinted. The letters have been edited by Fracassetti, and partly translated into Italian, with a valuable commentary (Florence, 1859-63-69). See the Abbé de Sade, *Mémoires de Petrarque* (1764); Mezière, *Petrarque* (1868); Koerting, *Petrarcas Leben und Werke* (1878); the little monograph by Henry Reeve (1878); also Gaspary, *Italienische Literatur* (Berlin, 1885); Bartoli, *Letteratura Italiana* (Florence, 1884); De Sanctis, *Saggio sul Petrarca* (Naples, 1869); Zumbini, *Studii sul Petrarca* (Naples, 1878); Voigt, *Wiederbelebung des classischen Alterthums* (Berlin; 2d ed. 1880); and Symonds, *Renaissance in Italy* (1875-86).

Petre, an English Catholic family, descended from Sir William Petre, secretary of state in the reigns of Henry VIII., Edward, Mary, and Elizabeth. The most notable member was Edward Petre the Jesuit (1631-99), who shared the captivity of his kinsman Lord Petre in the Tower in connection with Oates's 'Popish Plot,' but released by James II. sat in the Privy-council. He was abhorred as James's evil genius, and escaping at the Revolution became rector of St Omer.

Petrel (*Procellaria*), a genus of sea-birds of the family Procellariidæ, which includes the albatrosses, shearwaters, fulmars, and petrels proper, and is allied to the gulls (Laridæ). The true petrels, of which there are eighteen widely distributed species, are long-winged birds of powerful flight; the tail is broad and of medium length; the hind toe is very small; the claws are narrow and pointed; the bill is short and slender, and the tube-like nostrils are set close together. They are strictly oceanic, and visit coasts and islands only for breeding purposes. The best-known species is the Stormy Petrel (*P. pelagica*) or Mother Carey's Chicken (q.v.), which is scarcely larger than a lark, and is the smallest web-footed bird known. The head and back are sooty-black, the wings black, with streaks of white, the under surface grayish black, the bill black, and the feet reddish brown. The name Petrel—a diminutive of Peter—refers to its apparent walking on the water, the lightness of its body enabling it to skim up and down the waves, even in a storm, with only enough motion of the wings to keep the feet from sinking under the surface. Because of its frequent occurrence before or during stormy weather, when the molluscs and other animals upon which it feeds are driven to the surface, and possibly also because of its blackness, it is regarded by sailors as a bird of evil omen.



Stormy Petrel (*Procellaria pelagica*).

Its flesh is so oily that the Faroe islanders, it is said, draw a wick through the body to make a lamp. See FULMAR.

Petri, LAURENTIUS, Swedish Reformer, was born at Örebro in 1499, studied under Luther at Wittenberg, was made professor of Theology at Upsala, and in 1531 first Protestant Archbishop of Upsala, and died in 1573. Along with his brother Olaus he was chiefly instrumental in converting Sweden to the Reformed doctrines, and with him superintended the translation of the Bible into Swedish (1541), a work that also helped to fix the language.—His brother OLAUS, born at Örebro in 1497, died at Stockholm in 1552, gained, a few years after his return (1519) from Wittenberg, the ear of Gustavus Vasa, who called him to the capital to preach the new doctrines, and eventually made him (1531) chancellor of the kingdom. This post he resigned in 1539, and spent the rest of his life as first pastor of Stockholm. He was a man of bold temperament, great activity, and powerful eloquence, and left several works, including memoirs, a mystery-play, hymns, and controversial tracts.

Petrie, GEORGE, a learned Irish archæologist, was born at Dublin in January 1790, son of a portrait-painter from Aberdeen. He studied art, and became famous for his Irish landscapes, but gave from the beginning the half of his heart to his favourite study. In 1828 he was set over the short-lived antiquarian and historical section of the Ordnance Survey of Ireland, and in 1832 he became editor of the *Dublin Penny Journal*. He was made LL.D. by Trinity College, Dublin, in 1847, received a Civil List pension of £300 in 1849, and died January 17, 1866. Petrie's admirable *Essay on Round Towers* received the Irish Academy's prize in 1830. It remains a work of the very greatest value. All antiquaries accept its theory that the round towers were Christian ecclesiastical buildings of various date. Other writings are an *Essay on the Military Architecture of Ireland* and *History and Antiquities of Tara Hall*. See the study by William Stokes (1868).

Petrie, WILLIAM MATTHEW FLINDERS, was born at Woolwich, 3d June 1853, and educated

privately. His earliest explorations bore fruit in his *Stonehenge* (1880), and he next turned his attention to the pyramids and temples of Ghizeh (book, 1887), subsequently, with the aid of the Egypt Exploration Fund, to the mounds of Said—the Scripture Zoar, the forgotten city of Naukratis, Am, and Defenneh. His *Memoirs* on Tanis (1885-89), on Naukratis (1886), on Tel el Hesy, the site of Lachish (1891), on *Medum* (1892), and on *Ten Years' Diggings* (1892), are all important.

Petrifaction, a name given to organic remains found in the strata of the earth, because they are generally more or less mineralised or made into stone. The word has fallen very much into disuse, having given place to the terms Fossil (q.v.) and Organic Remains. The name petrifaction is also loosely used of an object which, from being exposed to the action of limy or other water, becomes covered with a crystalline deposit. See Fossil Forest, Wood (Petrified).

Petro-Alexandrovsk, the seat of administration of the Amû-Daria district, is little more than a fort, and is situated on the Lower Amû-Daria or Oxus (q.v.), 30 miles E. of Khiva.

Petrography is that branch of geological science which deals with rocks viewed as aggregates of mineral matter. It is a study, therefore, which is carried on chiefly indoors, its object being to ascertain the mineralogical composition, the texture, and other physical characters of rocks, for which various appliances and apparatus are required. Although petrography is properly only a description of rocks, it is hardly possible to describe rocks without reference to their geological relations and mode of origin. Hence by many geologists the term Petrology is preferred as a name for this branch of their science, while others use Lithology in a similar sense. For a general account of rocks from the point of view of their origin, reference may be made to the section Petrology under Geology.

Petrographers are hardly yet agreed on any particular classification of rocks, not certainly from the want of materials, for a very large number of so-called rock-species have been described. But in the case of the crystalline igneous rocks so many gradations exist between one kind and another that the definition of rock-species is often very difficult. As careful descriptions multiply and comparisons are made it is probable that many of the igneous rocks which flourish at present as species will come to be included as mere varieties of a few well-marked types.

In examining a rock the petrographer notes first those characters which can be seen by the naked eye (*macroscopic characters*), such as its structure (whether *crystalline*, *vitreous*, *compact*, or *elastic*, &c.); its state of aggregation or relative hardness; its colour; its composition; and specific gravity—which may vary from 0·6 among the hydro-carbon compounds to 3·1 among the basalts, the average specific gravity of rocks in general being about 2·5 or a little more. In the case of many coarse-grained rocks, especially those belonging to the derivative division, it is hardly requisite to go beyond a macroscopic examination. But when the rock appears to be homogeneous it is necessary to subject it to closer scrutiny. Thin slices are therefore prepared for microscopic study, after which it is frequently found that the apparently smooth compact mass turns out to be composed wholly or largely either of crystalline or of fragmental materials. Even in the case of rocks which are manifestly crystalline, and the mineral ingredients of which can be determined macroscopically, it is necessary that a microscopic examination should be made. When this is done the rock will sometimes be shown to contain minute crystalline granules and crystals, or small quantities of non-differentiated matter and glass which quite escape the unassisted eye. The minute structure of the various rock-forming minerals is likewise investigated by means of the microscope, and the chemical changes which they may have undergone since the time of their formation are carefully studied. In this way much light has been thrown on the genesis of rocks and the changes which these have subsequently experienced.

Of the minerals known to science comparatively few are rock-formers; the larger number of these are practically confined to the igneous and schistose rocks, very few entering into the formation of the derivative class. The mineral constituents of the igneous rocks are grouped as *essential*, *accessory* or *adventitious*, and *secondary*. The essential minerals are the most important, as it is upon their presence that the various species of rocks depend. Accessory minerals are accidental ingredients, the presence or absence of which does not affect the specific character of a rock; if sufficiently prominent or remarkable they merely give rise to varieties. Secondary minerals are the products of chemical changes subsequent to the formation of the rock in which they occur—the essential and accessory minerals being *primary* or *original* constituents. Among the more important essential minerals of *igneous* rocks are quartz, felspar, nepheline, leucite, pyroxene, hornblende, mica, and olivine. All these also occur as accessory ingredients, and there are very many other adventitious minerals, but only the following need be named—magnetite, ilmenite (see Iron), apatite, schorl, titanite (sphene), haüyne (nosean), zircon, &c. Amongst the secondary minerals and decomposition products in igneous rocks are quartz, chalcedony, calcite, oxides of iron (see Iron), zeolites, epidote, chlorite, serpentine, green-earth, &c. The chief mineral constituents of the *Schistose* rocks are the following: Quartz, mica, felspar, talc, chlorite, hornblende, actinolite (see Amphibole), omphacite, smaragdite. Less prominent ingredients are andalusite and chiastolite, staurolite, ottrelite, kyanite, magnetite, schorl, sphene, epidote, pyrite, specular iron, &c. The *derivative* rocks having been formed out of the debris of pre-existing rock-masses, whether igneous, schistose, or sedimentary, it is obvious that they may contain many of the minerals already mentioned. Thus, there are some sandstones composed of quartz, felspar, and mica—the debris of granite or gneiss. But most of the minerals which aqueous rocks have derived from crystalline igneous and schistose rocks are more or less altered—the felspars are kaolinised, the micas are reduced to non-elastic scales or folia of a dull gray colour and much diminished lustre, the pyroxenes, amphiboles, olivine, &c. are either unrecognisable or represented by decomposition products. Quartz, as might have been anticipated, owing to its resistance to the chemical action of water and its superior hardness, is the most common mineral constituent of derivative rocks. The clay-rocks consist in large measure of the insoluble residue of the various silicates of alumina and the alkalies and alkaline earths, of which igneous and schistose rocks are so largely composed. The readily soluble and readily precipitated minerals calcite, dolomite, rock-salt, and gypsum are also important rock-formers in certain groups of derivative rocks. As binding materials (i.e. the mineral cements which hold the grains of many sedimentary rocks together) we have quartz, chalcedony, opal, &c., calcite, hæmatite, and limonite (see Iron), dolomite, siderite, &c. The rocks which are mainly composed of organic debris necessarily consist chiefly of calcareous and carbonaceous materials.

For purposes of description rocks may be grouped in the three following divisions: (I.) Igneous Rocks; (II.) Derivative Rocks; and (III.) Schistose Rocks.

I. *Igneous Rocks* (q.v.).—Of these there are two series—(*a*) *crystalline* and (*b*) *fragmental* or *clastic*. The crystalline series includes semi-crystalline and vitreous or glassy rocks, some of the more important characters of which may be noted. The vitreous rocks usually contain crystallites and microlites, and they often show perlitic and spherulitic structures. Some varieties are highly porous and froth-like (see PUMICE). Others are more or less homogeneous, closely compact, and smooth like bottle-glass; while yet others are markedly porphyritic, usually with crystals of sanidine (see FELSPAR). Such vitreous rocks are most usually acidic (i.e. highly siliceous), but basic glasses are also known. The semi-crystalline rocks are composed of crystalline minerals and glassy matter in very variable proportions. The crystalline ingredients often show minute inclusions of other minerals (*endomorphs*) or of glass, &c., which have been caught up while the crystal was growing in its molten magma. Frequently also the crystals contain minute cavities which may be empty or filled with some liquid or gas. The wholly crystalline rocks contain of course no glass or non-differentiated matter. It is in this class of rocks—many of which are of plutonic origin—that liquid cavities are of most common occurrence in the constituent minerals. In the minerals of semi-crystalline and crystalline rocks which have been erupted at or near the surface liquid cavities are less common. In vitreous, semi-crystalline, and crystalline rocks alike the mineral ingredients are not seldom disposed in lines or bands. This is called *fluxion* or *fluidal* structure—the ingredients having arranged themselves in this manner while the igneous rock was fluid and in motion. Although not unknown in some holocrystalline rocks, it is a structure which is more characteristic of the vitreous and semi-crystalline rocks which have been poured out at the earth's surface as lavas. The appearance of the original mineral constituents of many igneous rocks shows that their crystallisation cannot have taken place contemporaneously. In most cases it can be shown that they belong to two stages in the consolidation of the rock of which they form a part. Thus, in many crystalline and semi-crystalline rocks we readily distinguish a crystalline or semi-crystalline ground-mass, scattered through which occur larger crystals, many of which may be broken and corroded. These latter are believed to have crystallised while the molten rock was still at a considerable depth below the surface. Afterwards, when the fluid mass was poured out at or near the surface, and cooled rapidly, the smaller minerals and glassy matter of the ground-mass were formed. Although these two classes of minerals can be seen most clearly in rocks of a trachytoid and porphyritic aspect, yet even in granitoid rocks evidence of two stages or periods of consolidation can often be detected. The general character of fragmental igneous rocks is discussed under AGGLOMERATE, TUFF, and IGNEOUS ROCKS. Most of the rocks mentioned in the following tables have separate articles assigned to them.

(*a*) *Vitreous and Crystalline Series:*

1. ORTHOCLASE ROCKS: obsidian, pitchstone (structural varieties of vitreous rocks, as perlite, spherulite rock, pumice), phonolite, trachyte, liparite, orthoclase-porphyry, quartz-porphyry, syenite, granite.
2. PLAGIOCLASE ROCKS: andesite and porphyrite, diorite, basalt, gabbro.
3. FELSPATHOID ROCKS: nepheline-basalt, leucite-basalt.
4. OLIVINE ROCKS or PERIDOTITES: picrite, lherzolite, dunite, &c.
5. ALTERED IGNEOUS ROCKS: various serpentine rocks.

(*b*) *Fragmental or Clastic Series:*

Volcanic agglomerate, volcanic breccia, tuff; volcanic sand, ashes, dust, blocks, lapilli, and bombs.

II. *Derivative Rocks.*—As water has played a very prominent part in the formation of this great division of rocks, these are frequently termed *aqueous* or *sedimentary*. Such being the origin of by far the greater number, we find that they generally occur in layers or beds, hence the name by which they are also widely known—*stratified* rocks. Some of the members of this division, however, are not of aqueous origin, while others do not occur in beds. But they are all alike in so far as the materials of which they consist have been derived by epigene agents from the degradation of pre-existing rocks, minerals, and organic bodies.

1. GRAVEL AND SAND ROCKS: rock-debris and breccia; rain-wash and brick-earth; soil and subsoil; shingle and gravel, conglomerate; sand, sandstone, and grit; greywacke.
2. CLAY ROCKS: kaolin, pipeclay, fireclay, brick-clay, fuller's earth, boulder-clay or till, loam, mudstone, argillaceous shale.
3. CALCAREOUS ROCKS: limestone and its many varieties (such as calc-sinter, chalk, oolite, marl, coral-rock, &c.), dolomite or magnesian limestone.
4. IRONSTONE ROCKS: limonite, hæmatite, spathic iron ore (sphæro-siderite, blackband ironstone), magnetic iron ore.
5. SILICEOUS ROCKS: siliceous sinter, flint (chert, hornstone, lydian stone, jasper, &c.), tripoli and radiolarian ooze.
6. PHOSPHATIC ROCKS: bone-breccias, guano, coprolites.
7. CARBONACEOUS ROCKS: peat, lignite, coal and its varieties, anthracite, oil-shale, petroleum, asphalt.
8. GYPSUM AND HALITE GROUP: anhydrite, gypsum, and rock-salt.

III. *Schistose Rocks.*—The more representative rocks of this division are more or less crystalline and schistose or foliated (see FOLIATION). Some, however, show faint traces either of crystalline or foliated structure; while others, although distinctly crystalline, are not schistose. Again, some of the rocks are fragmental, with more or less of superinduced crystalline structure. Many schistose rocks are clearly of metamorphic origin. They are altered igneous and derivative rocks. The origin of others is still obscure. See ARCHÆAN SYSTEM, GEOLOGY.

Quartz-rock, quartz-schist, hälleflinta, schistose conglomerate, clay-slate and its varieties, phyllite, mica-schist, talc-schist, chlorite-schist, amphibole-schist (actinolite-schist, hornblende-schist), gneiss, granulite, eclogite, garnet rock, marble.

See Rutley, *The Study of Rocks* (1879); Hatch, *Petrology* (1891); Cole, *Aids in Practical Geology* (1891); Lasaulx, *Einführung in die Gesteinslehre* (1886); Kalkowsky, *Elemente der Lithologie* (1886); Jannettaz, *Les Roches* (1884). More advanced works are Teall, *British Petrography* (1888); Fouqué and Lévy, *Minéralogie Micrographique* (1879); Rosenbusch, *Mikroskopische Physiographie d. Mineralien u. Gesteine* (1885); Zirkel, *Mikroskopische Beschaffenheit d. Mineralien u. Gesteine* (1873).

Petroleum (rock-oil, from Lat. *petra*, 'rock,' and *oleum*, 'oil'), an inflammable liquid, essentially composed of carbon and hydrogen, which exudes from the earth in various parts of the world.

Copyright 1891 in U.S. by J. B. Lippincott Company.

(1) *General History.*—It is impossible to state when petroleum was first discovered. In some form it seems to have been applied to the uses of mankind in the earliest periods known to history. The ruins of Nineveh and Babylon indicate that the asphaltic mortar used for their walls and buildings was made from a partially evaporated petroleum, obtained, doubtless, from the springs of Is, on the Euphrates. This is probably the 'slime' of the Old Testament Scriptures (Gen. xi. 3). Herodotus (i. 119; iv. 195), 500 B.C., writes of the springs in the island of Zante, 'I have myself seen pitch drawn out of a lake and from water in Zacynthus,' &c. Strabo (xvi. 2) refers to the bitumen found in the valley of Judea, and sold to the Egyptians for embalming.

Diodorus describes the same product obtained from a lake in Sicily and sold for the same uses. Pliny, Plutarch, Aristotle, and Josephus mention the deposit in Albania on the Adriatic Sea. The holy fires of Baku on the Caspian Sea, worshipped for ages by the people dwelling near, and the goal of pilgrimages even from India (see Vigne's *Travels in Cashmir and Little Thibet*), have been sustained by apparently inexhaustible petroleum stores. The North American Indians collected what was known as Seneca Oil from petroleum springs, and the indications are that long before them the Mound Builders, who worked the copper-mines of Lake Superior, the lead-mines of Kentucky, and the mica-mines of North Carolina, not only gathered the oil coming from natural springs that appeared on streams, but even dug numerous wells in Pennsylvania, Ohio, and Canada, and dipped up the oil that flowed into them. Trees now growing in the earth thrown out in digging the wells, or in the wells themselves, show that the work was done from 500 to 1000 years ago.

(2) *Growth of the American Industry.*—But the growth of the American industry, which has given the world what can be fairly termed the people's light, has been within the last half of the 19th century. From 1850 to 1858 many experiments were made with petroleum, both in the line of collecting the crude article and of refining it when secured, but with indifferent success. Among the promoters of these efforts was the Pennsylvania Rock-oil Company, incorporated in 1854 under the laws of the state of New York. The superintendent of this company, E. L. Drake, in 1858 started to sink a well in one of the old pits supposed to be of prehistoric origin, near Titusville on Oil Creek, Venango county, Pennsylvania. Water and quicksand choking this open well, he decided to drive an iron pipe from the surface of the ground down to the solid rock. On August 28, 1859, after going to a depth of 34 feet, he found that oil rose nearly to the top of his pipe at the surface of the ground. He had 'struck oil!' In the general excitement that followed this successful venture wells were sunk in great numbers along Oil Creek, French Creek, and the Alleghany River. Adventurers and investors flocked thither from all parts of the country. What was soon known as the 'oil region' was transformed from an almost unbroken forest into camps and towns in which fortunes were made in a day, and often as quickly squandered. Many wells yielded nothing, others lasted but a short time, while some gave enormous quantities of oil. But the producing fields were, and are still, constantly changing; new ones being discovered, old ones failing. For example, Pithole City, near Titusville, Pennsylvania, in 1865 next to Philadelphia the largest post-office in Pennsylvania, has now entirely disappeared, and the site of the city become a farm. Crude petroleum is at present secured in many parts of the state of Pennsylvania. Special mention might be made of M'Kean, Warren, Elk, Forrest, Erie, Crawford, Venango, Clarion, Butler, Washington, and Greene counties. It is also produced in some parts of other states—New York, Ohio, West Virginia, Indiana, Colorado, Wyoming, Kentucky, California, and Texas. Traces of petroleum are found also in many other of the United States.

Between 1890 and 1897 the product of petroleum in the United States doubled, the production in 1897 being 60,568,081 barrels, of a value of $40,929,611; while the export of mineral oils had a value of over $56,125,000. In the same year the United Kingdom imported 185,665,376 gallons, valued at £3,335,271. The use of petroleum for fuel, as in motor-cars (see GAS-ENGINE) has of late greatly extended.

The accompanying table gives the production of crude oil in the United States, the stocks, and the prices realised at the wells for each year, 1861 to 1890 inclusive. The unit of measurement of crude oil is a barrel of 42 gallons.

Year.	Production.	Shipments.	Stock, close of Year.	Price at Wells.
1861	2,113,600	1,650,133	Unknown	$0.52
1862	3,056,606	3,101,571	"	1.00
1863	2,611,359	3,242,951	"	3.11
1864	2,116,182	1,842,061	"	7.85
1865	3,497,712	2,100,132	"	6.65
1866	3,597,527	3,010,921	"	3.76
1867	3,346,306	2,893,210	534,000	2.40
1868	3,715,741	3,482,510	264,805	3.57
1869	4,186,475	4,255,343	340,154	5.64
1870	5,308,046	5,593,168	537,751	3.86
1871	5,278,072	5,667,891	568,858	4.42
1872	6,505,774	5,899,942	1,174,000 Est.	3.96
1873	9,849,508	9,499,775	1,625,157	1.73
1874	11,102,114	8,821,500	3,705,639	1.18
1875	8,948,749	8,924,938	2,751,758	1.24
1876	9,142,940	9,583,949	1,926,735	2.51
1877	13,052,753	12,469,644	2,857,098	2.38
1878	15,011,425	13,750,030	4,307,590	1.16
1879	20,085,716	16,226,586	8,094,496	.88
1880	24,788,950	15,839,020	16,606,344	.94
1881	29,674,458	19,340,021	25,333,411	.85
1882	35,789,190	22,094,209	34,335,147	.78
1883	34,385,966	21,967,636	35,715,565	1.05
1884	23,596,945	24,053,902	36,872,892	.83
1885	21,600,651	24,029,424	33,836,939	.88
1886	25,854,822	26,332,445	33,395,885	.71
1887	21,818,037	26,627,191	28,310,282	.66
1888	17,461,869	27,157,108	18,634,889	.87
1889	22,715,592	30,496,396	10,923,442	.94
1890	30,293,545	31,601,847	9,472,432	.86

There are no reliable statistics showing the number of producing wells in existence. It is estimated by those best informed on the subject that in what is known as the Pennsylvania fields there were in 1891 between 30,000 and 40,000. At first the wells were of no great depth, extending down to what was termed the first sand. Afterwards wells were sunk to the second and third sands. The average depth is from 1600 to 1800 feet, the shallowest wells being about 500 feet, the deepest about 3000 feet. Many wells, particularly when first completed, are flowing wells; that is, the oil is forced up through the tube composing the well, and reaches the surface of the ground without pumping. This of course indicates that the oil in the reservoir below the surface of the ground is held under pressure; but as an outlet is given for the oil the pressure subsides, and it becomes necessary to lift the oil by pumps. There are to-day a few flowing wells in America, but practically all the wells are pumped. Crude petroleum as it comes from the ground varies in general appearance from a bright lemon colour to a greenish black, all the intervening shades being found, and in gravity (weight or density) from 38 of Baumé's scale to 50, all the intermediate gravities being secured. The same well will, at different stages of its life, give oil of different colours and gravities, the colour growing darker and the gravity heavier as the well grows older. In 1862 it was found that in many cases dry wells could be made to resume their yield, and declining wells to continue production by being shocked with torpedoes. In 1897-98 a commission took evidence in England as to whether petroleum with a flash-point as low as 73° (Abel close test) is dangerous, and reported by a majority that a flash-point at 100° should be taken as the standard of safety. And see EXPLOSIVES.

One of the most interesting features of the growth of the petroleum industry is found in the devices for transportation. The oil was at first carted in barrels over rough roads to the point of consumption or of loading into railroad cars. The wooden barrel gave place to light iron tanks on wheels, and the ordinary freight car for oil in barrels to wooden tank-cars, and these in turn to

iron tank-cars, some of which are of 8000 gallons capacity. But the greatest advance was made when pipe lines for the transportation of petroleum were introduced. Samuel Van Syckle, of Titusville, Pennsylvania, put down the first successful line, extending from Pithole to Miller's Farm, a distance of four miles. The oil region is now a network of pipes. They carry oil from the wells to central points for storage or for delivery to the trunk lines to be pumped to the refineries. Powerful pumps move the oil rapidly in vast quantities for great distances. There are twelve to fifteen trunk lines of 6- and 8-inch pipe, carrying the oil from the point of production to the refineries handling it. The most important lines are known as the National Transit Line, South-west Lines, Macksburg Line, Tidewater Line, Western and Atlantic Line. By these crude oil is delivered at New York, Philadelphia, Baltimore, Cleveland, Buffalo, and Chicago. The total length of these main lines and their several branches and feeders is fully 25,000 miles. The American trade in petroleum is largely controlled by the Standard Oil Company.

(3) *Distillation and Products secured by Distillation.*—The main product of petroleum is refined oil for illuminating purposes. To secure this the crude petroleum is subjected to heat in stills of different sizes and shapes. In most cases the still used is a horizontal cylinder, made of iron or steel plates $\frac{1}{4}$ to $\frac{3}{8}$ inch thick, resting upon, and partly surrounded by, brickwork, as in the case of ordinary cylindrical boilers. A large outlet or vapour-escape pipe carries the vapours over into a long condensing pipe or worm immersed in a vessel containing water constantly supplied to cool and condense the vapours passing through the condenser coil. The first products of distillation are the light gaseous fluids which can be condensed only at very low temperatures, and then kept in liquid form only under pressure. Generally this is not attempted. Then follow in order the various naphtha and refined oil products, until the residuum left in the still represents from 6 to 10 per cent. of the original charge. The yields of the various products varies according to the grade of crude charged in the still, and also somewhat according to the amounts of the different products which the manufacturer finds it most desirable to make. From the different Pennsylvania oils the range of products is as follows: Naphthas, 8 to 20 per cent.; refined oils, 78 to 70 per cent.; residuum, 9 to 5 per cent.; loss, about 5 per cent. From the naphtha many special products are made—gasolenes for lighting, stove-naphtha for cooking, gas-naphtha for gas-making. The refined oil distillates, as they come from the still, are impregnated with tarry matter and inflammable gases, imparting a greenish colour and an offensive odour. To remove the gases the distillate is heated in a still worked entirely by steam. To remove the colour and improve the odour the distillate is then transferred to a large vertical cylinder with a conical bottom, called an agitator, where, by means of an air-blast, the oil is thoroughly agitated with sulphuric acid, resulting in precipitation of much of the objectionable impurities with the refuse acid. The shape of the agitator admits of this refuse being drawn off to go to the acid-restoring factories or to fertiliser works. The distillate is then washed with soda or some other alkali, to neutralise any trace of acid, and with water.

From the residuum left in the still several grades of heavy oils and paraffin-wax are obtained by further distillation in other stills. The oils are used for lubricating purposes, the wax is used for candles. The limits of this article will not admit of even passing mention of the many other by-products secured in the way of lubricating oils, greases, wax, &c. It is safe to say that two hundred different kinds of products are secured from crude petroleum.

While the sale of petroleum products in America is very large, the exports largely exceed the home consumption. The figures below, which show the petroleum exported from the United States in the fiscal years ending June 30, are taken from reports of the Statistical Bureau of the United States Treasury Department at Washington. It will be noted that the total exports for the twenty-seven years 1864–90 have amounted to $1,043,474,435. A larger percentage of the mineral-oil product of the country is exported than of any other product, except cotton.

Year.	Gallons.	Dollars.	Year.	Gallons.	Dollars.
1864	23,210,369	10,782,689	1878	338,841,303	46,574,974

(4) *Petroleum in other Countries than the United States.*—There are oil-fields other than those in the United States producing petroleum in commercial quantities—those of Baku, Burma, Canada, Galicia, Peru, Japan, and, last to be developed, of Langkat, or Lankhat, in Sumatra.

The Baku (q.v.) field yields immense quantities of crude of heavy gravity, which on being distilled gives only a small percentage (25 to 32) of burning oil of satisfactory quality. However, as the crude is very cheap, and the balance of the product from distillation can be sold for fuel, the refiners of the Russian crude have been able to compete with other refiners for a share of the world's trade in petroleum. The petroleum of Canada, like that of several fields in the United States, particularly in the state of Ohio, is of low gravity, 26 to 42 Beaumé, and has a peculiar acrid and nauseous smell, on account of the sulphur it contains. It is difficult to refine, but its production has been fostered, and it supplies a large demand throughout the British provinces. The Japan field has been known for many centuries, but the cheapness of the American refined products renders it impracticable for products from the Japan crude to compete. Production has been completely checked.

(5) *Origin of Petroleum.*—This topic is treated here somewhat out of its natural order, not because it is lacking in interest, but because so little seems to be known about the chemical geology of petroleum. There have been three leading theories advanced, under some one of which all of the results from different lines of investigation can be classed: (1) Petroleum is a distillate produced by natural causes; (2) petroleum is indigenous to the rocks in which it is found; (3) petroleum is a product of chemical action. A full summary of the results of the investigations under each one of these theories is given by Professor S. F. Peckham in his report as special agent of the United States census for 1880. He inclines to the belief that Pennsylvania petroleum is of vegetable origin and the result of distillation.

See also the articles FUEL, GAS, GAS-ENGINE, NAPHTHA.

Petroleuse, a name given to the women of the French Commune of 1871, because they helped to burn the Tuileries, Hôtel-de-Ville, and other public buildings by pouring petroleum on them.

Petromy'zon. See LAMPREY.

Petronel, an ancient and clumsy description of pistol.

Petronius, surnamed 'ARBITER,' from his supposed identity with the Caius Petronius whom Tacitus calls 'arbiter elegantiæ' at the court of Nero, is generally believed to be the author of the satirical romance or collection of satires of which the 15th and 16th books have, though in a fragmentary state, come down to us. The work seems to have been a novelty in Latin literature, consisting of prose and verse, and depicting the licentious life in Southern Italy of the upper or moneyed class. Its artistic merit is great, in strength of portrayal and colour anticipating Zola, with a vein of humour as original as it is refined. Bücheler, its latest and best editor (Berlin, 1882), and Cesareo, its able Italian translator and critic (Florence, 1887), both support the long-prevalent view that its author was no other than the Petronius above referred to—a pro-consul of Bithynia and afterwards consul, a past master in all the arts of the voluptuary, the aider and abettor of Nero and the *jeunesse dorée* of the 1st century in every form of sensual indulgence. The favour he enjoyed at court aroused the jealousy of another confidant of the emperor's, Tigellinus, who had influence enough with their common master to procure his disgrace and banishment. He had proceeded as far as Cumæ, when Nero's casual presence in Campania precipitated his determination to destroy himself. True to the cynical side of his philosophy he set about his suicide in the most leisurely fashion, so as to glide out of existence 'without indecent haste.' He opened his veins at intervals and then rebandaged them, discoursing the while not on immortality or the hollowness of life, but on the gayest of topics, and listening to songs and *vers de société* when not transacting business or taking a siesta. Shortly before expiring he drew up, signed, sealed, and sent to Nero a summary of the tyrant's amours and excesses, much of which is supposed to have been embodied in his satires. The work, fragmentary as it is, has drawn around it quite a library of criticism and controversy, of which Cesareo gives an excellent *résumé*, whilst promising a yet fuller treatise on the subject. In style it represents the high-water mark of silver-age Latinity, while as a picture of the 1st century on its seamiest side it shows better than any other how Christianity had become a necessity, if only to save the morality of the world.

Petropavlovsk, a town of Asiatic Russia, in the province of Akmolinsk, on the river Ishim, 175 miles WNW. of Omsk. Pop. 11,406. It is an important military station, with a fort founded in 1752, and has a large transit trade.—Petropavlovsk is also the name of a small port on the east coast of Kamchatka (q.v.) with an admirable harbour.

Petrovsk, a town of Russia, 65 miles NW. of Saratov, on a tributary of the Don. Pop. 15,316.

Petrozavodsk, a town of Russia, on the western shore of Lake Onega, 300 miles NE. of St Petersburg, has a cannon-foundry and small-arms factory, built in 1774 on the site of an ironwork started by Peter the Great in 1703. Pop. 11,027.

Petrus Alfonsus. See FABLES.

Pettenkofer, MAX VON, chemist, was born near Neuburg on the Danube, 3d December 1818, studied at Munich, Würzburg, and Giessen, and in 1847 became professor of Chemistry at Munich. He has made many valuable contributions to science on subjects as various as gold-refining, gas-making, ventilation, clothing, the influence of soils on health, epidemics, and hygiene generally. His *Handbuch der Hygieine* (1882 *et seq.*) is his best-known work. He resigned in 1894.

Pettie, JOHN, painter, was born at Edinburgh, 17th March 1839, was brought up at East Linton, studied art at Edinburgh, and died at Hastings, 21st February 1893. 'The Prison Pet' was exhibited at Edinburgh in 1859, and 'The Armourers,' at the Royal Academy in 1860. But the first work which showed his characteristic qualities of strong imaginative grasp of his subject, effective composition, and vigorous treatment was the 'Drum-head Court-martial' (1864). Among the hundreds of later pictures, including portraits, may here only be named 'An Arrest for Witchcraft' (1866), 'Scene in the Temple Gardens' (1871), 'Juliet and Friar Laurence' (1874), 'The Death Warrant' (1879), 'The Vigil' (1884), and 'The Chieftain's Candlesticks' (1886). Pettie was elected A.R.A. in 1866, and R.A. in 1873.

Petty, SIR WILLIAM, a man of singular versatility, best known as a political economist, was born at Romsey in Hampshire on 26th May 1623, and educated partly at Caen, partly at the universities of the Netherlands, and at Paris. His versatility and talent are evidenced by the positions he successively held, and the subjects he interested himself in: he taught anatomy and chemistry at Oxford (1648), and was made professor of Anatomy there (1651); was professor of Music at Gresham College, London; was physician to the army in Ireland (1652), executed a fresh survey of the Irish lands forfeited in 1641, started ironworks, lead-mines, sea-fisheries, and other industries on estates he bought in south-west Ireland; was secretary to Henry Cromwell when he was lord-lieutenant of that island; was made surveyor-general of Ireland by Charles II., who knighted him; invented a copying-machine (1647) and a double-bottomed sea-boat (1663); and in early life took much interest in education. In political economy he claims a place as one of the most important precursors of Adam Smith, on the strength of his *Treatise on Taxes and Contributions* (1662) and his *Political Arithmetic* (1691), the latter a discussion of the value of comparative statistics. He died in London on 16th December 1687.

Petty Bag Office, one of the branches of the Court of Chancery, was abolished in 1874, and its duties were transferred.

Petty Officers in the Navy hold a similar rank and position to the non-commissioned officers in the army. They are the backbone of the service, as the efficiency, smartness, and morale of a ship's-company depend in no small measure upon the zeal and discretion of the petty officers. They are now a most highly trained and valuable body of men, and all the warrant officers are drawn from their ranks. They are divided into four classes—viz. chief petty officers, 1st- and 2d-class petty

officers, and leading seamen—and into two branches, the seamen and the so-called non-combatant, which latter includes the artificers, writers, &c. A chief petty officer can only be disrated with the sanction of the commander-in-chief, and in the case of a chief engine-room artificer his disrating must be specially reported to the Admiralty, and he can only be restored to his rank by Admiralty order. All other petty officers can be appointed or disrated by the captain of the ship, except in the case of gunnery or torpedo instructors, who are rated as such for their special qualifications in the gunnery and torpedo schools. The pay of the chief of police (master-at-arms) ranges from 4s. to 6s. a day; that of chief engine-room artificer from 6s. 9d. to 7s. 6d. a day, with an extra penny for each good-conduct badge; a chief gunner or torpedo instructor receives 4s. 2d. a day, with an additional penny for each badge, of which he can have three. A 1st-class petty officer, if a gunnery or torpedo instructor, obtains 3s. 8d. a day, with an extra penny for each badge; if not an instructor, but a trained gunner and torpedo man, 3s. a day; a 2d-class petty officer, if a trained gunner and torpedo man, 2s. 8d. a day, with pay for badges; while a leading seaman receives 2s. 4d. if a trained man, with pay also for badges. A leading stoker receives 2s. 5d. a day, and if a trained mechanic, 2s. 8d.; a carpenter's mate, 4s. 6d.; and a 1st-class writer, 5s. See WARRANT-OFFICERS.

Petunia, a genus of plants of the natural order Solanaceæ, natives of the warmer parts of America. They are herbaceous plants, very nearly allied to Tobacco, and with a certain similarity to it in the general appearance of the foliage, which has also a slight viscidity, and emits when handled a disagreeable smell; but the flowers are very beautiful, and varieties improved by cultivation are amongst the favourite ornaments of British greenhouses and flower-borders. The petunias, although perennial, are very often treated as annuals, sown on a hotbed in spring, and planted out in summer, in which way they succeed very well even in Scotland. They are tall plants, with branching weak stems, and may readily be made to cover a trellis. Though, when treated as greenhouse plants, they become half-shrubby, they live only two or three years. The name is from the Brazilian *Petun*. The first petunia was introduced into Britain in 1831. There are now many garden varieties with double flowers, individually more durable than the single-flowered kinds.

White Petunia (*Petunia nyctaginiflora*).

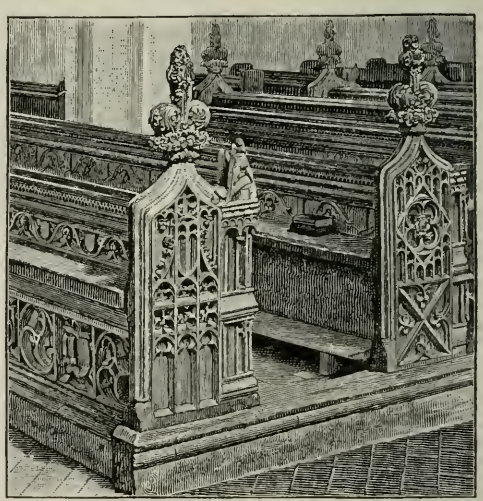
Petuntze. See FELSPAR, POTTERY.

Petworth, a market-town of Sussex, on an eminence near the West Rother River, 14 miles NNE. of Chichester. Petworth House, the seat of Lord Leconfield, is an 18th-century mansion, with a fine park and many portraits and other relics of the Percies and Wyndhams. Pop. of parish, 2942. See F. H. Arnold's *Petworth* (1864).

Peutinger, CONRAD (1465-1547), a scholarly citizen of Augsburg, and keeper of the archives. He published a series of Roman inscriptions; and at his death the so-called *Tabula Peutingeriana* was in his possession, in course of being prepared for publication. This remarkable Itinerary (q.v.) is really a Roman map of the military roads of the 3d century A.D., though his copy was probably a 13th-century one. The document was sold by his family, bought by Prince Eugene in 1714, and is now in the Imperial Library at Vienna. It was edited and published by Scheyb (1753), Mannert (1824), and Desjardins (1869).

Pevensey, a village of Sussex, stands on the English Channel, 12 miles by rail W. by S. of Hastings. The Romans built here a castle, whose walls enclose a Norman keep. The church is Early English. William the Conqueror landed on the shore of Pevensey Bay. Pop. of parish, 365. See Lower's *Chronicles of Pevensey* (3d ed. 1880).

Pews (anciently *pues;* Old Fr. *puys;* Dutch *puyes;* Lat. *podium,* 'anything on which to lean' —*s'appuyer*), enclosed seats in churches. Church-seats were in use in England some time before the Reformation, as is proved by numerous examples still extant, the carving on some of which is as early as the Decorated Period—i.e. before 1400 A.D.; and records as old as 1450 speak of such seats by the name of *pues.* They were originally benches, usually facing east, with partitions of wainscoting about three feet high, and ends of the width of the seat, panelled or carved; these ends often rising above the wainscoting, and ending in fleurs-de-lis or 'poppy-heads,' as shown in the illustration.



Pews, Fressingfield Church, Suffolk.

The benches here are in Fressingfield Church, Harleston, Suffolk, and date from the later half of the 15th century. The back of the one in the engraving is quite a 'poor man's Bible,' being carved with the emblems of the Passion, from the cock crowing to the seamless coat. In later times pews grew into large and high enclosures, containing two or more seats, lined with baize, and fitted with doors, desks, and cushions; but these will soon have all been swept away in England under the influence of the restoration movement and of the Free and Open Church Association founded in 1865 for the abolition of appropriated seats. Pews were early assigned to particular owners, but at first only to the patrons of churches. A canon made at Exeter, in 1287, rebukes quarrelling for a seat in church,

and decrees that none shall claim a seat as his own except noblemen and the patrons. Gradually, however, the system of appropriation was extended to other inhabitants of the parish, to the injury of the poor, and the multiplication of disputes.

The law of pews in England is briefly this. All church-seats are at the disposal of the bishop, and may be assigned by him, by faculty, to persons owning property in the parish. Long occupation may give an owner of property a prescriptive title to a pew. Subject to rights acquired by faculty or prescription, the churchwardens are required to find seats for the parishioners, according to their degree; they may assign a pew to a parishioner, but the right thus conferred may at any time be recalled. In new churches pews may be assigned and pew-rents levied under several acts of parliament. See Dale's *Clergyman's Handbook*. It appears that by common law every parishoner has a right to a seat in the church, and the churchwardens are bound to place each one as best they can. The practice of *letting* pews, except under the church-building acts or special local acts of parliament, and, much more, of *selling* them, has been declared illegal.

In Scotland pews in the parish churches are assigned by the Heritors (q.v.) to the parishioners, who have accordingly the preferable claim on them; in towns the practice is to let them annually. As is well known, pews in dissenting churches are rented as a means of revenue to sustain general charges. In some parts of the United States pews in churches are a matter of annual competition, and bring large sums. Latterly, in England, there has been some discussion as to the injuriously exclusive character of the 'pew system,' and in many churches the open seats or chairs are unappropriated and free to all. In a good many Ritualistic churches the sexes are divided, as in some country churches has been the case with the peasantry since pre-Reformation days. In the Roman Catholic churches on the Continent pews are seldom to be seen.

Pewsey, a small market-town of Wiltshire, in a fertile vale, 18 miles E. of Devizes and 7 SSW. of Marlborough. Pop. of parish, 1895.

Pewter, a common and very useful alloy of the metals tin and lead. See ALLOY.

Pézenas, a town of France (dept. Hérault), on the left bank of the river Hérault, 32 miles by rail SW. of Montpellier. The vicinity produces excellent wine, and woollen and linen goods are manufactured. Pézenas is one of the principal brandy-markets of Europe. Here Molière wrote *Les Précieuses Ridicules*. Pop. 6538.

Pfäfers, hot springs in the canton of St Gall, Switzerland, in the deep and gloomy gorge of the Tamina torrent, which joins the Rhine at Ragatz, 2½ miles to the north. They were discovered towards the middle of the 11th century, and have been used ever since. Patients used formerly to be let down by ropes, but they can now approach by a good road. The water (97° F.) is conducted in pipes to Ragatz, though there are bath-houses (1704) in the ravine. Near the village of Pfäfers (pop. 1628), which stands above and outside the ravine, is a Benedictine abbey, founded in the 8th century, but converted into a lunatic asylum after its dissolution in 1838.

Pfalz, the German name for the Palatinate (q.v.).

Pfalzburg. See PHALSBOURG.

Pfeiffer, IDA (*née* REYER), a celebrated female globe-trotter, was born at Vienna, October 15, 1797. In 1820 she married an advocate named Pfeiffer, from whom she was obliged to obtain a separation. When she had settled her two sons in life, she proceeded to gratify, at the age of forty-five, her long-cherished inclination for a life of travel and adventure. Her first expedition was to the Holy Land in 1842. She published an account of her eastern rambles in the following year, which, like all her other works, went through many editions, and was translated into French and English. In 1845 she visited northern Europe—Sweden, Norway, Lapland, and Iceland—and recorded her impressions in another book, *Skandinavien und Island* (2 vols. 1846). Resolving in 1846 on a voyage round the world, she started from Hamburg in a Danish brig for Brazil. She then sailed round Cape Horn to Chili, thence across the Pacific to Otaheite, China, and Calcutta, traversed India, Persia, western Asia, southern Russia, and Greece, and re-entered Vienna in 1848. Two years later she published a narrative of her travels and adventures, entitled *Eine Frauenfahrt um die Welt* (3 vols. 1850). *Meine Zweite Weltreise* (1856) describes a second journey round the world from England by the Cape to Java, Borneo, California, Peru, and the United States (1851–54). In 1856 she set out on what was to be her last expedition—namely, to Madagascar. After enduring terrible hardships, she got away, and came home to Vienna—to die, October 28, 1858.

Pfleiderer, OTTO, a great philosophic theologian of Protestant Germany, was born at Stetten, near Cannstadt in Würtemberg, September 1, 1839; studied under Baur, at Tübingen, from 1857 till 1861, and next paid a visit of study to England and Scotland; became pastor at Heilbronn in 1868, and superintendent at Jena in 1870, an office which in the same year he exchanged for the chair of Theology there. In 1875 he was called to be professor of Systematic Theology at Berlin. In New Testament criticism Pfleiderer belongs to the younger critical school which has grown out of the impulse given by Baur. But he is not the less an independent thinker, acute, suggestive, and profoundly learned, and he has made his name as well known in England and America as in Germany by a series of works which no serious student of philosophy or theology can afford to overlook. Of these the chief are *Die Religion, ihr Wesen und ihre Geschichte* (2 vols. 1869; 2d ed. 1878); *Der Paulinismus* (1873; 2d ed. 1890; Eng. trans. 2 vols. 1877); *Religions-philosophie auf geschichtlicher Grundlage* (2 vols. 1878; 2d ed. 1883–84; Eng. trans. 4 vols. 1886–88); *Zur religiösen Verständigung* (1879); *Grundriss der Christlichen Glaubens und Sittenlehre* (1880; 4th ed. 1888); *The Influence of the Apostle Paul on Christianity*, the Hibbert Lectures for 1885; *Das Unchristentum* (1887); *The Development of Theology since Kant* (Lond. 1890); and *The Philosophy and Development of Religion*, the Gifford Lectures for 1894.

His brother, EDMUND PFLEIDERER, born at Stettin 12th October 1842, studied at Tübingen, and after a short experience as a pastor was made professor of Philosophy at Kiel in 1873, whence he was called to Tübingen in 1878. His writings include studies on Leibnitz (1870), on Empiricism and Scepticism in Hume's Philosophy (1874), modern Pessimism (1875). Kantian criticism and English philosophy (1881), Arnold Geulinx (1884), Lotze (2d ed. 1884), Heraclitus of Ephesus (1886), &c.

Pforzheim, the chief manufacturing town of Baden, stands at the northern border of the Black Forest, 20 miles SE. of Carlsruhe by rail. It contains the remains of an ancient castle, from 1300 to 1565 the residence of the Margraves of Baden-Durlach, and was the birthplace of Reuchlin. The town is famous for the manufacture of gold and silver ornaments, in which 8000 people are employed, and has further chemical and iron

works, machine-shops, tanneries, paper and other factories. There is a trade in timber, cattle, ornaments, &c. The town was burned by the French in 1689. Pop. (1871) 19,801; (1890) 29,508. See works by Rühl (4th ed. 1888) and Näher (1884).

Phædrus (or PHÆDER, according to some scholars), author of a translation of Æsop's fables in Latin verse, was, by his own account, a Macedonian, who from his childhood was imbued with Greek culture. While still young he came to Italy, and in Rome or some other city attended school where he studied Ennius, whom he quotes in the epilogue to his third book. From the title of the entire work, *Phædri Augusti Liberti Fabulæ*, it appears that from a slave he became the freedman of Augustus, either the first of that name or his successor Tiberius. Under the reign of this latter he published the first two books of his fables, but his biting though veiled allusions to the tyranny of the emperor (in the fable of the frogs asking a king) and to his minister Sejanus (in that of the jay dressed in peacock's plumage) caused him to be hated at court, then accused, and finally condemned—to what punishment is unknown. On the death of Sejanus he resumed publication, and dedicated his third book to one Eutychus, freedman of the Emperor Claudius, courting his protection from enemies and accusers. In the last years of his life, to which the fourth and fifth books belong, he seems to have regained liberty of pen as well as of person. He died probably at an advanced age. Phædrus was more than he claims to be—a reproducer of Æsop; he invented fables of his own, and gave an Æsopic turn to contemporary events. That the five books traditionally ascribed to him are his cannot without large deductions be maintained—not a few of them may be of the same authorship as the *Fabulæ Novæ* commonly added as an appendix to the five books, and found in an anthology attributed to Nicola Perotti, a scholar of the 15th century. The merits of Phædrus are his clear succinct narrative, his pure Latinity, and his skill in versification. The editions of Bentley, Dressel, Orelli, and finally of Müller have been ably gleaned by his latest and most helpful editor Ramorino (Turin, 1884).

Phaëthon ('the shining'), in the writings of Homer and Hesiod, a frequent title of Helios the sun-god, and subsequently employed as his name.—Phaëthon, in Greek mythology, is also the name of a son of Helios, famous for his unfortunate attempt to drive his father's chariot. Scarcely had the presumptuous youth seized the reins, when the horses, perceiving his weakness, ran off, and approaching too near the Earth, almost set it on fire. Whereupon the Earth cried to Jupiter for help, and Jupiter struck down Phaëthon with a thunderbolt into the Eridanus or Po. His sisters, the Heliades, who had harnessed the horses of the Sun, were changed into poplars, and their tears into amber.

Phagedæna. See ULCERS.

Phag'ocytes, the white or colourless blood-corpuscles, which are also called leucocytes. They are active amœboid cells, and engulf both nutritive and harmful particles. Since the researches of Metschnikoff the manifold physiological importance of these elements has been increasingly appreciated. Thus, it is generally recognised that the destruction of invading bacteria is due to the health and activity of the phagocytes. See BLOOD.

Phalacrocorax. See CORMORANT.

Phalæna, the Linnæan genus including Moths (q.v.).

Phalanger (*Phalangista*), a genus of small arboreal marsupials, of which many species are found in Australia and the islands to the north of it. All the species have long, prehensile tails, and many grasp their food and convey it to the mouth with the forepaws. They feed usually on the young shoots and leaves of the trees in which they live, but in captivity they do not refuse animal

Vulpine Phalanger (*Phalangista vulpina*).

food. The Vulpine Phalanger (*P. vulpina*) is very common in Australia, and is used by the natives for food. The Dormouse Phalanger (*P. nana*), which is only six inches in length, resembles the common dormouse in habits and appearance. Closely allied are the Flying Phalangers (q.v.).

Phalanstère. See FOURIER.

Phalanx, the ancient Greek formation for heavy infantry, was a series of parallel columns standing close one behind the other, the whole owing to its depth and solidity capable of penetrating any line of troops. The oldest phalanx was the Lacedæmonian or Spartan, in which the soldiers stood four, six, or, more generally, eight deep. The Macedonian phalanx, the latest form, was sixteen men deep. The arms of the men were swords, shields, and long pikes or spears. The heavy-armed phalanx was ordinarily flanked by *peltastes* or light infantry, similarly formed, who usually fought with javelins and slings.

Phalaris, tyrant of Agrigentum, in Sicily, who flourished about the middle of the 6th century B.C., was born on a small island near Cnidus, in Asia Minor, and whilst building a temple in the citadel of Agrigentum made himself master of the city. He greatly embellished it, and extended his power over large districts in Sicily. But after holding power for sixteen years he was overthrown, for his cruelties, by noble families of the island, and roasted alive in his own invention, the brazen bull. The tradition points probably to the religious sacrifice of human victims to Baal or Moloch (q.v.). Later ages represent Phalaris as a humane and enlightened ruler. But the 148 letters bearing his name were proved by Bentley (q.v.) in 1697 and 1699 to be spurious, and to have been composed several centuries after Phalaris died. See Bentley's *Dissertation*, edited by W. Wagner (Lond. 1883).

Phalarope (*Phalaropus*), a genus of wading-birds forming a sub-family of the Snipes. They are distinguished by their lobed toes, resembling those of the coot. By means of these they swim well, while they can also run swiftly on shore. There are only three species, all inhabiting northern regions, and migrating southward in winter. The Red-necked Phalarope (*P. hyperboreus*), a small bird resembling a Sandpiper in appearance, breeds in the Orkney and Shetland Islands, and the Gray Phalarope (*P. fulicarius*) occasionally visits Britain in the course of its migration farther south.

Phallus, the Greek term for the symbol of generation which figures in the rites and ceremonies of most primitive peoples, and appears as a survival amongst civilised peoples. At the time

when Mythology (q.v.) was universally considered to contain the teaching of ancient sages couched in the form of allegory, and everything in mythology was considered to be 'symbolical' of some profound and hidden truth, phallic worship was naturally conceived to conceal some esoteric teaching as to the mystery of the transmission of life. But this view of mythology is dissipated by an examination of the manner of life and mode of thought of those savage peoples in whom the scientific observer recognises primitive man. The savage leads not a speculative but a practical life, and his rites and ceremonies are practical. He lives in the midst of dangers, which as a practical man he wishes to avert; he has a variety of needs, which as a practical man he wishes to satisfy. Amongst the most important of his needs—whether he be in the pastoral or the agricultural stage—is the need of fruitful flocks, of fertile fields. Amongst the means which he employed to secure fertility were some which we should discriminate as magical, though probably to him they originally seemed to be not more supernatural or less rational than ploughing. Thus, it has been proved to demonstration by Mannhardt that one of the beliefs most widely spread amongst primitive men is the belief in a spirit of vegetation. The tree is regarded first as having life like a man, then as being the abode of a spirit, and finally the spirit ceases to be permanently attached to the tree. The savage has special means for promoting the vigour, for preventing the decay, for averting the displeasure of these spirits on whom the fertility of his crops depends. These various means are usually of the nature of what has been termed 'sympathetic magic.' Even civilised man, if he is abroad and is ignorant of the language of the country, acts what he wishes to have done. In a somewhat similar way the savage performs or mimics the things which he wishes the spirit of vegetation, say, to bring about. When he wishes a spirit to make his flocks multiply, his 'sympathetic magic' inevitably takes the form of a ritual which to us seems obscene, but is to him as harmless and necessary as the act of generation itself. Finally, let it be noticed that, if by 'worship' is meant 'adoration,' then phallic worship is unknown to primitive man; phallic rites and phallic objects are but the means by which, according to his notions, he incites or constrains the spirits to bring about the results he wishes; they are not the symbols of any esoteric mysteries.

Phallus, a genus of fungi. See FUNGI.

Phalsbourg, or PFALZBURG, a town of Lorraine, stands on the north-west shoulder of the Vosges, 25 miles NW. of Strasburg. It was fortified by Vauban in 1680; invested, but not taken, by the Allies in 1814–15; and bombarded and taken by the Germans in 1870, after which they razed the fortifications. It was the birthplace of Erckmann, and is widely known through *Le Blocus* and others of the Erckmann-Chatrian novels. Pop. 3680.

Phanariots. See FANARIOTS.

Phanerogamia (Gr. *phaneros*, 'manifest,' *gamos*, 'marriage') are those plants which bear flowers and produce seeds. But, for the differences and the resemblances between the flowering and seeding of Phanerogams and the reproduction of Cryptogams, see CRYPTOGAMIA, FLOWER, GYMNOSPERMS, SEED. The group includes the following sets of plants: A. Gymnosperms (q.v.), with naked ovules—e.g. conifers; B. Angiosperms (q.v.), with ovules enclosed in ovaries: (1) Monocotyledons (q.v.), with one cotyledon—e.g. lilies, grasses, orchids; (2) Dicotyledons (q.v.), with two cotyledons—e.g. buttercups, roses.

Pharaoh, the English spelling of the name given by the Hebrews to the monarch ruling in Egypt at the time, sometimes as if it were a proper name, though really an official title (from the Egyptian *Peraa* or *Phouro*). The greatest difficulties have been encountered in attempting to determine the particular monarchs who pass under this name in the Scriptures. See EGYPT.

Pharisees (*Perûshim*, 'separated'), a so-called 'Jewish sect,' more correctly a certain Jewish school, which probably dates as a distinct body or party from the time of the Syrian troubles, and whose chief tendency it was to resist all Greek or other foreign influences that threatened to undermine the sacred religion of their fathers. They most emphatically took their stand upon the Law, together with those inferences drawn from its written letter which had, partly from time immemorial, been current as a sacred tradition among the people. They originated as the Chasidim (q.v.), and became known as Pharisees in the time of John Hyrcanus (see MACCABEES). Principally distinguished by their most scrupulous observance of certain ordinances relating to things clean and unclean, they further adopted among themselves various degrees of purity, the highest of which, however, was scarcely ever reached by any member of their community. For every degree a special course of instruction, a solemn initiation, and a novitiate was necessary; all of which, together with a certain distinction in dress, seems to have been imitated from them by the Essenes (q.v.). The name of Pharisees or Perûshim was probably at first bestowed upon them in derision by the Sadducees or Zadokites, the priestly aristocracy and their party, who differed from them politically, and to some extent also in religious matters. The Pharisees had no articles of creed different from the whole body of Jews. The Bible, as interpreted by the traditional Law, was their only code. Obedience to this Law, strictest observance of all religious and moral duties, submission to the Divine will, full confidence in the wisdom and justice of Providence, firm belief in future reward and punishment, chastity, meekness, and forbearance—these were the doctrines inculcated in their schools. They were, in fact, nothing more nor less than the educated part of the people, who saw in the rigid adherence to the ancient religion, such as it had developed itself in the course of centuries, the only means of saving and preserving the commonwealth, notwithstanding all its internal and external troubles. Hence they wished the public affairs, the state and all its political doings, to be directed and measured by the standard of this same Divine Law; without any regard for the priestly and aristocratic families, the Sadducees (q.v.), and the heroes and sagacious statesmen, who had brought the Syrian wars to a successful issue, and had, by prudent negotiations with other courts, restored the nation to its former greatness. The latter held that religion and state were two totally different things: that God had given man the power of taking his matters into his own hands; and that it was foolish to wait for a supernatural interference, where energy and will were all that was required.

Naturally enough, the political difference between the two parties by degrees grew into a religious one. And the more the Sadducees lost their influence (the people siding with the Pharisees), the more the religious gulf must have widened between them; although the divergence between them, as far as our authorities (Josephus, the New Testament, and the Talmud) go, does not seem to have been of so grave a nature as is often assumed. Thus, the Pharisees assumed the dogma of immortality; while the Sadducees held that there was nothing in the Scripture to warrant it, and, above all, that there

was no need of any future reward. While the Pharisees held all the traditional ordinances in equal reverence with the Mosaic institutions, the Sadducees rejected, or rather varied some of these according to the traditions of their own families: these ordinances chiefly relating to priestly and sacrificial observances, certain laws of purity, and some parts of the civil law. It may perhaps even be assumed (as by Geiger) that the Pharisees were the representatives of a newer Halacha, inspired by an oppositional and religious and national zeal which carried them far beyond the original boundaries. Certain other legal differences between the two parties, such as the application of the laws of inheritance to daughters, or of the responsibility of the master for his servants, are nothing more than political party-views in a religious mask, which were meant to meet certain special isolated cases only. In general the Pharisees handled justice in a much milder manner than their antagonists, who took their stand upon the rigid letter, and would hear of no mercy where a violation of the code was clearly made out. Out of the midst of the Pharisees rose the great doctors and masters of the Law (Heb. *shoferim;* Gr. *nomodidaskaloi*, 'teachers of the law,' usually rendered 'scribes'), and to them were entrusted by the later rulers the most important offices. The greatest misconception has prevailed even among scholars respecting this patriotic, pious, learned, and national party of progress. That there were among them those who were a disgrace to their party none knew better than the Pharisees themselves; and, in bitterer words than were ever used by Christ and the apostles, the Talmud castigates certain fanatical members of their own community as the 'plague of Pharisaism.' Pharisaism—from which gradually branched off the wild democratical party of 'Zealots' (*Kannaim*) in the revolution of Bar Cochba (q.v.)—has, from the final destruction of the commonwealth to this day, remained the principal representative of Judaism as a creed.

See JEWS, TALMUD; Schürer's *History of the Jewish People in the Time of Jesus Christ* (Eng. trans. 5 vols. 1886-90).

Pharmacopœia. This term has been applied to various works, consisting for the most part of (1) a list of the articles of the Materia Medica, whether simple or compound, with their characters, their modes of preparation, and the tests for the determination of their purity; and (2) a collection of approved receipts or prescriptions, together with the processes for preparing articles in the Materia Medica. Almost every civilised country of importance has its national pharmacopœia; those of the United States (6th ed. 1883), Germany (3d ed. 1890), and France deserving special mention. The earliest pharmacopœias were prepared by the Arabs from the 9th to the 12th century, and subsequently by the medical school of Salerno. The first pharmacopœia published under authority appears to have been that of Nuremberg in the year 1542. Valerius Cordus, afterwards professor at Wittenberg but then a student, showed a collection of medical receipts, which he had selected from the works of the most eminent writers, to the physicians of Nuremberg. The latter were so struck with its value that they urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the city council. Before this time the books chiefly in use amongst apothecaries were the treatises: *On Simples* by Avicenna and Serapion; the *Liber Servitoris* of Balchasim ben Aberazerim; and the *Antidotarium* of Nicolaus de Salerno, arranged alphabetically. This work was commonly called *Nicolaus Magnus*, to distinguish it from an abridgment known as *Nicolaus Parvus*.

Confining our remarks to the British Pharmacopœias, we may notice that the first edition of the London Pharmacopœia (or, more correctly speaking, of the Pharmacopœia of the London College of Physicians) appeared in 1618, and was chiefly founded on the works of Mezue and Nicolaus de Salerno. Successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1746, 1787, 1809, 1824, 1836, and 1851, and form an important contribution to the history of the progress of pharmacy and therapeutics during the last two centuries and a half. The nature and the number of the ingredients that entered into the composition of many of the pharmaceutical preparations of the 17th and 18th centuries would astonish most of the practitioners and patients of the present day. In the earlier editions we find enumerated earthworms, snails, wood-lice, frogs, toads, puppy dogs, foxes ('a fat fox of middle age, if you can get such a one'), the skull of a man who had been hanged, the blood of the cat, the urine and excrements of various animals, &c.; and electuaries were ordered, containing 50, 62, and in one instance—Mathiolus, his Great Antidote against Poison and Pestilence—124 different ingredients.

The Edinburgh Pharmacopœia is more modern than the London, the first edition having appeared in 1699; while the Dublin Pharmacopœia does not date further back than 1807. The latest editions of these works appeared in the years 1841 and 1850 respectively.

Until the Medical Act passed in 1858, the right of publishing the pharmacopœias for England, Scotland, and Ireland was vested in the Colleges of Physicians of London, Edinburgh, and Dublin respectively; and as these three pharmacopœias contained many important preparations, similar in name but totally different in strength (as, for example, dilute hydrocyanic acid, solution of hydrochlorate of morphia, &c.), dangerous complications arose from a London prescription being made up in Edinburgh or Dublin, or *vice versâ*. By that act it is ordained that 'the General [Medical] Council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the General Council shall think fit, to be called *British Pharmacopœia;*' and by a subsequent act it is enacted that 'the British Pharmacopœia shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned pharmacopœias.' The *British Pharmacopœia*, which appeared in the beginning of the year 1864, gave rise to such a general feeling of disappointment throughout the profession that the General Council brought out a new and amended edition in 1867. A second reprint with additions appeared in 1874. Another edition was published in 1885, and a supplement to it in 1890. There are also Homœopathic and Veterinary Pharmacopœias, and Pharmacopœias for the London and other hospitals, but these are not printed by authority, nor authorised in any way by government.

The Pharmacopœia of the United States is drawn up by a national convention consisting of delegates from the various medical societies, medical corporations, and universities throughout the United States. It was first published in 1820, and a second edition appeared in 1828; but it is now revised every ten years, a new revision appearing in 1893.

Pharmacy, a department of the medical art which consists in the collecting, preparing, preserving, and dispensing of medicines. In Great Britain the practice of pharmacy is regulated by a

series of *Pharmacy Acts*, of which the more important are those of 1852, 1868, 1869, and 1882. See ADULTERATION, CHEMISTS AND DRUGGISTS, MEDICINE, PHARMACOPŒIA, PRESCRIPTION.

Pharos. See ALEXANDRIA, and LIGHTHOUSE.

Pharsa'lus, now FERSALA, a town of Thessaly, to the south of Larissa, on a branch of the Salambria, and accordingly in the part of Thessaly restored to Greece in 1881; hence the Greeks had to retreat in April 1897. The district, Pharsalia, is historically notable mainly for Cæsar's great victory over Pompey, August 9, 48 B.C. See LUCANUS.

Pharynx (Gr.) is the name of that part of the alimentary canal which lies behind the nose, mouth, and larynx. Its nature and functions are described in the article DIGESTION, where an illustration will also be found. In cases of Diphtheria (q.v.) the pharynx is usually the chief seat of the disease. It is liable to ordinary inflammation or *pharyngitis*—an affection characterised by pain, especially in swallowing, without redness in the fauces or change of voice. Sometimes it proceeds to suppuration, and abscesses are formed. See QUINSY, THROAT.

Phascogalé, a genus of marsupial quadrupeds allied to the Dasyures (q.v.), and containing, according to the most reliable estimate, thirteen species, all of which are arboreal and insectivorous; they are spread through the Papuan islands and Australia. The best-known form is perhaps the 'Tapoa Tafa' (*P. penicillata*), of the size and appearance of a rat, which commits depredations in the larders of Australian colonists, and is of the fiercest disposition when meddled with. This marsupial has a curious resemblance to the rodent genus Hapalotis, also found in Australia. It may be a case of 'mimicry' between some of the species.

Phascolomys. See WOMBAT.

Phases (Gr. *phasis*, 'appearance'), the different luminous appearances presented by the moon and several of the planets, sometimes the whole, a part, or none of the luminous surface being seen from the earth. See MOON, PLANETS.

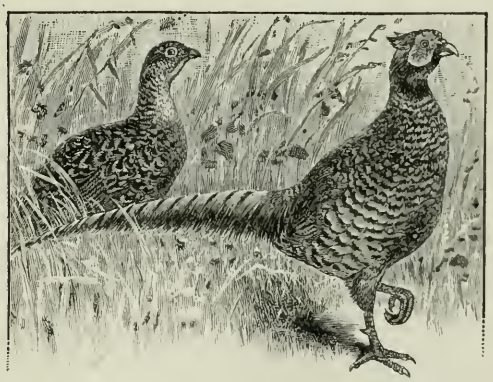
Phasianidæ. See PHEASANT.

Phasis, a river in Colchis, now called Rion or Faz. It rises in the Caucasus, and flows west into the Euxine near the ancient city of Phasis.

Phas'midæ (Gr. *phasma*, 'a spectre'), a family of insects, including walking-stick insects (Bacillus and Bacteria), spectre-insects (Phasma), and leaf-insects (Phyllium). With the exception of Bacillus, which occurs in south Europe, they occur in the tropics—in South America, Borneo, East Indies, &c. As their names suggest, they have a striking resemblance to the twigs and leaves of the plants on which they feed and live. See LEAF-INSECT, MIMICRY.

Pheasant (*Phasianus*), a genus of gallinaceous birds of the family Phasianidæ; having a rather short strong bill, a little curved; the cheeks and skin surrounding the eyes destitute of feathers, and warty; the wings short; the tail long, its feathers so placed as to slope down, roof-like, on either side, the middle feathers longest; the tarsus of the male furnished with a spur. The males of all the species are birds of splendid plumage; the females have shorter tails and dull or sombre colours. There are numerous species, natives of the warm and temperate parts of Asia. The Common Pheasant (*P. colchicus*) is said to have been brought from the banks of the Phasis, in Colchis, to the south of Europe at a very remote period, its introduction being ascribed in classic legend to the Argonauts. From the Phasis it derived its Greek name *Phasianos*, the origin of its name in English and other modern languages. It was soon naturalised in Europe, and is now diffused over almost all the temperate parts of it. The date of its introduction into Britain is not known, but was certainly earlier than 1199, when King John granted William Brewer a license 'to hunt the hare, fox, cat, and wolf, throughout all Devonshire, and to have free warren throughout all his own lands for hares, *pheasants*, and partridges' (Dugdale's *Baronage*, vol. i. p. 701). Strangely, however, the pheasant seems never to be mentioned as a royal dish till 1689. It has long been plentiful in plantations and game-preserves, and has been introduced into almost every part of the country suitable to its habits. The abundance of pheasants in Britain, however, is to be ascribed chiefly to careful game-preservation, without which the race would in all probability soon be extirpated. No kind of game falls so easy a prey to the poacher, for in its present method of rearing it is semi-domesticated, though we can hardly include it amongst our domestic fowls.

A minute description of the common pheasant is unnecessary. The feathers on the upper part of the head are brownish green, with edgings of yellow; the neck has variations of green and blue, with reddish orange below; the breast and sides are brownish yellow, each feather tipped with purplish blue; the back and belly are variegated, the rump deep red with green and grayish reflections; the tail is dull greenish yellow, with yellowish gray, and bars of black, and a band of dull red on each side. The whole length of a male pheasant is about 3 feet, of which the tail measures about 18 inches. The entire length of the female is a little more than 2 feet, principally in that the



Common Pheasant (*Phasianus colchicus*), male and female.

tail is much shorter than in the male. The general colour of the female is pale grayish brown and yellow, varied with darker brown, the sides of the neck tinged with red and green. The ordinary weight of a pheasant is about two pounds and a half; but when pheasants are abundantly supplied with food, and kept undisturbed, they are sometimes four pounds or four pounds and a half in weight. The pheasant, unlike the partridge, is polygamous.

The nest of the pheasant is on the ground, and is a rude heap of leaves and grasses, in which eleven or twelve olive-brown eggs are laid. But in the half-domesticated state in which it exists in many English preserves the pheasant does not pay that attention to its eggs and young which it does when more wild, and not unfrequently continues to lay eggs for a considerable time, like the domestic fowl; the eggs being removed by the gamekeeper, and hatched by hens, along with eggs from nests found

among clover and hay in the season of mowing. In fact, where pheasants are reared in large numbers nearly all the birds are hatched by either common hens or incubators, which are being largely employed for the purpose. In the former method coops are employed, in front of which are runs formed by wire netting, and in this way a large number can be attended to at one time. Very young pheasants must be carefully supplied with ants' eggs, maggots, gentles, &c., and the whole difficulty of rearing them is in their earliest stage. The difficulty of rearing birds bred in confinement has led to the introduction of various forms of artificial food, several of which are excellent. Custard is largely employed, and when given fresh is eaten with avidity, and brings on the young birds rapidly. Canary-seed is good also at first. Pheasants feed very indiscriminately on berries, seeds, roots, young shoots of plants, worms, insects, &c. Beans, peas, corn, and buckwheat are frequently thrown for them in open places in woods; and they scrape up bulbous and tuberous roots in winter. They roost in trees at no great height from the ground, and poachers sometimes capture them by burning sulphur below them. During the moulting season they do not ascend trees to roost, but spend the night on the ground, when they fall a ready prey to foxes. They are fond of woods with a thick undergrowth, in which, when disturbed, they naturally seek shelter, running whilst it is possible, rather than taking flight. The male pheasant takes flight much more readily than the female, which, apparently trusting to her brown colour to escape observation, often remains still until the sportsman is almost upon her. The males and females do not associate together except during the breeding season, but small numbers of one sex are often found in company. The 'short crow' of the males begins to be heard in March. In England and Scotland pheasant-shooting legally begins on the 1st of October, and ends on the 3d of February. The pheasants turned out from the gamekeeper's breeding-yard into a preserve are in general supplied with abundance of food during winter, and come to the accustomed call as readily as any kind of poultry, so that the sportsmanship of a *Battue* (q.v.), in which they are killed by scores or hundreds, is of the lowest kind. Maize is one of the best foods, but barley, peas, wheat, and oats, with the usual green food, are all employed. Some pheasant rearers use chopped meat, boiled potatoes, decayed apples, raisins, and similar dainties. It is scarcely necessary to mention that the flesh of the pheasant is in very high esteem for the table.

The female pheasant, as is the case with most other birds, in old age, or when from any cause incapable of the functions of reproduction, sometimes assumes the plumage of the male. The pheasant exhibits a remarkable readiness to hybridise with other gallinaceous birds. A hybrid between it and the common fowl is not unfrequent, and is called a *Pero*. Hybrids between the pheasant and black grouse have also occurred; and hybrids are supposed to have been produced between the pheasant and guinea-fowl, and the pheasant and turkey. None of these hybrids, however, have ever been known to be fertile, except with one of the original species. On the contrary, the offspring of the common pheasant and the Chinese or Ring-necked Pheasant (*P. torquatus*) is perfectly fertile, a circumstance which is urged in argument by those who regard them as mere varieties of one species. The ring-necked pheasant is now almost as plentiful in Britain as the common pheasant: it is a native of the forests of India and China, and is said not to breed with the common pheasant in a truly wild state, but in Britain they readily intermix. It is distinguished by a white ring almost surrounding the neck, and is of smaller size than the common pheasant, somewhat different in markings, and has a shorter tail. It is the common pheasant of the Celestial Empire. There is also the Ringless Chinese Pheasant (*P. decollatus*), and others scarcely known here. The Bohemian Pheasant is another variety of a creamy colour, and it is much more homely in appearance. White pheasants are of not very unfrequent occurrence, and often appear spontaneously from the common variety. Pied pheasants may be bred from crossing the white and common varieties. Of other species of pheasant may be mentioned Diard's Pheasant (*P. versicolor*), a native of Japan, in which the prevailing colour is brilliant green; Soemmering's Pheasant (*P. soemmeringii*), also from Japan, one of the most beautiful pheasants known, but terribly pugnacious; and Reeves's Pheasant (*P. reevesii*), a native of the north of China, in which white is the prevailing colour, and the tail is of extraordinary length, so that a bird not larger than the common pheasant measures eight feet in entire length. Of somewhat different type, and more nearly approaching to the common fowl, are the Golden Pheasant (*P. pictus*, or *Thaumalia picta*) and the Silver Pheasant (*P.* or *Euplocamus nycthemerus*), both natives of China, and hardy birds, the introduction of which into British preserves has been attempted with decided success. Both have long been kept in a state of domestication by the Chinese. The golden pheasant is one of the most splendid of the tribe. It has a fine crest, and a ruff of orange and black, capable of being erected at pleasure. The tail is very long. The crest and ruff are held in great estimation by anglers for making artificial flies. Lady Amherst's Pheasant (*P.* or *Thaumalia amherstiæ*) is a native of China, resembling the golden pheasant, and with an extremely long tail. The silver pheasant is one of the largest and most powerful of the tribe, and very combative, driving the common pheasant from preserves into which it is introduced. The prevailing colour of the upper parts and tail of the male is white, finely pencilled with black, the breast and belly purplish black. The Eared Pheasant (*Crossoptilon mantchuricum*) has a sombre brown body, a vaulted beak, red face, and white throat and ears, the feathers on which stand up above the head. The Argus Pheasant (*Argus giganteus*), found in Malacca and Siam, is separately discussed (see ARGUS). The latter series of pheasants are chiefly kept in aviaries as ornamental fowls, for which purpose they are well adapted. A recent introduction, the Prince of Wales Pheasant (*P. principalis*), was discovered on the Afghan frontier of India, and is distinguished from all other pheasants in that the greater part of its wings are white, though it is somewhat different in its markings and the arrangement of its colours.

See D. G. Elliot, *Phasianidæ* (1870–72), Tegetmeier, *Pheasants* (1873); Price, *Pheasant-rearing* (1888); Macpherson and others, *The Pheasant* (1895).

Phelps, ELIZABETH STUART, an American authoress, was born 31st August 1844, at Andover, Massachusetts, the daughter of Professor Austin Phelps and of the authoress of *Sunny Side*. Besides lecturing and engaging in work for the advancement of women and for social reforms, she has written a number of stories, including *The Gates Ajar* (1868), which passed through twenty editions in the year of its publication; *Beyond the Gates* (1883); *The Gates Between* (1887); *Hedged In* and *The Silent Partner* (1870); *The Story of Avis* (1877); *Doctor Zay* (1884), in which the question of professional life for women is considered; and in 1890, in conjunction with her husband, the Rev. Herbert D. Ward, *Come Forth*, a travesty of the story of Lazarus, and *The Master of the Magicians*.

Phelps, SAMUEL, the last of the old school of actors, was born 13th February 1804 in Devonport. When seventeen years old he came to London, and was engaged on the *Globe* and *Sun* newspapers as reader; among his companions being Douglas Jerrold, then, like himself, a stage-struck youth. After some experience as an amateur, Phelps joined the York circuit in the autumn of 1826, and continued in the provinces for eleven years. On 28th August 1837 he made his début in London as Shylock at the Haymarket, under the management of Benjamin Webster, making a very great success. He was afterwards engaged by Macready, but his genius did not get full scope until the beginning of his famous Sadler's Wells management, one of the most extraordinary achievements in the history of the drama. At an outlying unfashionable and unpopular theatre he for eighteen years produced a constant succession of 'legitimate' plays, attracting around him an excellent company, and educating a rough and unpolished audience to appreciation of the masterpieces of English dramatic literature. He began this apparently unpromising experiment on 27th May 1844, continued as manager till March 1862, and made his last appearance before his Islington friends on 6th November 1862. During his management he produced no fewer than thirty-one Shakespearian plays, as well as works of the other great Elizabethans, and of the dramatists of the 18th century from Congreve to Colman. After leaving Sadler's Wells Phelps did not attach himself to any particular theatre, appearing at Drury Lane, the Queen's, and the Gaiety theatres, and playing regularly in the provinces. On 1st March 1878, when acting Wolsey at the Aquarium (Imperial) Theatre, he broke down, and never played again. He died on 6th November 1878. Although primarily a tragedian, Phelps was an excellent all-round actor, and some of his comedy parts are among his most notable—as, for instance, Malvolio, Bottom, and Shallow. In tragedy he was famous in Wolsey, Lear, Macbeth, Brutus, Luke (*City Madam*), and Sir Giles Overreach; while among his other chief successes were Richelieu, Sir Pertinax Macsycophant, Bertuccio, Old Dornton, and Job Thornberry.

See *Memoirs*, by J. and E. Coleman (1886); and *Life and Life-work*, by W. May Phelps and John Forbes Robertson (1886).

Phenacetin, a drug prepared from carbolic acid, valuable in fevers, and, like antipyrin, of service in stilling pain and securing rest in cases of severe headaches, insomnia, and nervousness.

Phenacodus. See MAMMALS.

Phenol, a name for Carbolic Acid (q.v.). See also AROMATIC SERIES; and for the Phenol Dyes, DYEING, Vol. IV. p. 141.

Pheræ, a powerful city of Thessaly, near Mount Pelion; according to legend, the ancient royal seat of Admetus and Alcestis, and afterwards of political consequence under 'tyrants' of its own, who long made their influence felt in the affairs of Greece, and repeatedly attempted to make themselves masters of Thessaly. One of these tyrants, Alexander (slain 357 B.C.), is particularly celebrated for his cruelties.

Pherecydes, an ancient Greek philosopher, born in the island of Syros, in the 6th century B.C., a contemporary of Thales. He taught the doctrine of the existence of the human soul after death; but it is uncertain if he held the doctrine of the transmigration of souls, afterwards promulgated by his disciple, Pythagoras. Of his work, a mythological system of philosophy, only fragments are extant, collected and edited by Sturz (2d ed. Leip. 1824).—Another Pherecydes, a native of Leros, who lived in the 5th century B.C., compiled mythical histories of Athens and other states, but only a few fragments remain, published in C. Müller, *Frag. Hist. Græc.* (vol. i.).

Phi Beta Kappa, by far the oldest of the American college Greek letter societies, takes its name from the initial letters of its motto, said to be Φιλοσοφία Βίου Κυβερνήτης—'Philosophy is the guide of life.' The society, 'founded on literary principles,' and intended to embrace the 'wise and virtuous of every degree and of whatever country,' was an outcome of the desire for national union, and sprang into being in the somewhat chaotic period when the old colonies had became states, but had not yet adopted a federal constitution. It was founded in 1776 (the same year as the Illuminati, q.v.), in the old 'Raleigh Tavern' at Williamsburgh, Virginia, by forty-four undergraduates of William and Mary College, of whom John Marshall was one. Branches were established at Yale in 1780 and at Harvard in 1781; and to-day there are nearly a score in the principal colleges and universities of the Union. The Phi Beta Kappa is now simply 'an agreeable bond of meeting among graduates;' since 1831 its innocent mysteries have been open secrets. At Harvard there is an annual Phi Beta Kappa dinner, oration, and poem; the earliest and one of the most striking of Edward Everett's great orations was delivered before the society, with Lafayette for a guest, in 1824; and among the poets may be mentioned R. T. Paine ('The Ruling Passion,' which brought him $1200 on its publication in 1797) and Oliver Wendell Holmes (1829).—In colleges where the first third of a graduating class are admitted to Phi Beta Kappa there is a burlesque of the society, the Kappa Beta Phi, for the consolation of the third at the other end of the class, generally in the order of demerit, the winner of the Wooden Spoon (q.v.) ranking first. See an interesting paper by Dr E. E. Hale, in the *Atlantic Monthly* (July 1879).

Phidias (Gr. *Pheidias*), the greatest sculptor of ancient Greece, was born the son of Charmides, at Athens about 500 B.C. His instructor in sculpture was Ageladas of Argos. To Phidias came an opportunity such as falls to the lot of few artists: Pericles, having risen to the head of affairs in the Athenian state, resolved to adorn the city with temples and other public buildings fitting for the vanquisher of Persia, and he not only gave to Phidias a commission to execute the more splendid statues that were to be erected, but made him general superintendent of all the public works planned for the city. Plutarch tells us that Phidias had under him architects, statuaries, workers in copper and bronze, stonecutters, gold and ivory beaters, &c. He constructed the Propylæa and the Parthenon, the sculptured ornaments of which were executed under his direct superintendence, while the statue of the goddess Athena, of ivory and gold, was the work of Phidias himself. Fragments of the metopes, frieze, and pediments of the Parthenon were carried to England by Lord Elgin (see ELGIN MARBLES). Phidias executed a colossal statue of Zeus for the Olympieum at Olympia (q.v.), also of ivory and gold; this was reckoned his masterpiece. Accused of having appropriated to himself some portion of the gold destined for the robe of Athena, and of impiety in having introduced his own likeness and that of Pericles on the shield of the goddess, he was thrown into prison, and died there about 432 B.C., but whether of sickness or poison is uncertain. Other works by his hand were a statue of Aphrodite at Elis, of gold and ivory, a colossal bronze figure of Athena Promachos on the Acropolis at Athens, a gilt colossal Athena at Platæa, a monument of the victory of Marathon at Delphi,

and numerous others. Their prevailing characteristic appears to have been an ideal sublimity, and even the imperfect relics that we possess are the most noble specimens of sculpture in the world. In 1888 there was dug out at Tanagra a red vase bearing what was believed to be the signature of Phidias. See SCULPTURE.

See A. S. Murray, *Greek Sculpture* (1880); C. Waldstein, *Essays on the Art of Phidias* (Camb. 1885); and Collignon, *Phidias* (Paris, 1886).

Phigalia, an ancient town of Arcadia, situated in its extreme south-west corner. From its temple of Apollo, at Bassæ, 5 to 6 miles distant, a sculptured frieze representing the contests between the Centaurs and Lapithæ, and the Amazons and Greeks, was brought to the British Museum in 1812. The temple was first described by Chandler in 1765. Next to the Theseum at Athens it is the most perfect architectural ruin in all Greece, being built of fine gray limestone and white marble. It was designed by Ictinus, one of the architects of the Parthenon at Athens, and measured originally 125½ feet long and 48 broad, and had 15 columns on each side and 6 at each end, in all 38, of which 34 still stand. See Cockerell, *Temples of Ægina and Bassæ* (1860).

Philabeg. See HIGHLAND COSTUME.

Philadelphia, the chief city of Pennsylvania and the third city of the United States, is situated on the Delaware River, about 100 miles by ship-channel (*viâ* Delaware Bay and River) from the Atlantic Ocean, 90 miles by rail SW. of New York City and 136 miles NE. of Washington. Co-extensive with the county of Philadelphia, the city lies along the Delaware from the mouth of the Schuylkill River at League Island, northward, for about 15 miles, and has an average breadth of some 8 miles. Its total area embraces nearly 130 sq. m., about one-eighth of which is comprised within the limits of the thickly built up portions of the city, while the rural sections consist of towns and villages which, though within the city limits, are locally known by the names they bore prior to their annexation to the city. Philadelphia is notably 'a city of homes.' Its inhabitants are largely composed of the well-to-do middle class, and it has within its limits more comfortable single residences than any other city in the world.

Copyright 1891 in U.S. by J. B. Lippincott Company.

The dominant architecture of the older sections of the city is of the severely plain, substantial style which characterised its Quaker founders, and which until the second half of the 19th century held undisputed sway, its outstanding features being uniformity of design and a general employment of red brick as building material. A marked departure has, however, lately taken place in the style of both the public and the private buildings of Philadelphia, among the former of which the city hall (1871 *et seq.*), built of white marble upon a granite base, and covering an area of 486 by 470 feet, affords a striking instance. The height of the tower and dome is 537 ft. 4½ in.; or 573 ft. 4½ in. with the colossal figure of Penn (36 ft.), to surmount the whole, the structure being thus the second highest in the world. Over 500 rooms (mostly offices for city officials) are comprised in this edifice, and more than $14,000,000 had by 1891 been expended upon it; the entire cost, when completely furnished for occupancy, is estimated at $20,000,000. Other buildings worthy of note architecturally are the Masonic Temple, of granite, erected at a cost of over $1,500,000; a United States government building of granite—containing the Post-office, United States court-rooms, and other offices of the general government—which cost about $8,000,000; a custom-house of marble, modelled after the Parthenon at Athens; a naval asylum; the United States Mint; the Academy of Fine Arts; the Academy of Natural Science, a massive Gothic structure with an extensive scientific library and a museum of a million or more specimens; the Academy of Music; and the buildings of the University of Pennsylvania.

Nearly every street of importance is traversed by tramways, either horse, steam, cable, or electric. There are numerous well-shaded commons in the older portion of the city, some of which were laid out by William Penn at the foundation of his 'great towne' in 1682–83; while the Fairmount Park, some 3000 acres in extent, and bisected through its entire length of 10 miles or more by the Schuylkill River and its affluent the Wissahickon, stands without a rival among the pleasure-grounds of the great cities of the New World. In this park in 1876 was held the Centennial Exhibition; and in its environs are the Zoological Garden, the Fairmount Waterworks, which supply to the city 100,000,000 gallons of water daily, the beautiful Horticultural Hall and Memorial Hall—remains of the Centennial Exhibition—the Laurel Hill Cemetery, &c. Among the statues in Philadelphia there are bronze equestrian figures of Generals Meade, McClellan, and Reynolds; and there is a monument at Germantown to the Union soldiers, and another in the grounds of Girard College to those of its former pupils who fell in the civil war.

The churches include the old Swedes Church (1700), Christ Church (Episcopal, 1727–54), where Washington's pew is preserved, and a Roman Catholic cathedral. There are some 75 Baptist churches in the city, 90 Episcopal, 40 Lutheran, 100 Methodist, 100 Presbyterian, 15 Quaker, 60 Roman Catholic, and a number of others. Philadelphia has almost from its foundation been noted for its benevolent institutions, but these have been greatly increased within recent years: prominent among such institutions are the Pennsylvania Hospital (1751), with suburban departments for the insane; Episcopal, Presbyterian, and Methodist hospitals, and the St Joseph's and St Agnes' hospitals; the hospitals in connection with the university and the several medical schools, &c.

The educational facilities of Philadelphia are very great. At the public schools, which are maintained at an annual cost of $2,600,000, there are 2700 teachers and 130,000 pupils, some 2000 of the latter belonging to the high and normal schools. In the Roman Catholic schools 30,000 children are enrolled. Besides the Girard (q.v.) College, the city contains the Drexel Industrial Institute (endowed with $2,000,000) and the Cahill Roman Catholic High School; and in Philadelphia or its immediate environs are the Williamson Free School of Mechanical Trades (endowed with some $2,200,000), state institutions for the blind and deaf and dumb, the Franklin Institute (1824, for the mechanic arts), Spring Garden Institute (for drawing, painting, and mechanical handiwork), the Episcopal Academy (1785), several Catholic colleges and convents, and Episcopal, Lutheran, and Roman Catholic theological seminaries. Crowning all these is the University of Pennsylvania, which began as an academy chartered by the sons of William Penn, became a college in 1755, and a university in 1779. At present it has over 1600 students and 75 professors and instructors, and embraces faculties of arts, science, architecture, natural history, and finance and economy (475 students), of medicine (680), dentistry (200), veterinary medicine (70), law (175), and physical education. The Jefferson Medical College (1825), with nearly 600 students, is one of the most famous medical schools of the United States; and others here are the Hahnemann

Medical College (1869), the Medico-Chirurgical College (1880), the Woman's Medical College (1850), and the Philadelphia Polyclinic and College for Graduates in Medicine.

Manufactures, Commerce, &c.—Though in its early history noted for its extensive shipping interests, as compared with those of its sister cities, it is rather as a manufacturing than as a commercial city that Philadelphia holds a present prominence. Here are immense establishments covering acres of ground, from which millions of dollars worth of products are issued annually for the home and foreign markets, besides smaller concerns innumerable. The aggregate capital employed in manufacturing is estimated at $300,000,000, the number of hands employed at 250,000, and the value of the annual product at $600,000,000. Among the prominent industries of this class are the building of locomotives, of which $10,000,000 worth are constructed annually, employing some 5000 men; the manufacture of carpets, at which about 30,000 hands are employed, producing annually goods valued at about $50,000,000; woollen and worsted goods, employing 35,000 hands, and valued at $45,000,000; upholstery goods, valued at $25,000,000; cotton goods, $15,000,000, &c. General iron and steel products are computed to employ 40,000 hands, whose product reaches $75,000,000 in value—the single article of saws, principally made by one firm, giving employment to 5000 workmen, and amounting in value to $2,500,000. There are several extensive sugar-refineries, the out-put of which reaches 20,000 barrels of refined sugar daily, and gives direct employment to 2500 hands; oil-refineries, whose receipts of crude petroleum by railways and pipelines from the oil-fields of western Pennsylvania reach 6,000,000 barrels per annum; nearly 100 breweries; and several great chemical works.

The value of the exports for the fiscal year 1869–70 was $16,927,610; for 1879–80, $49,649,693; for 1889–90, $37,410,683. The imports for 1869–70 were valued at $14,483,211; for 1879–80, $35,944,500; for 1889–90, $53,936,317. In 1897 the total value of the foreign trade of Philadelphia was $95,406,642, including exports and imports; in the same year 5906 vessels entered and 5904 cleared the port.

Eminent Philadelphians have been: Kane the explorer; General McClellan; Dr Morton, of anæsthetic fame; the actors Edwin Forrest, Joseph Jefferson, and Hermann Vezin; Henry George; Charles Hodge; C. G. Leland; Kate Wiggin; and Frank Stockton.

The city government is almost entirely administered by the mayor through various departments—of public works and of public safety, each administered by a director who is appointed by him; of receiver of taxes, of city treasurer, of city controller, and of law, whose heads are elected for three years; a department of education governed by a board of 35 members (one from each city ward), who are appointed by the judges of the courts, and who serve without compensation; a department of charities and correction, whose officials are appointed by the mayor, and who serve without compensation; and a sinking fund commission. The legislative branch of the city government consists of a chamber of select council of thirty-five members (one from each ward) who are elected for three years, and a chamber of common council of 117 members who are elected for two years, all of whom serve without pay. The judiciary of the city and county consists of twelve judges of the Courts of Common Pleas and four judges of the Orphans' Court, all of whom are elected for ten years. There are besides twenty-eight magistrates elected for five years.

Founded in 1682 (see PENN), Philadelphia the year after was made the capital of Pennsylvania, and soon became a place of importance. It was the central point in the war of independence, and the city still preserves the Carpenters' Hall (1770), where the first congress met (4th September 1774), and the old State House (1735), with its Liberty Bell, where the Declaration of Independence (see INDEPENDENCE DAY) was adopted in 1776, and which has since been famous as Independence Hall. At Philadelphia, moreover, the federal union was signed, in 1778; and here, too, the constitution was framed, in 1787. An interest of another kind attaches to the fact that the Protestant Episcopal Church of North America was organised here in 1786. From 1790 to 1800 Philadelphia was the federal capital; and the first mint was established here in 1792. Later events have been the holding of the Centennial Exhibition, in 1876, and the commemoration of Penn's visit, in 1882. Pop. (1700) 4500; (1800) 70,287; (1860) 568,034; (1880) 847,170; (1890) 1,046,964.

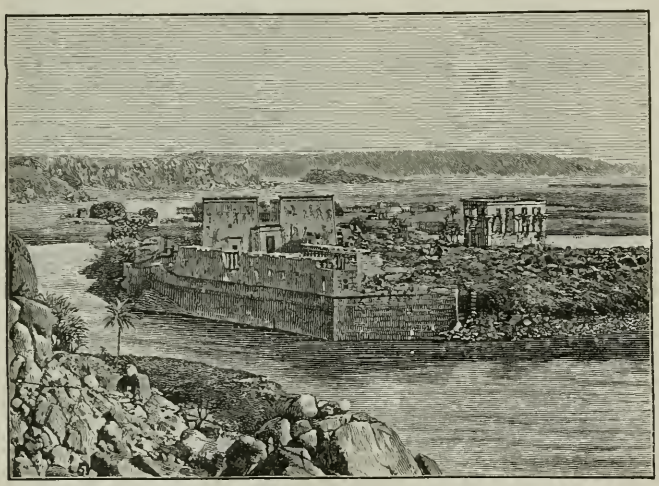
Philadelphia, in Asia Minor. See ALA-SHEHR.

Philadelphians, a mystic sect emphasising 'brotherly love' (Gr. *philadelphia*), founded in London in 1652 under the influence of Boehme by Dr John Pordage (1608–98) and Mrs Leade and others. It had for a time a branch in Holland, but disappeared early in the 18th century.

Philæ (Gr. *Philai*, Egyptian *Pālek*), an island in the Nile, near Assouan and south of Syene, in Nubia. It is a small granite rock, fringed with rich verdure, about 1200 feet long and 450 broad, almost covered with ancient buildings of great architectural beauty and interest, though not of very ancient date. That to the east, a hypæthral or roofless hall, commonly called 'Pharaoh's bed,' belongs to the Greek and Roman period, and consists of fourteen great columns with capitals of various patterns, connected at the lower part by solid walls; the length is 63 feet, the width 48. The great temple of Isis, to whom the island was sacred, was mainly built by Ptolemy Epiphanes, and continued by his successors, especially by Ptolemy III., Euergetes. The processions of pilgrims approached the island from the south, were received by the priests at a flight of steps at



Island of Philæ, seen from the south-west corner.

the south-west corner, and then passed into a court with a colonnade to right and left, erected by Tiberius and later Roman emperors. To the north stood the great propylon or gateway, 60 feet high and over 120 wide. This is the oldest part of the temple, and bears the name of Nectanebes II. (about 361 B.C.). Beyond was another court with several chambers and a small chapel. Another smaller pylon gave entrance to the temple proper, at the northern extremity of the irregular complex of buildings. The temple proper was converted into a Christian church in 577. The plan for a great irrigation dam here, adopted in 1898, does not submerge or injure the ruins.

Philaret (1782–1867), became in 1817 Bishop of Reval, in 1819 Archbishop of Tver, and in 1821 Archbishop of Moscow. He was the greatest preacher and the most influential Russian churchman of his time.

Philately. See STAMPS.

Philemon, EPISTLE TO, is the shortest of the four extant letters that bear to have been written by the apostle Paul during his captivity (see PAUL). It is a brief private letter (of twenty-five verses) addressed to Philemon, a man of wealth and liberality, who had been a convert of the apostle, and is now addressed by him as his 'fellow-worker.' It was at Philemon's house, and perhaps under his presidency, that the Christians of Colossæ held their meetings. In the *Apostolical Constitutions* he is represented as bishop of Colossæ, and subsequent tradition has it that he suffered martyrdom there under Nero. Philemon had possessed a slave called Onesimus, who, after robbing his master, had run off and found his way to Rome (or Cæsarea), and there had come under the influence of Paul, and been converted to Christianity. At first the apostle seems to have been minded to retain Onesimus for his own service, but on further consideration he resolved to send him back to his former master, and accordingly made him the bearer of the epistle before us, in which 'Paul the aged' asks pardon for the runaway, and entreats the injured master to receive him 'not now as a servant, but above a servant, a brother beloved.' The epistle exhibits fine delicacy and tact throughout, and has been characterised by Renan as 'a little masterpiece in the art of letter-writing.' Its genuineness may be said to be well established. Some writers, indeed, in the fourth century held that it was too trifling and unedifying to have been written by Paul; but the arbitrariness of this criterion was pointed out by Jerome, Chrysostom, and others. Baur also regarded it as a literary invention intended to illustrate the ideal relation of master and slave; but this view is not strongly urged by any of his modern followers, while some of them (Hilgenfeld and Holtzmann) have entirely abandoned it. There are commentaries on the Epistle to Philemon by Meyer, Bleek, Ellicott (*Philippians, Colossians, and Philemon*, 3d ed. 1865), and Lightfoot (*Colossians and Philemon*, 7th ed. 1884).

Philemon and Baucis, according to a classic myth, finely poetised by Ovid in his *Metamorphoses*, were a married pair, remarkable for their mutual love. Jupiter and Mercury, wandering through Phrygia in human form, were refused hospitality by every one, till this aged pair took them in, washed their feet, and gave them such humble fare as they could provide. On going away, the gods took them with them to a neighbouring mountain, on looking from which they saw their village covered with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple, and that they might die at the same time. When, accordingly, they were seated at the door of the temple, being now of great age, they were changed, Philemon into an oak, and Baucis into a linden.

Philharmonic Society, established in London in 1813, welcomed Mendelssohn to England in 1829 and again in 1844. The New Philharmonic was founded in 1852. The Philharmonic Society of New York dates from 1842.

Philidor, the assumed name of a French family, originally called Danigan, which has produced several distinguished musicians, and a composer, François André (born at Dreux in 1726, died in London, 1795), who was even more famous as an authority on Chess (q.v.). See Allen's *Life of Philidor* (Phila. 1864).

Philip of Macedon, the father of Alexander the Great, was born at Pella in 382 B.C. He was the youngest son of Amyntas II. and Eurydice, and spent part of his early life as a hostage at Thebes. The assassination of his eldest brother, Alexander II. (367 B.C.), and the death of his second brother, Perdiccas III., in battle (360 B.C.), made him guardian to his nephew Amyntas, still an infant; but in a few months Philip made himself king, the rights of Amyntas being set aside. Dangers soon beset him from without and from within. But foreign and domestic enemies soon disappeared before the decision, the energy, and the wise policy of the young king. In the brief space of a year he had secured the safety of his kingdom, and had gained for himself a dreaded name. Henceforward his policy was one of aggression. The Greek towns on the coast of Macedonia were the first objects of attack. In Thrace he captured the small town of Crenides, which under its new name, Philippi, soon acquired great wealth and fame. The surrounding district was rich in gold-mines, which proved a source of great revenue to Philip, and supplied him plentifully with the means of paying his armies, and of bribing traitorous Greeks to open the gates of many cities. After a few years of comparative leisure he captured Methone (at the siege of which he lost an eye), advanced into Thessaly, and ultimately to the Pass of Thermopylæ, which, however, he did not attempt to force, as it was strongly guarded by the Athenians. He therefore directed his arms against the Thracians. After capturing all the towns of Chalcidice—the last of which was the important city of Olynthus—he made peace with the Thracians, and next year with the Athenians, who had been at war with him in defence of their allies the Olynthians. It was this siege of Olynthus by Philip which called forth the famous Olynthiac orations of Demosthenes. Philip was now requested by the Thebans to interfere in the war ('the Sacred War') which was raging between them and the Phocians. He marched into Phocis, destroyed its cities, and sent as colonists to Thrace many of the inhabitants (346 B.C.); and he was appointed, jointly with the Thebans and Thessalians, as president of the Pythian games. His next step was to secure a footing in the Peloponnese, by espousing the cause of the Argives, Messenians, and others against the Spartans. In 339 B.C. the Amphictyonic Council declared war against the Locrians of Amphissa; and, in the following year, appointed Philip commander-in-chief of their forces. The Athenians were alarmed at his approach into Greece in this capacity, and formed a league with the Thebans against him; but their united army was utterly defeated at the battle of Chæronea (338 B.C.), and all Greece was at the feet of the conqueror. He was now in a position to enter on the great dream of his later years—viz. to invade the Persian empire, and revenge the injuries of Greece. Deputies from the different states of Greece assembled in congress at Corinth, and, after resolving to make war on the Persian king, chose Philip as leader of their armies. Preparations were in progress for this great expedition when he was suddenly cut off by the hand of the assassin Pausanias, at a festival to celebrate the marriage of his daughter with Alexander of Epirus (336 B.C.). Philip was a man given to self-indulgence and sensuality; he was faithless in the observance of treaty obligations, and unscrupulous as to the means by which he gained his ends; but of his energy, acuteness, and eloquence it is impossible to speak too highly. He was at the same time a lover of learning and a liberal patron of learned men. See works cited at GREECE and DEMOSTHENES.

372

Philip II., better known as PHILIP-AUGUSTUS, king of France, was the son of Louis VII. and Alix of Champagne, and was born in August 1165. He was crowned joint-king in 1179, during the lifetime of his father, succeeded him in 1180, and proved one of the greatest monarchs of the Capet dynasty, while he confirmed his hold of the throne by marriage with Isabella of Hainault, the last direct descendant of the Carlovingians. His first war, made upon the Count of Flanders, gave him the county of Vermandois and the city of Amiens. He rigorously punished heretics and despoiled the Jews, and reduced the rebellious Duke of Burgundy to submission. He supported the sons of Henry II. of England in their rebellions against their father, and gained Berri by cession in 1189. On the accession of Richard to the throne Philip and he set out together on the third crusade; but they quarrelled while wintering in Sicily. After staying but three months in Syria he returned to France, having taken a solemn oath not to molest Richard's dominions; but no sooner had he returned than he made a bargain with the faithless coward John for the partition of Richard's territories in France. The fiery Richard's sudden return occasioned an exhausting war, which was closed through the mediation of Pope Innocent early in 1199. Richard died within two months after; but war with England blazed out anew, on account of the rival claims of John and his nephew Arthur of Brittany to the French heritage of King Richard, which consisted chiefly of Anjou, Maine, and Touraine. Philip embraced the cause of Arthur, but was for a while fully occupied by his quarrel with the pope. He had put away his second wife, Ingeborg of Denmark, in order to marry the beautiful Agnes of Meran, but the terror of the thunders of the Vatican forced him to replace Ingeborg upon her throne. The murder of Arthur again gave him the excuse he sought. Richard's great fortress of Château Gaillard fell early in 1204, and Philip passed in triumph over Normandy. Before the end of that year he had added to his dominions Normandy, Maine, Anjou, and Touraine, with part of Poitou, as well as the over-lordship of Brittany, hitherto a fief of Normandy. Philip took no active part in the war against the Albigenses, but devoted himself to consolidating his dominions. The great victory of Bouvines (29th August 1214) over the Flemish, the English, and the Emperor Otho established his throne securely, and the rest of his reign he was able to devote to reforms of justice and to the building and fortifying of the city of Paris. Notre Dame and the great court of peers remained lasting monuments of this great king's administration. He died at Mantes, July 14, 1223.

See works by Capefigue (3d ed. 2 vols. Paris, 1842), Mazabran (Lille, 1878), and Davidsohn (Stuttgart, 1888).

Philip IV., surnamed *Le Bel* or 'the Fair,' king of France, the son of Philip III., 'the Rash,' and Isabella of Aragon, was born at Fontainebleau in 1268, and succeeded his father in 1285. By his marriage with Queen Joanna of Navarre (q.v.) he obtained Navarre, Champagne, and Brie. He overran Flanders, but a Flemish revolt broke out at Bruges, and at Courtrai on the 'Day of Spurs' the flower of the French chivalry went down in thousands before the sturdy burghers. The great event of his reign was his struggle with Pope Boniface VIII., which grew out of his attempt to levy taxes from the clergy. By the bull *Clericis laicos* in 1296 Boniface forbade the clergy to pay taxes, and to this Philip replied by forbidding the export of money or valuables, thus cutting off a main supply of papal revenue. A temporary reconciliation in 1297 was ended by a fresh outbreak of the quarrel in 1300. Philip flung

the papal legate into prison, and summoned the three Estates of France, clergy, nobles, and burghers. The last two assured him of their support even in case of excommunication and interdict. Boniface replied with the celebrated bull *Unam Sanctam*. Philip caused the bull to be publicly burned, and with the consent of the States-general confiscated the property of those prelates who had sided with the pope. Boniface now excommunicated him, and threatened to lay the kingdom under interdict, but the king sent to Rome William de Nogaret, who seized and imprisoned the pope, with the aid of the Colonnas. Though released after a few days by a popular rising, Boniface soon afterwards died. In 1305 Philip obtained the elevation of one of his own creatures to the papal chair as Clement V., and placed him at Avignon, the beginning of the seventy years' 'captivity.' He compelled the unhappy and reluctant pope to condemn the Templars in 1310, and to decree the abolition of the order in 1312. In spite of skilful defence, they were condemned and burned by scores (see TEMPLARS), and their wealth appropriated by Philip. The grand-master, Jacques de Molay, was burned 18th March 1314, and at the stake he summoned Philip to compear within a year and a day, and the pope within forty days, before the judgment-seat of God; strange to say, both pope and king died within the time, the latter at Fontainebleau, November 29, 1314. Philip during his whole reign steadily strove for the suppression of feudalism and the introduction of the Roman law; but while thus increasing the power of the crown, and also that of the third estate, he converted royalty, which was formerly protecting, kind, and popular to the mass of the people, into a hard, avaricious, and pitiless taskmaster. Under him the taxes were greatly increased, the Jews persecuted, and their property confiscated; and, when these means were insufficient to satisfy his avarice, he caused the coinage to be greatly debased.

Philip VI., OF VALOIS, king of France, was the son of Charles of Valois, younger brother of Philip IV., and succeeded to the regency of France on the death of Charles IV. The proclamation of a king was deferred on account of the pregnancy of Charles IV.'s widow; but on her giving birth to a daughter Philip caused himself to be crowned king at Rheims (May 29, 1328). His right to the throne was denied by Edward III. of England, the grandson of Philip IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and therefore insisted upon the superiority of his own claims. Philip, however, was not only already crowned king, but he had the support of the people. His reign commenced gloriously; for, marching into Flanders to support the count against his rebellious subjects, he wiped out the disgrace of Courtrai by vanquishing the Flemings at Cassel (August 23, 1328). He was obliged to give up Navarre (q.v.), as the Salic law of succession did not apply to it, but he retained Champagne and Brie, paying for them a considerable annual stipend. The hundred years' war with England began in 1337 both in Guienne and in Flanders, but was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Sluys (June 24, 1340). Philip was a bad and faithless man, and his grasping extortion well-nigh exhausted the wealth of the country. Yet money for his pleasures and for new wars had constantly to be provided by some new tax or fresh confiscation. In 1346 Edward III. landed in Normandy, ravaged the whole country to the environs of Paris, and totally defeated Philip at Crécy. A truce was then concluded, but the devoted kingdom had no sooner been released from war than destruction threatened in the yet more terrible form of the 'Black Death.' Philip received Dauphiné in gift in 1349, purchased Majorca from its unfortunate king, and died August 22, 1350, neither loved nor respected.

Philip II., king of Spain, the only son of the Emperor Charles V. and Isabella of Portugal, was born at Valladolid, 21st May 1527. He was brought up in Spain, and carefully educated for his destiny, but grew up distrustful and reserved; cold and austere, without being virtuous; haughty and bigoted, yet without real respect for honour or religion. In 1543 he married Mary of Portugal, who died three years later, after bearing a son, the ill-fated Don Carlos. In 1548 he went to join his father at Brussels, and made a decidedly unfavourable impression upon his future subjects. Three years later he returned to Spain, and in 1554 he made a marriage of policy with Mary Tudor, Queen of England. During his fourteen months' stay in England he laboured hard but unsuccessfully at the uncongenial task of ingratiating himself with his wife's subjects. His failure, together with the vexatious jealousy of a wife who was plain, spare, nearly forty, and likely to be childless, prompted him to leave England and return to Brussels (September 1555). In the next half-year he became by the abdication of his father the most powerful prince in Europe, having under his sway Spain, the Two Sicilies, the Milanese, the Low Countries, Franche Comté, Mexico, and Peru; with the best disciplined and officered army of the age. The treasury alone was deficient, having been drained by the enormous expenditure of his father's wars. The first danger he had to face was a league formed between Henry II. of France and the Neapolitan pope Paul IV. to deprive him of his Italian dominions. Alva soon overran the territories of the pope, while Philip's army under Philibert of Savoy defeated the French at St Quentin (August 10, 1557) and Gravelines (July 13, 1558). These reverses forced Henry II. to agree to terms of peace at Cateau Cambrésis (April 2, 1559). In January 1558 the French had captured Calais, and Mary Tudor's death followed eleven months later. Her husband, after an unsuccessful attempt to obtain the hand of Queen Elizabeth, married Isabella of France (June 24, 1559) and returned to Spain, where he lived the rest of his life.

The main object of his domestic policy was to concentrate all power in himself, and to this end he laboured to destroy everything resembling free institutions in any of his dominions. He ostentatiously put himself at the head of the Catholic party in Europe, but the interests of the church in his eyes were ever identical with his own. He found the Inquisition the best engine of his tyranny in Spain, but its effect in the Low Countries was a formidable revolt, which ended in 1579 with the northern part, the Seven United Provinces, achieving independence. In this conflict the resources of Spain were exhausted, and to replenish his treasury Philip exacted enormous contributions from his subjects, abolishing all the ancient special communal or provincial privileges of Spain, and suppressing all insurrection and discontent by force of arms or the Inquisition. His son, Don Carlos, whom he hated, died in prison in 1568, and all that can be said in the father's justification is that at least he did not directly murder him. His pride did not disdain the aid of cowardly murder in the pursuit of his policy, and the tragic death of William the Silent (1584) and the relentless persecution of Antonio Perez show how pitiless and how persistent was his hatred of an enemy. He married in 1570 as his fourth wife his niece, Anne of Austria, whose sole surviving son afterwards became Philip III.

The one great triumph of his reign was the famous naval victory of Lepanto (September 16,1571), won by his half-brother, Don John of Austria, over the Turks. In 1580, the direct male line of Portugal having become extinct, Philip laid claim to the throne, and despatched Alva to occupy the kingdom. But his attempt to conquer England recoiled upon himself in hopeless disaster, as the ships of the great Armada were swept to destruction before the northern tempests and the irresistible valour of the English seamen. His intrigues against Henry of Navarre were foiled by his antagonist's courage, aided by the death (1592) of his own general Alexander Farnese and Henry's politic change of his religion. The stubborn heroism of the Netherlanders and the exasperating ravages of the English cruisers on the Spanish Main, added to financial distress at home, embittered the last years of Philip, and he died of a lingering and peculiarly loathsome disease, in the Escorial at Madrid, on 13th September 1598, under the shadow of that failure which had followed all his greatest undertakings. Philip II. possessed great abilities, but little political wisdom, and he engaged in so many vast enterprises at once as to overtask his resources without leading to any profitable result. A fanatical and gloomy bigot in religion, sullen and jealous in temper, he persecuted all heretics through the Inquisition with relentless cruelty, and at the same time dealt a fatal blow to Spain by crushing that ancient, proud, and chivalrous spirit which had been the secret of its strength, as well as by cutting off the commerce of the country by oppressive exactions and by a bitter persecution of the industrious Moriscos. There is hardly a more unlovable figure in history than this sullen and solitary bigot whom historians with unusual unanimity have united to condemn.

See the articles ALVA, ARMADA, CHARLES V., CARLOS, MARY, HOLLAND, and SPAIN; the *Histories* of Prescott, Motley, and Froude; Mignet's *Antonio Perez et Philippe II.* (5th ed. 1881); Forneron's *Histoire de Philippe II.* (3d ed. 4 vols. 1887); Gachard's two books on Don Carlos, and his editions of the correspondence of Philip (1848-89). The many good points of Philip's character are brought out in Froude's *Spanish Story of the Armada* (1892) and Martin Hume's monograph on Philip (1897).

Philip V., king of Spain, and the founder of the Bourbon dynasty in that country, was the second son of the Dauphin Louis (son of Louis XIV. and Maria Theresa of Spain) of France, and was born at Versailles, December 19, 1683. In 1700 Philip, then Duke of Anjou, was bequeathed the crown of Spain by Charles II. His grandfather, Louis XIV., as he left him to take possession of the throne, uttered the famous phrase, 'Mon fils, il n'y a plus de Pyrénées.' He entered Madrid in February 1701, and after a long and varying struggle against his rival, the Archduke Charles, was left in possession of his throne by the peace of Utrecht in 1713. Next year died the queen, Maria Louisa, daughter of Victor Amadeus, Duke of Savoy, whom Philip had married in 1702; and soon after he married Elizabeth Farnese of Parma, 'the termagant,' in Carlyle's phrase, who embroiled the peace of Europe for thirty years. By her influence the reins of government were committed by the amiable and weak-minded king to Alberoni. Philip was obliged by the Quadruple Alliance to dismiss his daring and ambitious minister at the close of 1719. He abdicated in favour of his son Don Louis in 1724, but resumed the crown on his death eight months later. The ambitious queen's dearest wish was to drive the Hapsburgs out of Italy in the interests of her sons by a former marriage, but all her efforts succeeded only in securing the Two Sicilies for Don Carlos. Spain joined the coalition against Maria Theresa, and her younger son Don Philip was at first successful in conquering the Milanese; but as soon as the Silesian war was closed by the treaty of Dresden the Austrian queen poured her troops into Italy and drove out the Spaniards. At the crisis Philip, who had been for years sunk in a state of mental stupor, died at Madrid, July 9, 1746. See ALBERONI, SUCCESSION (WARS OF), and SPAIN; and Baudrillart's *Philippe V. et la Cour de France, 1700–15* (2 vols. 1890–91).

Philip, sachem of the Wampanoag tribe of Indians, was the second son of Massasoit, who for nearly forty years had been the first and staunchest ally of the Pilgrim settlers of Plymouth, and had obtained English names for his two sons. In 1661 Philip succeeded his brother, and formally renewed the treaties of his father, which he kept for some years. By 1671, however, goaded by the encroachments of the whites, he had formed a confederation of tribes aggregating nearly 10,000 warriors; and in 1675 what is known as King Philip's War broke out. On the Indian side it was a war of surprises and massacres—thirteen towns were destroyed, and 600 colonists slain. In December 1675 Governor Winslow and a force of 1000 men burned the great fort of the Narragansetts, slew 600 warriors, and massacred 1000 women and children. In the spring the Indians retaliated for a time, but their numbers steadily diminished; several tribes fell away from the confederation; others, hitherto neutral, declared against them. In the early summer Philip's squaw and little son were captured, and sold as slaves for the West Indies; and on 12th August 1676, at midnight, he and his remaining followers were surprised by Captain Benjamin Church. Philip was slain, and his head cut off. Afterwards his body was drawn and quartered, and the head was exposed on a gibbet at Plymouth for twenty years. Church wrote an *Entertaining History of King Philip's War* (1716; new ed. with additions by S. G. Drake, Boston, 1825); see also Washington Irving's *Sketch-book*.

Philip the Bold (*Philippe le Hardi*), the founder of the second and last ducal House of Burgundy, was the fourth son of John the Good, king of France, and his wife Bonne of Luxemburg, and was born January 15, 1342. He was present at the battle of Poitiers (1356), and displayed such heroic courage, venturing his own life to save his father's, as earned him the epithet of *le Hardi*, or 'the Bold.' He shared his father's captivity in England, and on returning to France in 1360 received in reward of his bravery the duchy of Touraine, and on the death, without heirs, of Philippe de Rouvre (1363) also that of Burgundy, being created at the same time the premier peer of France. On the accession of his brother, Charles V., to the throne of France Philip had to resign Touraine, but, as a compensation, obtained in marriage Margaret, the heiress of Flanders, in 1369. In 1372 he commanded with success against the English, and in 1380 he helped to suppress the sedition of the Flemish towns against their count, his father-in-law. But the citizens of some of the populous places, especially Ghent, were possessed with such a fever of independence that they were only brought back to their allegiance after the bloody defeat of Rosbeck (November 27, 1382), where 26,000 Flemings were left on the field. Flanders, the county of Burgundy, Artois, Rethel, and Nevers fell to him by the death of the count in 1384, and his firm and wise government quickly won the affection and esteem of his new subjects. He encouraged judiciously arts, manufactures, and commerce, and his territory—a kingdom in extent—was one of the best governed in Europe. During the minority and subsequent imbecility of his

nephew, Charles VI. of France, he was obliged to take the helm of affairs, and preserve the state from insurrection and sedition within and the attacks of the English without. He died April 27, 1404.

Philip the Good (*Philippe le Bon*), Duke of Burgundy, the son of Jean 'Sans-peur' by Margaret of Bavaria, and grandson of Philip the Bold, was born at Dijon, the capital of the duchy, June 13, 1396, and, on the assassination of his father on the bridge of Montereau at the instigation of the dauphin (afterwards Charles VII.), succeeded to the duchy of Burgundy. Bent on avenging the murder of his father, he entered into an offensive and defensive alliance with Henry V. of England at Arras in 1419, at the same time recognising him as the rightful regent of France, and heir to the throne after Charles VI.'s death. This agreement, which disregarded the Salic law, was sanctioned by the king, parliament, university, and States-general of France in the treaty of Troyes (1420), but the dauphin declined to resign his rights, and took to arms; he was, however, defeated at Crevant (1423) and Verneuil (1424), and driven beyond the Loire. Some disputes with the English prompted Philip to conclude a treaty with the king of France in 1429. However. the English, by ceding to him the province of Champagne, and paying him a large sum of money, gained him back to their side. At this time, by falling heir to Brabant, Holland, Zealand, and the rest of the Low Countries, he was at the head of the most flourishing and powerful realm in western Europe; but though much more powerful than his superior, the king of France, he preferred to continue in nominal subjection. Smarting under some fresh insults of the English viceroy, and strongly urged moreover by the pope, he made a final peace (1435) with Charles, who gladly accepted it even on the hard conditions which Philip prescribed. The English, in revenge, committed great havoc among the merchant navies of Flanders, which irritated Philip to such an extent that he declared war against them, and, in conjunction with the king of France, gradually expelled them from their French possessions. The imposition of taxes, which were necessarily heavy, excited a rebellion, headed, as usual, by the citizens of Ghent, but the duke inflicted upon them a terrible defeat (July 1454), though he wept over a victory bought with the blood of 20,000 of his subjects. The later part of his reign was filled with trouble caused by the quarrels between Charles VII. and his son, the Dauphin Louis (afterwards Louis XI.), who had fled from his father's court, and sought shelter with Philip, although, after ascending the throne, far from showing gratitude, he tried in the most dishonourable manner to injure his benefactor. Philip died at Bruges, July 15, 1467, deeply lamented by his subjects. Under him Burgundy was the most wealthy, prosperous, and tranquil state in Europe; its ruler was the most feared and admired sovereign of his time, and his court far surpassed in brilliancy those of his contemporaries. Knights and nobles from all parts of Europe flocked to his jousts and tournaments. See Barante's *Histoire des Ducs de Bourgogne de la Maison de Valois.*

Philiphaugh, on Yarrow Water, 3 miles WSW. of Selkirk, the property from 1461 till 1889 of the line of the 'Outlaw Murray' of the ballad. Here, on 13th September 1645, Montrose (q.v.) was defeated by David Leslie, who butchered more than a hundred Irish prisoners. See Craig-Brown's *Selkirkshire* (1886).

Philip Neri, St. See Neri.

Philippeville, a seaport of Algeria, the harbour of Constantine, from which it lies 54 miles NNE. by rail. There is a magnificent harbour (1882) protected by two moles, one 4590 feet long, the other 1310 feet. The town is quite new, having been built since 1838 on the site of the ancient *Rusicada.* The imports and exports together reach £3,500,000 per annum. Pop. (1872) 10,267; (1891) 15,788.

Philippi, a city of Macedonia. It was named after Philip II. of Macedon (q.v.), who enlarged it because of the gold-mines in its neighbourhood. It is famous on account of the two battles fought in 42 B.C. between Antony and Octavianus on the one side and the republicans under Brutus and Cassius on the other, in the second of which the republic finally perished. The apostle Paul founded a Christian church here, to which one of his epistles is addressed.

Philippians, Epistle to the, the latest of the four letters that claim to have been written by the apostle Paul during his captivity (see Paul). The Philippian Church was looked upon with peculiar tenderness and affection by the apostle. It was the first-fruits of his mission in Europe; its members were singularly kind to him; more than once, when he was labouring in other cities, they sent him contributions, that he might not be burdensome to his new converts, and now they had despatched one of the brethren—Epaphroditus—all the way to the place of his captivity with presents for him, knowing that he was in bonds, and suspecting (as was in fact the case) that he might be in straits for his daily bread. His letter to them, of which Epaphroditus, on his return journey, was the bearer, is the 'most epistolary of all the epistles;' though containing important doctrinal matter, it is characterised primarily by its warm expression of personal feelings towards his friends at Philippi. The external evidence in favour of the genuineness of this epistle is exceptionally strong; it is alluded to by Polycarp, and enumerated among the Pauline writings both by Marcion and by the writer of the Muratorian canon. The arguments of Baur and others against its genuineness, which turn purely on questions of biblical theology, such as the compatibility of Phil. ii. 6–11 with 1 Cor. xv. 45–49, or of Phil. iii. 6–11 with certain other expressions in the undisputed writings, still find some supporters (one of the latest and ablest being Holsten); but they are not regarded as convincing even by Hilgenfeld, Schenkel, Weizsäcker, Pfleiderer, or Harnack. There are commentaries on Philippians by Meyer, Weiss, Ellicott (*Philippians, Colossians, and Philemon,* 3d ed. 1865), Lightfoot (6th ed. 1881), and C. J. Vaughan (1882).

Philippics, originally the three orations of Demosthenes against Philip of Macedon. The name was afterwards applied to Cicero's fourteen orations against the ambitious and dangerous designs of Mark Antony. It is now commonly employed to designate any severe and violent invective, whether oral or written.

Philippine Islands, a large insular group forming a northern section of the Eastern Archipelago, from which it is separated by the two profound abysses of the Sulu (Mindoro) and Celebes Seas, 2000 to 4000 fathoms deep. But these seas are enclosed by the three insular chains of Palawan, with Balabac in the north, Sulu in the centre, and Sanguir with Sias in the south, all of which lie in shallow waters, and form a geological connection between the Philippines and Borneo in the south-west and the Philippines and Celebes in the south. The archipelago, which is washed on the east side by the Pacific Ocean (3000 fathoms) and in the north-west by the China Sea (2000 fathoms), lies in 4°—21° N. lat. and 117°—127° E. long., and comprises a vast aggregate of over 2000 islands

of all sizes, ranging from mere rocks and reefs to the great lands of Luzon and Mindanao, the former rather more, the latter somewhat less, than 40,000 sq. m. in extent. The other chief members of the group, collectively called Visayas, are Mindoro, 9000 sq. m.; Palawan (Paragua), 5500; Samar, 5000; Panay, 4500; Negros, 4300; Leyte, 3000; Cebu and Bohol, both 1500; Masbate, 1200; total area, 116,000; population variously estimated at from 7,500,000 to 9,500,000.

The archipelago is disposed nearly due north and south, and is essentially mountainous and volcanic, lying in the direct line of the vast igneous chain which sweeps round from Sumatra and Java through the Lesser Sunda groups and the Moluccas northwards to Formosa and Japan. In the Philippines the first link in this system going southwards is the volcanic islet of Babuyan on the north coast of Luzon; but beyond the remarkable volcano of Taal (1320 feet), near Manilla Bay, the chain ramifies into an eastern and a western branch, which traverse the whole of the archipelago, and which are continued seawards by the insular chains of Sulu and Sanguir. The eastern branch develops the lofty cones of Mayon (9000 feet) and Bulusan at the south-eastern extremity of Luzon, while the western branch gives rise to those of Malaspina and Bacon in Negros and Camiguin near the north coast of Mindanao; in this island the two chains converge at the head of the Gulf of Davao, where they culminate in Apo (10,400 feet), highest point in the Philippines. These various ranges, which cover nearly the whole surface of the archipelago, leaving room for scarcely any plains except about the lower courses of the rivers, consist mainly of very old eruptive rocks, in many places covered by later tertiary, quaternary, and modern scoriæ and lavas. The underground forces are still active, and reveal themselves by tremendous eruptions, such as those of Mayon in 1766 and of Daraga in 1814, and especially by earthquakes, which are almost continuous, keeping the seismographs of the observatory at Manilla in a constant state of vibration. Manilla itself was nearly destroyed by the earthquake of 1863, which was followed by the disastrous convulsions of 1872 and 1880 at Surigao and in many parts of Mindanao. The navigation of the inland waters is endangered not only by these disturbances, but also by the conflicting currents caused by opposing tidal waves, and by the cyclones, here called typhoons, which range as far south as about 10° N. lat. (see Map at ASIA).

Owing to the parallel disposition of the mountain-ranges, space is afforded for the development of several large rivers, such as the Cagayan (Rio Grande), which drains about one-fourth of Luzon, flowing for 220 miles northwards between the Sierra Madre and the North Cordillera east and west; the Agno and Pampangan on the west side of the same island; and in Mindanao the Agusan (Butuan), navigable by large vessels for over 60 miles, and the Rio Grande di Mindanao, which flows from Lake Magindanao in the centre of the island first south-west then north-east to Illana Bay in the Celebes Sea. This river is joined by the emissaries of several other lakes, and a characteristic feature of the landscape in most of the islands is the large number of lacustrine basins, which send their overflow through short coast-streams to all the surrounding waters. The most important and best known of these emissaries in Luzon are the Pansipit, which drains Lake Bourbon, and the Pasig, which flows from the Laguna de Bay to Manilla. Several of the basins appear to be flooded craters, while others are of marine origin, bays and inlets cut off from the sea by the eruptive matter ejected from the neighbouring volcanoes in former geological epochs.

Thanks to the general elevation of the land, and the prevailing sea-breezes, the climate, although moist and hot, is less insalubrious than that of most tropical lands. The fevers are generally of a somewhat mild, intermittent type, and the most dreaded maladies are consumption, dysentery, and anæmia; leprosy exists in Luzon, but its ravages are confined to small areas. As elsewhere in the Eastern Archipelago, there are two seasons, a wet and a dry, which are determined by the trade-winds, but which, owing to the peculiar configuration of the land, may be said to go on simultaneously. Thus, for all the southern and western slopes, the south-west monsoon is the wet, the north-east the dry season, the recurrence of these periods being reversed on the opposite slopes of the same ranges. At Manilla, which is exposed to the south-west winds, the rains last from June to November, dry weather for the rest of the year; but this succession is elsewhere constantly modified, especially by the trend and altitude of the mountain-chains. On the other hand, the temperature varies little throughout the year, ranging from about 77° F. in December (the coldest month) to 86° F. in May (the hottest month), while the greatest extremes recorded at the Manilla Observatory are not more than 25 degrees (66°—91°). But the rainfall varies enormously, from $\frac{1}{3}$ inch in March to 20 inches in August, with a yearly average of 68 to 70 inches.

The indigenous flora, which is nowhere surpassed in variety and exuberance, indicates a long connection of the Philippines with Indo-Malaysia, and more transitory relations with Austro-Malaysia, through Celebes. Thus all the local genera are represented in the Great Sunda Islands and Malay Peninsula, but only very few in the Australasian world; absolutely independent forms are extremely rare, and generally represented only by a single type. Vast spaces are still covered with magnificent primeval forests containing a great number of dyewoods, fine, hard-grained, medicinal and other useful plants, such as ebony, sapan, tamarind, guinguina, the incorruptible magkono (a myrtacean), banyan, cocoa-nut, pandanus, nipa, and many other palms, bamboo, tree-ferns. Specially numerous are the fibrous plants, such as the gigantic bejuco, the buri, cabonegro, and abaca (Manilla hemp). On the plantations are grown several varieties of rice, maize, sugar-cane, cotton, coffee, and tobacco, the last mentioned second only to that of Cuba. Above 6000 feet the forest and alpine floras are almost exclusively Malaysian, and nearly identical with those of Borneo and Sumatra.

The native fauna is remarkable for the total absence of many large mammals, such as the tiger, elephant, rhinoceros, bear, tapir, orang-outang, which nevertheless occur in the Sunda Islands. Hence the only dangerous animals are the crocodile, snakes, and some other reptiles. The largest wild mammal is the buffalo, and next to it the gibbon, besides which there are several other species of apes and lemurs, three or four varieties of antelope, and a small deer resembling the Javanese *muntjac*. The carnivora are chiefly represented by several species of civet, the insectivora by the porcupine, and bats and squirrels abound in all the woodlands. Birds are very numerous, and the gallinacean family especially presents some remarkable forms, such as the laburgo (*Gallus baukiva*) and the bulicsigay, noted for its size, courage, and beautiful plumage. An endless variety of forms is also offered by the insect world, while the fresh and marine waters abound in fishes, turtles, molluscs (including both the pearl and mother-of-pearl oyster), sponges (euplectella and other exquisite varieties).

Of minerals the most widely diffused are coal

and iron; copper also occurs, as well as gold, lead, sulphur, cinnabar, quicksilver, alum, besides jasper, marble, and fine building stones. Thermal waters, chiefly sulphurous and ferruginous, occur in many places, especially in Luzon. But the mineral resources of the archipelago are little developed, and mining operations are carried on in the most primitive manner.

The original inhabitants of the Philippines were undoubtedly the Negritos (*Actas, Atas, Itas*), who at one time occupied the whole of the archipelago, but are now reduced to a few isolated groups numbering altogether less than 20,000, scattered over the remoter parts of Luzon, Negros, Mindanao, and several other islands. Half-caste Negrito communities are extremely numerous, this indigenous element having almost everywhere amalgamated with the intruding Indonesian and Malay peoples, who at present constitute the great bulk of the population. The Indonesians (see MALAYS) are mostly 'Infieles' (i.e. pagans), whereas nearly all the Malays are either 'Indios' (i.e. Roman Catholics) or 'Moros' (i.e. Mohammedans). Like the allied races of Sumatra, Borneo, and Polynesia, the Indonesians are distinguished by their tall stature, muscular frames, light-brown complexion, and regular features. Their chief tribes are the Apayaos, Tinguianes, Calanas, Guinaanes, Gaddanes, Igorrotes, Ifugaos, and Ilongotes of Luzon, about 60,000 altogether; the Cimarrones, Samars, and others of the Visayas, about 20,000; the Subanos, Manobos, Mandayas, Bilans, Guiangas, and Bagobos of Mindanao, where they are most numerous, 300,000, giving a total of about 380,000 for all the Indonesian tribes. The Moros (Orang-Islam, or Mohammedan Malays) are now reduced to from 250,000 to 300,000, chiefly confined to Palawan and Mindanao (Illanos, Lutancas, Sanguiles). All the rest of the Malays are Indios, or at least nominal Catholics, and comprise two main divisions, the northern Tagals of Luzon, about 3,000,000, and the central Visayas (Bisayas) of the Visayas Islands and parts of Palawan and Mindanao, about 2,500,000. The Tagal and Visayan languages are the most highly developed of all the Malayo-Polynesian forms of speech, and are gradually absorbing all the other numerous dialects of that family current throughout the archipelago.

Discovered in 1521 by Magellan, who was killed on the islet of Mactan on April 27 of that year, the Philippines were officially annexed to Spain in 1569, and till 1898 remained an integral part of the Spanish dominion, though some parts of the interior of Mindanao were never completely subjugated. Spanish rule was oppressive, taxation monstrous, and the tyranny of the religious orders unrestrained, and risings have repeatedly taken place—as in 1872. A rebellion in 1896 went on till the Spanish-American war began in 1898. The first serious blow in the war was given in Manila harbour (May 1), when the Spanish fleet was totally destroyed by an American squadron under Admiral Dewey. As a result of the war the Philippines were ceded to the United States on a payment of £4,000,000 (November 1898). The Philippine leader Aguinaldo, however, continued a desultory war with the United States forces till into the year 1901.

Besides Manila (q.v., the capital), other towns are Lipa, pop. 43,000; Banang, 35,000; Batangas, 35,000; Laoag, 30,000; San Miguel, 35,000; Cabaera, 30,000; Ilo-ilo, 24,000; and Cavite (q.v.). The Europeans in the islands number about 25,000, and the principal industries are in the hands of the Chinese, who number about 100,000. The exports amount to over £4,000,000, and consist chiefly of sugar (£1,600,000 in 1896), hemp (£1,500,000), tobacco-leaf (£500,000), cigars (£150,000), copra (£375,000). The chief imports are rice, flour, coal, petroleum, &c., and amount to over £2,000,000. There is a considerable trade with the United Kingdom; in 1897 the imports from Britain were £400,000 in value, and the exports thither £1,278,830.

Philippo'polis, capital of Eastern Roumelia or Southern Bulgaria, on the navigable Maritza, 110 miles by rail W. by N. of Adrianople. It manufactures silk, cotton, tobacco, leather, &c., and prepares and exports otto of roses (to the value of £55,000). Pop. (1893) 36,033, of whom nearly half are Turks, Greeks, and others than Bulgarians. An outpost of the Macedonian kingdom, it was ruined by the Goths, captured by the Turks (1363), destroyed by an earthquake (1818), burned (1846), and occupied by the Russians (1878).

Philippsburg, a town of Baden on the Rhine's right bank, 16 miles N. of Carlsruhe. Fortified till 1800, it was often besieged. Pop. 4922.

Philips, AMBROSE, minor poet, was descended from a Leicestershire family, and born about 1671. He was educated at St John's College, Cambridge, and contributed to the university memorial verses on the death of Queen Mary. Coming up to London he became intimate with Addison and Steele, did hack work for Tonson, and first gained a reputation by the 'Winter-piece' in the *Tatler* (No. 12) and the six Pastorals which opened the sixth volume of Tonson's *Miscellany* (1709), of which the first four volumes had been edited by Dryden. Strangely enough the same volume closed with the Pastorals of the young Pope, whose jealousy was aroused by Tickell's praising Philips and passing over himself, in his paper in the *Guardian* on Pastoral Poetry from Theocritus downwards. Pope took a characteristic revenge by a paper in the *Guardian* (No. 40), in which the worst of the verses of Philips were ironically exalted above the best of his own. His design he disguised with such dexterity that, though Addison discovered it, as Dr Johnson tells us, Steele was deceived, and was afraid of displeasing Pope by publishing his paper. Philips is said to have hung up a rod in Button's Coffee-house with which he threatened to chastise Pope on the first occasion. Pope nourished his anger against him, and all the more after his own quarrel with Addison to whose circle Philips belonged, and did not forget him in the *Dunciad*. Philips supported the government in the columns of the *Free-thinker*, and was rewarded by being made secretary to Archbishop Boulter in Ireland. Later he sat for Armagh, acted as secretary to the Lord Chancellor and judge of the Prerogative Court, and after his patron Boulter's death returned to London, and died in 1749. Of his plays, *The Distress'd Mother* (1712)—an adaptation from Racine's *Andromache*—was warmly praised in the *Spectator*; *The Briton* and *Humphry, Duke of Gloucester* lived only long enough to be damned. His *Pastorals* are vigorous and easy yet graceful verse, but lack the charm that belongs to Gay, whose *Shepherd's Week* was really written at Pope's

instigation to take Philips off. Some of his odes, addressed to children, and written with infantine simplicity of diction, earned him from Henry Carey the lasting nickname of 'Namby-Pamby.'

See Johnson's *Lives*, and Pope's Correspondence in Elwin and Courthope's edition.

Philips, or PHILLIPS, EDWARD, the elder of the two nephews brought up and educated by Milton, the sons of his sister Anne, whose husband E. Phillips held a government office in Chancery, and died in 1631, leaving two sons to Milton's care. Edward Philips was born in 1630, and became a student of Magdalen College, Oxford, but left in 1651 without taking a degree. In 1663 he was tutor to the son of John Evelyn at Say Court in Essex. He is mentioned in Evelyn's Diary as 'not at all infected by Milton's principles,' yet certainly he entertained a great respect and admiration for his uncle, and not only extolled Milton in his *Theatrum Poetarum* as 'the exactest of heroic poets,' 'who hath revived the majesty and true decorum of Heroic Poesy and Tragedy,' but has left us a valuable though short and fragmentary *Life* of the poet. This was originally prefixed (1694) to a translation of Milton's *Letters of State*, but is now most accessible in Godwin's *Lives of E. and J. Philips* (1815, pp. 350-383), and is, as Johnson says, 'the only authentic account of Milton's domestic manners.' Of his numerous works may be mentioned a complete edition (the first) of the *Poems of Drummond* of Hawthornden (1656); *New World of English Words* (1658), a kind of dictionary, which went through several editions; the *Continuation* of Baker's *Chronicle of the Kings of England* (1665); *Theatrum Poetarum, or a Complete Collection of the Poets* (1675); the *Tractatulus de Carmine Dramatico Poetarum* in the 18th edition of Buchler's *Thesaurus* (1679); and *Tractatulus de Lingua Latina* (1682). Milton, says Aubrey, made his nephews songsters, and sing from the time they were with him, and verses by both are found in *Ayres and Dialogues for One, Two, and Three Voices*, by Henry Lawes (1653). Edward is supposed to have died shortly after the publication (1694) of the *Letters of State*.

Philips, JOHN, Milton's younger nephew and more peculiar charge, born in 1631, was, like his brother Edward, educated by his uncle, and frequently acted as his amanuensis. It may be supposed that Milton had formed a high opinion of his literary capability, since he entrusted to John rather than Edward the writing of the *Responsio ad Apologiam pro Rege et Populo Anglicano* (1652), himself correcting it with the utmost care. But if John was Edward's superior in ability, he was greatly his inferior in character, and persistently displayed an unnatural animosity to his uncle and benefactor. His next work was *A Satyr against Hypocrites* (1655), a bitter anti-Puritan poem and attack on Cromwell, written with considerable talent, but in a strain of coarse buffoonery. Somewhat in the style of Chaucer, he describes a Sunday in Cromwell's time, a christening, and a Wednesday fast with the extravagant supper at night. This production was frequently reprinted, and must have caused Milton no small disappointment and annoyance. In 1660 John amused himself and the world with his *Montelion* or the *Prophetical Almanac*, a low, scurrilous work, which was, however, extremely successful; he was also a most industrious translator, and in little more than a year (1677) published three large folio translations, *Almahide*, from the French of Madame de Scudéry, on which was founded Dryden's tragedy, *The Conquest of Granada;* Calprenède's *Pharamond:* and Tavernier's *Voyages*. Philips (or Phillips) wrote many scurrilous pamphlets, and died in 1706.

Philips, JOHN, described on the monument in Westminster Abbey erected by Sir Simon Harcourt to his memory as a second Milton. He was the author of three very popular poems, *The Splendid Shilling*, a burlesque of Milton's manner; *Cider*, an imitation of Virgil; and *Blenheim*, a Tory celebration of Marlborough's great victory. He was born in 1676, but, curiously enough, was registered at Winchester as five years, and at Christ Church, Oxford, as six years younger than he really was. He died in 1708, and was buried in the cathedral at Hereford.

Philips, KATHERINE, 'the matchless Orinda,' was born the daughter of a respectable Presbyterian London merchant, on New-year's Day 1631. A precocious child, she early became strongly royalist in feeling, and in her seventeenth year she married a worthy Welsh gentleman, James Philips of Cardigan Priory. Her earliest poem was an address to Henry Vaughan the Silurist, on the appearance of his *Olor Iscanus* (1651). About the same time she seems to have assumed her melodious *nom-de-plume* of Orinda, having formed among her neighbours of either sex a Society of Friendship, the members of which must needs be re-baptised—the ladies as Lucasia, Rosania, Regina, Valeria, Polycrite; the gentlemen as Palæmon, Silvander, Antenor (her own husband), and Poliarchus (Sir Charles Cotterel, her greatest friend, her forty-eight *Letters* to whom were published in 1705). Orinda is our earliest sentimental writer, and she has tears at will even for the marriages of the lady-members, which she resents as outrages on the sufficiency of friendship. Yet she was a worthy woman and good wife, despite her overstrained sentimentality, and deserved the honour of a dedication from Jeremy Taylor (*Discourse on the Nature, Offices, and Measures of Friendship*, 1659). She went to Dublin in 1662, and here Roger, Earl of Orrery, and the rest gave her a flattering reception. On a visit to London she caught smallpox, and died at thirty-three, June 22, 1664. At Dublin she translated Corneille's *Pompée*, and in her last year the greater part of his *Horace*. Her poems were surreptitiously printed at London in 1663, but an authoritative edition was issued in 1667. The matchless Orinda's poetry has long since faded into forgetfulness, despite the chorus of contemporary praise from Cowley and every poet of note. Keats found her poems in 1817 while writing *Endymion*, and in a letter to Reynolds speaks of them as showing 'a most delicate fancy of the Fletcher kind.' Mr Gosse conjectures the scarce volume of *Femule Poems* (1679) 'written by Ephelia' to have been the work of Orinda's only daughter, Joan (born about 1654), who married Mr Wogan of Pembrokeshire in 1679.

See the admirable essay by Mr Edmund Gosse in *Eighteenth Century Studies* (2d ed. 1885).

Philipstown, a market-town of King's County, Ireland, 8 miles E. of Tullamore and 49 miles W. by S. of Dublin, takes its name from Queen Mary's consort, Philip of Spain. Pop. 829.

Philistines (Heb. *Pelishtim;* Gr. *allophuloi*, 'strangers'), a people mentioned in the Bible as being in frequent contact with the Jews, and who lived on the coast of the Mediterranean, to the south-west of Judæa, from Ekron towards the Egyptian frontier, bordering principally on the tribes of Dan, Simeon, and Judah. Our information about the origin of the Philistines is extremely obscure. The genealogical table in Genesis (x. 14) counts them among the Egyptian colonies (the 'Casluhim, out of whom came the Philistines'); according to Amos, ix. 7, Jeremiah, xlvii. 4, and Deuteronomy, ii. 23, they came from Caphtor—formerly, from mere resemblance of the word, identified

with Cappadocia. Others have, groundlessly, derived them from the Pelasgians. Of late the tendency is to believe that the Philistines, who were undoubtedly immigrants, came from Crete, the collocation of Cherethites (Cretans) and Pelethites (2 Sam. viii. and xv.) favouring this view. But they seem to have become thoroughly Semitised in speech, their language being undistinguishable from pure Hebrew; and their gods Baalzebub and Dagon (q.v.) are apparently Semitic.

It is doubtful if Abimelech, king of Gerar (Gen. xxi., xxvi.), was king of this people or merely of the country afterwards Philistine; more probably the expulsion of the Danites (Judges, v., xviii.), presumably before the new invaders, marks their first appearance as aggressive enemies. They were subject to five princes, who ruled over the provinces of Gaza, Ashdod, Askalon, Gath, and Ekron. They were so powerful at the time of Eli that they carried away the ark itself. Under Samuel their rule was terminated by the battle of Mizpah. Saul was constantly engaged in warding off their new encroachments, and at Gilboa he and his sons fell in a disastrous battle against them. David succeeded in routing them repeatedly; and under Solomon their whole country seems to have been all but incorporated in the Jewish empire. The internal troubles of Judæa emboldened the Philistines once more to open resistance; but Hezekiah subdued their country with the aid of the Egyptians. The Assyrians afterwards took Ashdod; and in the time of the Maccabees the Philistines were Syrian subjects; by the time of Herod the name of the country had long been lost in that of Palestine. A civilised, agricultural, commercial, and warlike nation, they traded largely, and their wares seem to have been much sought after.

See the various histories of the Israelites cited at JEWS; Schrader's *Keilinschriften* (2d ed. 1883); Wright's *Comp. Gram. of the Semitic Languages* (1890).—German students call those who have ceased to be students, as well as non-students, tradesmen, &c., *Philister* or Philistines; hence the further sense of 'uncultured,' 'narrow-minded,' in which application the term has come to be used in Britain, especially through Mr Matthew Arnold's influence.

Phillimore, SIR ROBERT JOSEPH, born 5th November 1810, studied at Oxford, and, after serving in the Board of Control, had a brilliant career at the bar. He sat in parliament as a Whig from 1853 to 1857; and held in succession the offices of Advocate-general (1862, when he was knighted), Judge Advocate-general (1871), judge of the Arches Court (1867–75) and of the High Court of Admiralty (1867–83). Made a baronet in 1881, he died 4th February 1885. His most important works are his *Commentaries upon International Law* (4 vols. 1854–61; 3d ed. 1879), and his *Ecclesiastical Law of the Church of England* (2 vols. 1873; supp. 1876).

Phillip, JOHN, R.A., was born, an old soldier's son, at Aberdeen on 19th April 1817. He was apprenticed to a painter and glazier, but in 1836 was sent by Lord Panmure to London, where he was ere long admitted to the schools of the Royal Academy. In 1839 he began to exhibit in the Academy Exhibition. Most of his early subjects were of Scotch character, such as a 'Scotch Fair' and 'Baptism in Scotland.' In 1851 he went to Spain in search of health. On his return he became noted as a painter of the habits and customs of the Spanish people, and was known as 'Spanish Phillip.' In 1853 he exhibited 'Life among the Gypsies at Seville.' His pictures for 1854–55, 'A Letter Writer of Seville' and 'El Paseo,' were purchased by the Queen. In 1857 he became A.R.A., in 1859 R.A. 'The Marriage of the Princess Royal' (1860) was a success, as was also the 'House of Commons,' containing upwards of thirty portraits of the leading members of both sides of the House. But his main triumphs were in Spanish subjects, such as 'La Gloria' (1864) and 'El Cigarillo' (1864). He twice again visited Spain, was in Italy in 1866, and died in London, 27th February 1867. His 'Early Career of Murillo' sold in 1895 for 3800 guineas. He was a great colourist, and his light effects were broad and strong.

Phillips. See PHILIPS, HALLIWELL-PHILLIPPS.

Phillips, WENDELL, abolitionist, was born 29th November 1811, at Boston, Massachusetts, the son of the first mayor of the city (1822). He graduated at Harvard with Motley in 1831, studied law there, and was called to the bar in 1834. But before clients came he had been drawn away from his profession to the real work of his life. A timely and important speech in Faneuil Hall in 1837 made him at once the principal orator of the anti-slavery party; and henceforth, until the president's proclamation of 1st January 1863, he was Garrison's loyal and valued ally, his lectures and addresses doing more for their cause than can well be estimated. He also championed the cause of temperance, and that of women, and advocated the rights of the Indians. In 1870 he was nominated for governor by the Prohibitionists and the labour party. He died 2d February 1884. His speeches and letters were collected in 1863 (new ed. 1884); and there is a Life by G. L. Austin (Boston, 1888).

Phillipsburg, a city of New Jersey, on the Delaware River (crossed by two railroad bridges), opposite Easton, at the western terminus of the Morris Canal, and 73 miles W. of New York by rail. It contains a rolling-mill and several foundries, boiler- and locomotive-works, &c. Pop. (1890) 8644.

Philoctetes, a famous archer, the friend and armour-bearer of Hercules, who bequeathed him his bow and poisoned arrows. As one of the suitors of Helen, he led seven ships against Troy; but being bitten in the foot by a snake (or, according to one story, wounded by his own arrows), he fell ill. As his wound gave forth an unendurable stench, the Greeks left him on the island of Lemnos, where for ten years he spent a miserable life. But an oracle declared that Troy could not be taken without the arrows of Hercules, so Ulysses and Neoptolemus were despatched to bring Philoctetes to the Greek camp; where, healed by Æsculapius or his sons, the restored hero slew Paris, and helped powerfully in the taking of Troy. After the war he settled in Italy. A play of Sophocles is named from him.

Philo Byblius. See PHŒNICIA, p. 133.

Philo Judæus, the Philosopher, was born at Alexandria, most probably about 20–10 B.C. Belonging to a wealthy family—his brother, according to Josephus, was the alabarch or arabarch Alexander—he received the most liberal education; and such was his zeal for learning that at a very early age he had passed through the ordinary course of Greek studies. Although every one of the different free sciences and arts included in the *Encyclika*, he says, attracted him like so many beautiful slaves, he yet aimed higher, to embrace the mistress of them all—Philosophy. Metaphysical investigation was the only thing which, he tells us, could give him anything like satisfaction or pleasure. He was intimately acquainted with Plato, the Greek tragedians, and Homer, and he speaks with the warmest praises of the Stoics and the Pythagoreans. With these and especially with Plato his affinities are closest—an old proverb runs: ἢ Πλάτων φιλωνίζει ἢ Φίλων πλατωνίζει. Yet with all his Greek culture he remained a Jew, holding Jewish philosophy as the highest wisdom,

the divine revelation given to Moses as the source of all true knowledge in religion. He had completely mastered the literature of his nation, but, strange to say, was by no means a profound Hebrew scholar. When over fifty years of age he went to Rome as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the imperial edict. His *De Legatione ad Caium* gives a vivid account of this embassy. Of his life we know little except what is recorded above, and that he once went to Jerusalem. His second mission to Rome, to the Emperor Claudius, on which occasion Eusebius reports that he made the acquaintance of the apostle Peter, is doubtful.

The religious and philosophical system of Philo, however, is most minutely known, and deserves the most careful study on account of the vast influence which it has exercised both on the Jewish and Christian world. To understand his system aright it will be necessary to recall to memory the strange mental atmosphere of his day. The Alexandrines had endeavoured to make Judaism palatable to the refined Greeks, by proving it to be identical with the grandest conceptions of their philosophers and poets, and had quite allegorised away its distinctive characteristics. Philo was the first man who, although himself to a great extent imbued with allegorising tendencies, made a bold and successful stand against a like evaporisation of the revealed religion of his fathers; which, indeed, in many cases had led people to throw off its yoke also outwardly. Himself a most zealous champion of Judaism, his bitterness knows no bounds in rebuke of those co-religionists who tried to defend their secret or overt apostasy by scoffing at the Law itself, who were 'impatient of their religious institutions, ever on the lookout for matter of censure and complaint against the laws of religion, who, in excuse of their ungodliness, thoughtlessly argue all manner of objections.' He cannot understand how Jews, 'destined by divine authority to be the priests and prophets for all mankind,' could be found so utterly blind to the fact that that which is the position only of a few disciples of a truly genuine philosophy—viz. the knowledge of the Highest—had by law and custom become the inheritance of every individual of their own people; whose real calling, in fact, it was to invoke the blessing of God on mankind, and who, when they offered up sacrifices 'for the people,' offered them up in reality for all men.

To Philo the divinity of the Jewish law is the basis and test of all true philosophy. Although, like his contemporaries, he holds that the greater part of the Pentateuch, both in its historical and legal portions, may be explained allegorically—nay, goes so far even as to call only the Ten Commandments, the fundamental rules of the Jewish theocracy, direct and immediate revelations, while the other parts of the Book are owing to Moses—he yet holds the latter to be the interpreter specially selected by God, to whose dicta in so far also divine veneration and strict obedience are due; and again, while admitting that many explanations of a metaphysical nature may be given to single passages, yet demands in general that their literal meaning shall not be tampered with. This literal meaning, according to him, is the essential part, the other explanations are mere speculation—exactly as the Midrash and some Church Fathers hold. At the same time it is true that, without denying the literal meaning, again and again he puts forward the allegorical meaning as the one really divine, and indeed sometimes he treats the literal meaning as absurd. Only the allegorical method in his hands differed in so far from that of his contemporaries that to him these interpretations—for which he did not disdain sometimes even to use the numbers symbolically, or to derive Hebrew words from Greek roots, and the like—were not a mere play of fancy, in which he could exercise his powers of imagination, but, to a certain extent, a reality, an inner necessity. He clung to philosophy, as combined with the Law. If the former could be shown, somehow or other, to be hinted at in the latter, then only he could be that which all his soul yearned to be—viz. the disciple of both: a Greek, with all the refinement of Greek culture, and a Jew—a faithful, pious, religious Jew. Nay, he even urged the necessity of allegory from the twofold reason of the anthropomorphisms current in Scripture and from certain apparent superfluities, repetitions, and the like, which, in a record that emanated from the Deity, must needs have a special meaning of their own which required investigation and a peculiar interpretation. Yet this fanciful method never for one moment interfered with his real object of pointing out how Judaism most plainly and unmistakably was based upon the highest ethical principles.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally which treats of the Creation (κοσμοποιΐα) he allows allegory to take the reins out of his hands; in that on the Laws (νόμοι), on the other hand, he remains remarkably sober and clear, extolling the Mosaic legislation throughout at the expense of every other known to him. In a very few instances only is he induced to find fault, or to alter slightly, by way of allegory, the existing ordinances.

His idea of God is intended to be in the highest degree philosophical, though its religious significance is never lost sight of. God alone is the real Good, the Perfect, the final cause of all things, which ceaselessly flow outwards from Himself. God is only to be imagined as the primeval light, which cannot be seen by itself, but which may be known from its rays that fill the whole world. Being infinite and uncreated, He is not to be compared with any created thing. He has, therefore, no name, and reveals Himself only in designations expressive of this 'inexpressibility,' such as 'the Place' (the Talmudical *Makom*), because He comprises all space, and there is nothing anywhere besides Him. He is better than Virtue and Knowledge, better than the Beautiful and the Good (καλοκἀγαθία), simpler than the One, more blissful than Bliss. Thus He has properly speaking no quality, or only negative ones. He is the existing Unity or Existence itself (ὁ ὤν), comprised in the unpronounceable Tetragrammaton. As Creator, God manifests Himself to man, and in this phase of active revelation of God, which is as natural to Him as burning is to the heat, and cold to the snow, may be distinguished two distinct sides or essential properties, the Power and the Grace, to which correspond the two Scripture names of Elohim and Adonai. The *Power* also gives the laws and punishes the offender; while the *Grace* is the beneficent, forgiving, merciful quality. Yet, since there is not to be assumed an immediate influence of God upon the world, their respective natures being so different that a point of contact cannot be found, an intermediate class of beings had to be created to stand between both, through whom He could act in and upon creation—viz. the spiritual world of ideas, which are not only 'Ideals,' or types, in the Platonic sense, but real, active powers (δυνάμεις), surrounding God like a number of attendant Beings. They are His messengers, who work His will, and by the Greeks are called good *dæmons*, by Moses *angels*. There are very many different degrees of perfection among them. Some are immediate 'serving angels;' others are the souls of the pious, of the prophets, and the people of Israel, who rise higher up to the Deity; others,

again, are the heads and chief representatives of the different nations, such as Israel does not need, since they conceive and acknowledge the Everlasting Head of all Beings Himself. Collectively the Powers are used as equivalent to the nature or essence of God—his ideas or thoughts dominating and informing the universe; yet they are far from being substitutes for God. Zeller maintains that in Philo's doctrine of the Powers two representations cross each other—the religious notion of personal, and the philosophical of impersonal, mediators. Edersheim also asserts that here Philo's philosophy and theology are hopelessly at issue, the *δυνάμεις* being undoubtedly represented as *hypostases*, while yet they have no true personal subsistence. Dr Drummond refuses to admit that Philo imputed personality to the Powers, or that he identified them with the angels. Schürer maintains that we cannot deny definitely the personification of the *λόγοι* or *δυνάμεις*, since Philo conceived of them both as independent hypostases and as immanent determinations of the Divine existence.

The *Logos*, or Divine Reason, comprises all these intermediate spiritual powers in His own essence. It is the universal idea, the one supreme and all-embracing thought which unifies everything into a real cosmos—a property of God, and the representative of God in His relation to the created world. As such the Logos is the highest of the angels, the Beginning, the Name, the Word, the Primeval Angel, the first-born son of God, the second God (*δεύτερος θεός*, in opposition to *ὁ θεός*). As the expressed Thought of God it has a twofold aspect regarded as the *uttered* and the *inward* Logos, although this is not formally expressed by Philo. It becomes objective in the harmonies of the created world, and stands distinct from the same Thought when hidden in the silent depths of God, and known only to His omniscience. The Logos formed the world out of chaotic matter, regarded as a mass occupying space, and now considered as the *μὴ ὄν* of Plato, again as the *οὐσία* of the Stoics. Man is a microcosm, a little world in himself, a creation of the archetypal Logos, through whom he participates in the Deity, or, as Scripture has it, 'he is created in the image of God.' He stands between the higher and lower beings—in the middle of creation. The ethical principles of Stoicism Philo identified with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness towards fellow-men. Philo holds firmly the belief in immortality. Eternity is the motionless duration of unalterable being; time but the moving succession of ever-shifting phenomena. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by an eminence of virtue. There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Future recompense and punishment are not taken by him in the ordinary sense of the word. Virtue and sin both have all their rewards within themselves; but the soul, which is 'pre-existing,' having finished its course in the sublunar world, carries this consciousness with it in a more intense and exalted manner. Paradise is Oneness with God; there is no hell with bodily punishments for souls without a body, and no Devil in the Philonic system. Dr Drummond has succeeded in proving against Dähne and others that matter, though eternal, is purely passive, and not itself necessarily evil in Philo's teaching. The source of the imperfection is not in the material as opposed to the spiritual, but in the phenomenal as opposed to the eternal. The human *πνεῦμα* is itself an emanation from Deity, subject meantime to the bondage of sense, and the loftiest principle of ethics is the utmost possible renunciation of sensuousness. The direct vision of God is possible only for those souls which have been lifted out of themselves and illumined by renunciation and severe purity. And transcending this ecstasy is the complete deliverance from the body beyond the gates of death, when the soul that has freed itself in life from the bondage of sense returns again to its original condition as pure spirit.

Philo's Messianic notions are vague in the extreme, and he partly even interprets certain scriptural passages alluding to some future Redeemer as referring to the soul. Yet he indicates his belief in a distant time when some hero will arise out of the midst of the nation who will gather all the dispersed together; and these, purified by long punishments, will henceforth form a happy, sinless, most prosperous community, to which all the other nations will be eager to belong. Still the Messianic hope is very obscure, and Dähne's identification of the Logos with the Messiah is indefensible.

We have only been able to indicate, in the slightest of outlines, the principal features of Philo's theology and philosophy, without endeavouring to follow any one of the manifold systematic schemes into which his scattered half-obscure dicta have been pressed. His method of exegesis and the main elements of his religious philosophy passed into the Christian church, and exercised a powerful influence over its thinkers. Nor can Philo ever lose his importance in the history of thought as the earliest eclectic religious philosopher, the first to construct a real philosophy of religion, in which were harmonised the rational and the irrational—the results of speculative thought with the suppositions of a supernatural revelation.

Philo's writings are numerous, and their arrangement presents no small difficulty to the student. Many of his writings in the list given by Eusebius (*H.E.* ii. 18) are lost, but the bulk even of these have been preserved in the Fathers and early Christian writers, like Eusebius, who quote Philo to an enormous extent. Many detached portions have also been preserved in the *Florilegia* and similar compilations of the earlier Christian Parallelists. The first and very imperfect edition of the Greek text was that published by Turnebus (Paris, 1552), containing only thirty-nine treatises. The best is still that of Thomas Mangey (2 vols. folio, Lond. 1742), but a satisfactory collected edition is still a desideratum, neither that promised by Grossmann so long ago as 1829, nor that for which Tischendorf collected materials, ever having appeared. The *Libellus de Opificio Mundi* was edited by Leop. Cohn in 1889 as a specimen of a projected edition. Some writings of Philo preserved only in Armenian have been published in Latin translations by Jo. Bapt. Aucher (Venice, 1822, 1826); and Greek portions of greater or less extent have been given by Mai, Grossmann, Tischendorf, Cardinal Pitra, and Professor J. Rendel Harris (Cambridge Press, 1886). The more recently collected materials are contained in the hand edition of C. E. Richter (8 vols. Leip. 1828–30) and the Tauchnitz stereotype edition (8 vols. Leip. 1851–53). See the brief account of each book in Schürer's *Hist. of the Jewish People* (div. 2, vol. iii. 1886) in Clark's translation. An important contribution to Philo bibliography is that by L. Massebieau (Paris, 1889). There is an Eng. trans. by C. D. Yonge in Bohn's 'Eccles. Library' (4 vols. 1854–55).

More than three-fourths of what has come down to us from Philo consists of three chief works on the Pentateuch: (1) *Ζητήματα καὶ Λύσεις* (*Quæstiones et Solutiones*) —in Armenian—a short explanation of Genesis and Exodus in question and answer; (2) *Νόμων ἱερῶν ἀλληγορίαι*, a large allegorical commentary on Genesis, in which the history is interpreted as a system of

psychology and ethics, itself filling almost the whole of Mangey's first volume, and consisting of a series of sixteen special treatises; (3) a group of compositions intended as an *Exposition of the Mosaic legislation for non-Jews*, and falling naturally into three divisions—an Account of the Creation (κοσμοποιΐα, *De Opificio Mundi*), the Biographies of Virtuous Men, and the Legislation proper. Besides these have been preserved, either entire or in fragments, the following works: Περὶ βίου Μωϋσέως (*Vita Mosis*), Περὶ τοῦ πάντα σπουδαῖον εἶναι ἐλεύθερον (*Quod omnis probus liber*), Εἰς Φλάκκον (*Adversus Flaccum*) and Περὶ ἀρετῶν καὶ πρεσβείας πρὸς Γάϊον (*De legatione ad Caium*), Περὶ προνοίας (*De Providentia*), Ἀλέξανδρος ἢ περὶ τοῦ λόγον ἔχειν τὰ ἄλογα ζῷα (only in Armenian), Ὑποθετικά (known only from Eusebius), and Περὶ Ἰουδαίων.

Other works now generally regarded as spurious are *De Incorruptibilitate mundi*, *De Mundo*, and *Interpretatio Hebraicorum nominum*. The Philonic authorship of the *De Vita contemplativa* was attacked by Lucius (*Die Therapeuten*, 1879), but defended by Edersheim in Smith's *Dict. of Christ. Biography*, and with great ingenuity by F. C. Conybeare in his admirable edition of the text (1895).

See H. C. Ryle, *Philo and Holy Scripture* (1895); Herriot, *Philon le Juif* (Paris, 1898); Gfrörer, *Philo und die Alexandrinische Theosophie* (Stuttgart, 1831); Dähne, *Die Jüdisch-Alexandrinische Religions-Philosophie* (Halle, 1834); Keferstein, *Philo's Lehre von den göttlichen Mittelwesen* (Leip. 1846); Siegfried, *Philo von Alexandria als Ausleger des Alten Testaments an sich selbst und nach seinem geschichtlichen Einfluss betrachtet* (Jena, 1875); Zeller, in part iii. div. 2 of *Die Philosophie der Griechen* (3d ed. 1881); Edersheim's *Life and Times of Jesus the Messiah* (2 vols. 1883); and Principal Drummond's admirable *Philo-Judæus, or the Jewish-Alexandrian Philosophy in its Development and Completion* (2 vols. 1888).

Philo of Byblus. See PHŒNICIA.

Philology. The meaning of this term has varied curiously. As we find it first employed by Plato, it meant the love of discussion, limited practically to the moral and social questions in which Plato delighted; and the method of such discussion was the Socratic one. At Alexandria the 'philologer' was busied with all the knowledge of his day brought together for the first time in the great library of the Ptolemies. Thus, Eratosthenes, who applied this term to himself, was specially famous as a writer on astronomy. But the great scholars of Alexandria applied themselves with especial eagerness to the study of the older Greek literature. Men like Zenodotus and Aristarchus compared the numerous MSS. of Homer, selected the best texts, made lists of difficult words, called *glossæ*—the earliest dictionaries—and were the founders of the science of criticism by establishing canons on which they rejected what they deemed spurious in the copies before them. Two centuries later at Rome Cicero, who uses the word not unfrequently in his letters, applies it to study in general. But ever after the Alexandrian time 'philology' was essentially the intelligent critical study of the traditional learning of the past. It widened again at the revival of learning to include the study of grammar, rhetoric, poetry, archæology —in a word, all the 'humane' studies. And this wider sense clung to the word. Johnson in the last century defines a philologer as 'one whose chief study is language, a grammarian, a critick.' Yet Watts, whom he quotes as one of his authorities for the use of the word, says that 'studies called philological are history, language, grammar, rhetoric, poesy, and criticism.' In fact philology was the study which interpreted the best writings; and these writings were Greek and Latin; and in these languages were to be found the most noteworthy speculations on all matters of human interest. So philology had its special and its wider sense. Since the middle of the 19th century the use has been changing in a different direction. Through the discovery of Sanskrit the scientific comparison of Greek and Latin with other languages became possible. That study was called 'comparative philology.' But this term is cumbrous, and in England, and to some extent in France, it is customary to speak in this sense of 'philology' alone. So, whereas formerly philology meant pre-eminently the knowledge, grammatical, critical, exegetical, which enabled men to explain the most important literature of the world, it now is becoming limited to the study of language apart from the literature embodied in it—to the science which deals with the origin, development, and general character of the different families of speech throughout the world and of human speech as a whole: to which, therefore, the most highly cultivated languages may be not more important than languages which have hardly any literature or none at all: because such languages develop naturally, whereas literary languages are subject to artificial restraint. In Germany, it may be noted, this special study of language is called not 'Philologie' but 'Linguistik.'

It must not be supposed that this scientific study of language as an end in itself has superseded the older philology of a Bentley or a Porson. Rather, it has helped it by throwing light on the forms and meaning of words and phrases isolated or obscure in one language, but frequent and clear in another. But indeed the work of the critical scholar of the present day has been widened to a degree which could not have been realised three generations ago. First, the art of interpretation has been developed; the old storehouses of MSS. have been more fully searched; the principles of palæography are more widely known, so that we have many more scholars capable of dealing at first hand with MSS., of deciding upon their age, origin, and relative value. The sister-art of epigraphy, which deals with inscriptions, has ever-increasing material to work upon. Secondly, the science of archæology has been almost re-created. Explorations in all parts of the Hellenic world—Attica, Delphi, Peloponnese, Cyprus, and Asia Minor—especially the recent search in the Acropolis at Athens, have profoundly affected our ideas of Greek art, both plastic and constructive. The long-continued excavations at Pompeii have shown us the domestic life of the 1st century in the most minute detail. There can be no doubt that we have yet much to learn, and that the zeal of modern students will be equal to the task. Again, historical inscriptions and coins have corrected and supplemented the statements of ancient writers, and have often given us unexpected and perfectly trustworthy information as to periods unrepresented in any literature. These and other auxiliary sciences have given new life and meaning to the scholar's work. They make it at once more satisfying and more difficult: there is so much more to be known. Formerly a really great scholar could master the whole domain of knowledge; now every man must depend for something on the labours of others.

The study of philology, especially the study of grammar, after it was transplanted from Alexandria, flourished at Rome in the imperial time. It lingered on at Constantinople till the line of great grammarians ended in Priscian; while lexicography culminated later in the work of Photius and of Suidas. But it was in Italy that the study of antiquity became again a living thing: Italians in the 14th and 15th centuries discovered in Italy, Germany, and France works of the greatest Roman writers, such as Cicero and Lucretius, which had remained for generations buried in convents; it was to Italy that learned Greeks, especially after the sack of Constantinople, came to teach the Greek language at Florence and at Venice, and

brought with them the MSS. of Thucydides and of Plato, to be translated by Valla and by Ficinus; and it was in Italy that the results of their labours were first published to the world at large by the great houses of the Manucci and the Giunta. But with the exception of Faerno Italy had no great scholar. Yet by its connection with France it produced scholars in northern Europe. Budé was secretary to Louis XII., whose main interests were in Italy; Lambin visited Rome and Venice before he became the editor of Horace, of Lucretius, and of Cicero; while Muret, though born near Limoges, lived and worked at Rome from 1559 to his death in 1585, and at Rome he lodged for two years the young Joseph Scaliger, destined to become the foremost of European scholars. Italian by descent, but born in France, where he edited his *Manilius* and wrote his *De Emendatione Temporum*, the first great work in historical criticism, he was led by his conversion to Protestantism eventually to retire from France to Leyden, where he ended his days, the dictator of the world of letters. Isaac Casaubon, a leader in exegesis, as Scaliger was in criticism, though born at Geneva, was the son of a French Huguenot refugee, and in France he lived during the greater part of his life, till like Scaliger he found a securer home elsewhere—in Protestant England. Justus Lipsius, the third great scholar of the day, was a Belgian, professor successively at Jena, at Leyden, and at Louvain; he also had travelled in Italy.

Of the members of the older German school the most famous was Erasmus, by birth a Hollander, but the centre of a band of able scholars at Basel, where he spent the last sixteen years of his life, well known in England, and for a short time a professor at Cambridge, a man of vast learning, but not a master in criticism, 'the man of letters, the first who had appeared in Europe since the fall of the Roman empire' (Mark Pattison). He lived some three years in Italy, but gained, as he thought, nothing from it. Able scholars were Camerarius, professor at Leipzig, and Gruter of Antwerp, the first great collector of Greek and Latin inscriptions.

For different reasons France and Germany ceased to be the nurse of scholarship in the 17th century. The reign of Louis XIV. fostered modern rather than ancient literature; and Germany was the scene of furious war. But Scaliger's influence lived on in Holland. At Leyden, where he died, lived Daniel Heinsius and his son Nicolas, Gronow, conspicuous for his skill in appreciating MSS., and Clüwer, the first great writer on geography. At the same time Graefe was editing Cicero at Utrecht. Somewhat later in England lived the first of English scholars, Richard Bentley, in frequent correspondence with Dutch scholars, but owing nothing to them, a man whose astounding critical power could not always save him from errors due to his self-confidence. The only other Englishman whose fame, like Bentley's, has steadily grown with time was Richard Porson, professor of Greek at Cambridge at the end of the 18th century. Distinguished names in the school of Holland in the 18th century are Hemsterhuis and his pupils Ruhnken and Valckenaer. In Germany we find Ernesti at Leipzig, the editor of Cicero; his scholar, Heyne, the founder of the school of Göttingen; Reiske of Leipzig, skilled not only in Greek and Latin, but also in Arabic, whose edition of the Greek orators is still in use; Winckelmann, the first great writer on ancient art; Wolf, professor at Halle, best known as the great Homeric critic, but whose general power and method almost entitle him to a place by the side of Scaliger and Bentley. Scholars of a later date, whose lives extended far into the 19th century, are Immanuel Bekker, professor at Berlin, editor of Plato, Thucydides, the orators, and Aristophanes; Godfrey Hermann, a scholar of unusual breadth, whose fame rests securely upon his work on Æschylus; Welcker, professor at Bonn, the first who combined the study of Greek art, literature, and mythology; K. O. Müller, whose services to the study of ancient history were cut short by his premature death; F. Ritschl, professor at Bonn, the restorer of the text of Plautus, as Lachmann at Berlin was the restorer of Lucretius. We have only of late suffered the loss of H. A. J. Munro of Cambridge, the inheritor of Lachmann's labour on Lucretius; of Madvig the Dane, a Latin scholar of eminent acuteness; and of Cobet, in whom the critical power of Holland seemed to be renewed again. (An excellent sketch of the history of classical philology, by Dr L. von Urlichs of Würzburg, will be found in the first volume of Iwan Müller's *Handbuch der Klassischen Altertumswissenschaft.*)

Speculations on the connection of Greek and Latin—e.g. that Latin was derived from some Greek dialect, and that both, as well as all the other languages of the earth, must be derived from Hebrew—are not wanting in the writings of the older scholars. It was reserved for an Englishman, Sir William Jones, in 1786, to point out that Sanskrit, Zend, Greek, Latin, Gothic, and Celtic belong to the same family; and for Franz Bopp, born at Mainz in 1791, to become the founder of the special science of comparative philology. In his 'conjugation-system,' published at Frankfort in 1816, he worked out the details of the principle already established by tracing out the history of the verb inflections of the Greek, Latin, Old Persian, and Teutonic as compared with Sanskrit. His monumental work, the *Comparative Grammar*, appeared at different times between 1833 and 1852. In this he lays down the phonetic laws of the several languages, and traces their grammatical forms back to their common origin in a lost 'Indo-Germanic' speech. It is impossible here to describe the development of this work in the hands of the singularly able men who laboured at it in the same generation, such as Jakob Grimm, the founder of the scientific study of the Teutonic languages; Pott, the most learned and voluminous of writers; Benfey, the acute philologist and accomplished Sanskritist. The most successful application of the science to Greek was made somewhat later by Georg Curtius, and to Latin by Corssen, and in France by Michel Breal. The common principle of all these writers was that the never-ceasing change in every language is regulated by law; that in each language there is a regular sequence of sound, one passing into the other, not by chance or by the will of any speaker or speakers, but in a definite ascertainable course: and that only by the knowledge of these sequences, commonly but not very wisely termed 'laws,' can the science of language exist. One of the best known of these is the sound-change commonly called 'Grimm's Law,' which states the fact that whenever we find a *k*, *t*, or *p* in Sanskrit, Greek, Latin, and (inferentially) in the common parent-language, we shall find in English and most other Teutonic languages an *h*, *th*, *f*—e.g. *καρδ-ία* (Lat. 'cord-') will appear as 'heart,' 'tres' as 'three,' 'pes' as 'foot;' that *g*, *d*, *b* will appear as *k*, *t*, *p* ('genus' = 'kin,' 'duo' = 'two'); and aspirates (*gh*, *dh*, *bh*) will appear as *g*, *d*, *b* (e.g. Ind.-Ger. 'ghans' = 'goose,' 'bhāgos' = 'beech'). Further, that a subsequent 'shifting' of the same kind, but much less complete, took place many centuries later in Germany itself, and produced there the changes which distinguished the dialects of South Germany ('High') from those of the north ('Low German,' or, as it is called in Germany itself, 'Platt-Deutsch') and from our own English—e.g. 'drei' from 'three,' 'zwei' from 'two,' &c. Such astounding uniformity of change over so large an area was well calculated

to confirm the belief in the 'reign of law' in language. But that belief was certainly strengthened when in 1875 Karl Verner wrote a paper (published in Kuhn's *Zeitschrift*, vol. xxiii.) in which he showed that some apparent exceptions to Grimm's Law were really due to the operation of another and wider law (commonly called by his name) dating from variation of accent preserved by the old Teutonic from the parent-speech; in consequence of which at the present day a west Cumberland dalesman says 'fa*dd*er' and 'mu*dd*er,' but 'bro*th*er,' because in the parent-language (as attested by Sanskrit and Greek) the stress was laid on the last syllable in 'patér,' 'matér,' but on the first syllable in 'bhráter;' and every Englishman says 'lan*d*,' but 'ear*th*' (in the oldest Teutonic 'hlūdá' and 'értha,' with the final vowel still surviving), because the suffix (Ind.-Ger. *-to*) which was common to both was accented in the first word, but not in the last; so also 'min*d*,' but 'grow*th*' (suffix *-ti*), 'floo*d*,' but 'dea*th*' (suffix *-tu*). Here the regularity seems little less than miraculous; and it was discoveries such as this which led about this time to the rise of what is sometimes called the 'new school' of philology, men who in reality only press to their furthest limit the principles of their predecessors. For example, Curtius and Schleicher held that the operation of unvarying law in certain cases did not exclude the possibility of 'sporadic changes'—i.e. of changes found in some words only, not in every word in which the sound so affected occurred: thus, 'lacrima' in Latin shows an *l* instead of the *d* of the original word, as proved by Greek δακρυ and our 'tear;' but they did not therefore think it necessary that every *d* should pass into *l* in Latin.

The 'new school'—Leskien, Brugmann, Osthoff, Paul (to mention a few only of the most conspicuous members)—hold that sound-change so far as it is due to physical causes is absolutely uniform in any one language or dialect at the same time; and that the new form produced by such change in every case drives out the old one. Briefly put, phonetic law is invariable; there is no such thing as sporadic change—change attacking a few words, and sparing others; throughout the whole speech-area all words in which a particular sound occurs are alike affected. This doctrine has commanded very general assent; it is tempting to the scientific mind; and its strength lies in the number of apparent exceptions which have been satisfactorily explained. Yet the *a priori* arguments against it are strong, and it is certain that it is incapable of absolute proof: you cannot prove a negative. But the good done by its supporters in every branch of philology has been immense. They protested, and rightly, against the habit, seen in the later writings of Curtius and other lesser men in other languages, of allowing obvious exceptions to ascertained phonetic law on the ground of identity of function. Be the principle of the new men right or wrong, its observance in practice is excellent. But this protest is only one of the services of the new school. They (especially Paul) have called attention to the inner side of language; the older writers had spent themselves on the outer side. For language is both a physical and a psychical product. The sounds which make language are due to the physical apparatus of speech. As such their nature can be exactly ascertained, and they are subject to changes which can be known and registered like the sequences of any physical science (see PHONETICS), and may be called the outer side of language. The inner development is due to the mind of man; and this, like all the other works of man, belongs to historical and not to physical science. Here the ruling principle is imitation. Every child learns every word it utters through imitation, and imitation of words heard from others or previously uttered by ourselves is the parent of the language of every grown-up man. That we are wholly unconscious of the process does not make the fact any less certain. One form of imitation especially active in speech is what grammarians call 'form-association.' Different forms of speech—e.g. preterite tenses of many verbs, or a particular case of many nouns—are alike each in their grammatical function, and tend to be thought of, and to be used, together. But these forms are nevertheless often very unlike; though their use may be the same they may have different origins—e.g. 'I swam,' 'I stood,' in English owe their distinctive form to a vowel-variation, but 'I heard' to the adding of a suffix. Now, the mind is constantly acting under the influence of analogy to reduce such variations, to do away with unnecessary differences, to reduce old forms to one level, or to make new forms on the analogy of old ones. Thus (see under article GRAMMAR), we now say 'we ran,' not 'we run' as our forefathers did, because the reason for the different vocalism of singular and plural is no longer discernible, and the unmeaning difference is 'levelled.' Again, we say 'I climbed,' not 'I clomb' any more, because the preterite in *-ed* is the simplest and commonest form of the tense, capable of being applied without difficulty when a new verb becomes necessary—e.g. 'we boycotted him.' This principle of 'analogy' (as for brevity it is often called) acts widely in every language; it conditions every new word we make, and it must have acted much more upon vernaculars which had no literature (a good example may be seen in the reconstruction of the old Latin verb in modern Italian), and still more upon wholly unwritten languages.

There are then two chief factors which act on language: one, the *vis inertiæ*, which is the prime cause of phonetic change, and is in the main destructive, doing away with sounds or combinations of sounds which, owing to causes varying with nations and even with individuals, are inconvenient to produce; the other, the imitative habit of mind, which may destroy old forms, but is in the main reparative, giving new forms for those which through phonetic change had become obscure, and constantly producing new forms on the analogy of old ones to supply each want caused by the progress of the human mind. For except in very rare cases man turns old speech-materials to new uses. He does not invent absolutely new names for new things as they become known to him or are produced by him. A hippopotamus was called a 'river-horse;' the trees and beasts of Australia are known by the names of quite different species in Europe. A new invention is called by some descriptive name, as a 'photograph,' which has superseded the older but equally descriptive Talbotype and Daguerreotype: when Talbot and Daguerre were forgotten their names were less suggestive than terms with a meaning. Mesmerism in like manner will be superseded by hypnotism, there being a sufficient number of people able to understand the new name, and so to familiarise it to those to whom it means nothing. Similarly, old names may take a new value, becoming thereby really new words if the connection with the old thing is quite broken off. Thus, a 'bead' to us is a round object made of different materials, absolutely unconnected with the same word in Old English which meant a prayer: the link—counting prayers by means of a string of beads—being no longer a matter of common observation. Sometimes both the old and the new meaning co-exist: a man may be called a 'lion,' but a lion is a lion still. Lastly, new words expressing action—verbs and verbal nouns—constantly spring up, being commonly either more picturesque or giving some

new circumstance. To murder is old, but to 'burke,' a verb coined from a once famous murderer, gives the added sense of smothering and hushing up; and the word seems likely to survive, though with its origin forgotten. To 'boycott' expresses a slightly new form of exclusive dealing, and as yet its history is remembered.

This slight sketch may suffice to throw some light on the nature of language. It is a work of man, the product of man's mind and vocal organs, just as a statue or a picture is the product of his mind and hands. But it differs from them in some important respects. First, it is not a finished product, permanent and unchangeable. It is subject to incessant change, involuntary on its physical side, partly voluntary on the mental side. It is a constant flux, a 'becoming,' not a 'being,' as Plato might have put it; this change is obscured for literary languages; it becomes clear at once to any one who will take the pains of looking at the development of English from Chaucer's day to ours. Old forms die out, and new ones take their place (see GRAMMAR). Old families of words cease to be used: new ones take their place or are produced under new needs—e.g. the Boycott family—boycotted, boycotting, boycotter, boycottee (extinct by this time), &c., all formed on the analogy of the words of other older families. A second point of difference is that language is not an end in itself as a picture is: it exists for an end, communication between man and man. So long as this is achieved the form which language takes is immaterial: it may change so long as it is intelligible. No doubt language once existent can serve other ends more or less connected with the first; but that communication was the first is undeniable.

But language is not the only means by which communication can be made. Animals, which have no language, certainly communicate. Man can communicate by gestures, by pictures—whether rude scratches made on the ground with a stick or the more polished drawings which developed into Egyptian hieroglyphics—or, lastly, by cries common to man and to beasts, the natural expressions of joy, fear, pain, &c. But such cries are not even the elements of language till they are consciously reproduced to express the feeling even when the stimulating cause may be absent. Language itself arises when two men connect the same feeling with the same expression of it, and so can communicate that to others. There is no reason to believe that any brute has ever attained even to the first of these last two steps. Their progress is arrested. A dog may bark to express delight, or to have a door opened to him, but he does no more than any dog could do 2000 years ago. Man can develop. It is not permissible, however, to lay down that the possession of speech is the barrier between man and the brute, and to settle thereby the question of the origin of man. Speech may be the clear differentia now. But it is at least conceivable that there may have been lost types between man and the common progenitor of man and the anthropoid ape with intermediate stages of speech-development. It is another matter to maintain that such development could have been produced by natural selection alone (see Wallace, *Darwinism*, p. 461, ff.).

The different languages of the world can be classified according to their principle of formation; and within the classes so reached different families of languages may be distinguished in which a common origin can be proved for the different languages of each family. Only the briefest sketch can be attempted here. We find two main classes: I. Those languages which show no signs (or hardly any signs) of inflection (see GRAMMAR)—e.g. in which the plural of 'man' is expressed not by vowel-change (as our 'men') nor by an added suffix (as in Latin 'homin-*es*') which has no independent value, but by such a combination as our 'man-kind,' where each part can be used independently. Such languages are the Chinese, the Tibetan, and those of Annam and the neighbouring states; they are commonly called Isolating. II. Those which possess some degree of flection—i.e. elements which have lost their independent meaning, and are mere grammatical machinery to make nouns, as *ter* in 'pa-ter;' or cases of nouns, as *s* in 'father-s;' or persons of verbs, as *s* or *th* in 'gives' or 'giveth.' Such elements, however, are only the worn-out remnants of words compounded with other words (see GRAMMAR); and the languages of this type may vary very much according to the degree of obscuration in the character of the compound. Some, like the Mongolian, the Finnish, the Hungarian, the Turkish, make very long compounds, yet the original elements, though not all capable of separate use, remain quite distinct and recognisable in each word. These languages used to be called 'agglutinative,' as different from the specially 'inflectional' Sanskrit, Latin, &c.; but even these show signs of the phonetic change which produced 'inflections.' The North American languages incorporate different elements which are each barely recognisable in the compound; the principle of composition is not really different. The Dravidian family of languages in South India—Tamil, Telugu, &c.—is also of the agglutinative sort. The languages of the purely inflectional type—i.e. those where the different elements of the original compound are so firmly welded together as to be frequently indistinguishable—are (1.) the Semitic family, comprising Hebrew and the closely-connected Phœnician; Aramaic, spoken in Mesopotamia, Syria, and in later days in Palestine; Arabic; and some Abyssinian languages. This family is remarkable because of its triliteral roots—i.e. expressions of the several ideas by three unchanging consonants, the relation of the various derived forms of the same idea being expressed by vowel-change. (II.) The Indo-Germanic or Aryan family. The first term is most likely to survive; it denotes the extreme limits of the area over which the languages spread—from Sanskrit India to Germanic (or Teutonic) Iceland. The term Aryan has not been adopted much outside of England. The chief languages of this family are (1) Sanskrit, of which the oldest remains are the Vedic hymns, with the cognate Old Persian and Zend, the language of the Avesta. (2) Armenian, as yet imperfectly known, with records dating from the 5th century A.D. (3) Greek, with its numerous dialects. (4) Albanian, proved to belong to this family by Bopp, and lately investigated by G. Meyer and others, but possessing no ancient records. (5) Italic, including Latin, and the Umbrian and Oscan dialects; from these are descended the modern (so-called) Romance languages—the Italian, Spanish, Portuguese, French, Wallachian, and the speech of certain Alpine districts (Grisons, &c.). (6) Celtic, including the ancient speech of Gaul, with its surviving remnant the Bas Breton; the now extinct Cornish; the Welsh, still likely to survive; the Erse of Ireland; the Gaelic of the Highlands of Scotland (the records of these three date from about the 8th century); and the Manx. (7) The Teutonic, now more commonly called Germanic, comprising Gothic, the language into which Ulfilas translated the Gospels in the 4th century A.D.; the Scandinavian, of which a very old form is isolated in Iceland, more modern forms in Norway, Denmark, and Sweden; the Anglo-Saxon; the Old Frisian; the Old Saxon of the 'Heliand,' the parent of the Platt-Deutsch languages of North Germany;

the Lower Franconian, whence comes the Dutch; the Franconian of Mid Germany; and the Old High German, spoken in different dialects from South to Middle Germany, whence is derived the modern literary German. (8) The Slavonic, to which belong Bohemian, Polish, Old Bulgarian, and the parents of the Russian and numerous dialects of south-eastern Europe; together with the Lithuanian, Old Prussian, and Lettish languages of the south Baltic, which, though their records are late, yet preserve strikingly early linguistic features. See ARYAN LANGUAGES.

That there was such a language as the hypothetic parent of all these Aryan languages is certain (though such knowledge brings us no nearer to the one original language—if one there was—spoken by primeval man). We can recover its character with certainty, for we know its suffixes both formative and inflectional; its vocabulary we know in part only. Now, if there was a language there must have been a people to speak that language—no doubt with many dialects, whence eventually sprang the derived languages which we know, and probably many others which are lost. Dialectal variation is the inevitable condition of all languages where there is no common literary tongue: that tends to level the speech of the whole area: and where there is great facility of communication throughout the area the dialects may die out, as they are rapidly doing in England. But though we assert with confidence that there was a common Indo-Germanic language, spoken by an Indo-Germanic people, we do not maintain that the people who speak the several languages derived from that the common parent are wholly of the same race. England, as we know, is inhabited by the descendants of Celts, of various nationalities enrolled in the Roman legions, of Angles, Saxons, Jutes, Frisians, of Norsemen, and of Franco-Normans; all of whom speak the same English language. But that fact does not make us doubt that there was once a common Teutonic language spoken (in various dialects) by the different members of a Teutonic race which occupied Britain. It is extremely probable that there has been a like history in other lands where other Indo-Germanic languages are now spoken. That does not in the least disprove the existence of an Indo-Germanic race, speaking different Indo-Germanic dialects, settling themselves in the different countries of Europe and western Asia, and mixing their blood with that of the races whom they found already there. The proportion of Indo-Germanic blood in any given nation may be considerable: it may be very little. It is possible that in some nations it may be nothing at all: some stronger, but less civilised race may have overpowered the Indo-Germanic stock, but taken their language. Such loss has its parallels in history—e.g. when the Norsemen conquered part of France, but lost their own language. This would explain the fact that races of marked racial difference—with short skulls, and dark hair and colouring—are found speaking cognate languages with men of long skulls, ruddy colour, and light hair. Such an inconsistency has seemed to some anthropologists to absolutely destroy the value of language as a test of race. It does nothing of the kind. Linguistic arguments are as valuable as anthropologic ones: but neither give conclusive proof, only indications. The two sciences should work independently. Good anthropologists, such as Pösche and Penka, may be bad linguists; but results drawn from harmony of the strongest evidence on either side may be fruitful. Most, however, of these problems will probably never admit of certain solution. The evidence which now would place the habitat of the parent-race in northern Europe is only somewhat more weighty than that which formerly placed it in Pamir.

See especially Paul's *Principien der Sprachgeschichte*, translated by Strong (1888); and the *History of Language* (based on the same book), by Strong, Logeman, and Wheeler (1891). Whitney's *Life and Growth of Language* (Inter. Sc. series), Max-Müller's *Essays on the Science of Language*, and Sayce's *Introduction to the Science of Language* are useful; the latter contains a full list of authorities. By far the best book on the history of the Indo-Germanic languages in their earlier stage is Brugmann's *Comparative Grammar* (trans. vol. i. by Wright, vol. ii. by Conway and Rouse, 1888). Here will be found mentioned all the recent works of any importance in this department. A short book referring chiefly to Greek and Latin is Victor Henri's *Précis de Grammaire Comparée* (1888), also translated. For Romance languages the latest and most complete work is Gröber's great *Grundriss der Romanischen Philologie* (Strasburg, 1886–88), in which the different Romance languages are treated by the most competent authorities. Diez's *Grammatik der Romanischen Sprachen*, though somewhat out of date, is clear and good. A similar book on the Germanic languages is Paul's *Grundriss der Germanischen Philologie* (1889 *et seq.*). Special students of English should use Sievers-Cook's *Grammar of Old English* (Ginn, Heath, & Co. 1885), Sweet's *History of English Sounds* (1888), and Skeat's *Principles of English Etymology* (1887 and 1891). For Phonetics, Sweet's *Handbook of Phonetics* should be consulted. All questions on the early history of the Indo-Germanic people and its probable habitat are exhaustively treated in the *Prehistoric Antiquities of the Aryan Peoples* (Schrader-Jevons, 1890). Isaac Taylor's *Origin of the Aryans* (1890) is a useful smaller book on the same subject. The grammars and other works dealing with the modern languages of Europe are too numerous to be mentioned here.

Philomela, according to the Greek legend, was changed into either a swallow or a nightingale. Poets are (or rather were) fond of calling the nightingale by its classic name.

Philopœmen, a patriot of Greece, was born at Megalopolis about 252 B.C. In 222 he was one of the defenders of Megalopolis against Cleomenes, king of Sparta, and next year he fought with the Macedonians against the Spartans. He then served in Crete with such distinction that in 210 he was appointed general of the Achæan horse. In 208 he was raised to the highest military dignity in Greece, being elected *strategos* or commander-in-chief of the Achæan League. The battle of Mantinea (208), in which the Spartans were again utterly routed, raised him to the pinnacle of fame, and at the Nemean festival which followed he was proclaimed liberator of Greece. So great was his influence that the Macedonian monarch, Philip, began to fear that Greece would regain its independence, and tried, vainly, to have him secretly assassinated. During the next few years he was absent in Crete, and returned to the Peloponnesus in 194 to find the Romans in Greece. On the departure of the consul Flamininus, Nabis of Sparta recommenced hostilities against the Achæans; Philopœmen was once more appointed stratēgos (192), and in a pitched battle nearly annihilated the troops of Nabis. He now exerted all his power to heal the divisions among the Achæans, and to prevent them from affording the Romans a pretext for taking away their independence. In 188 he took a fierce revenge on Sparta for having put a number of his friends to death, and was in consequence strongly censured by the Roman senate, and by Q. Cæcilius Metellus, who was sent out as a commissioner to Greece in 185. Two years later Philopœmen (now an old man of seventy) was elected stratēgos for the eighth time. When lying ill of a fever at Argos he rose from his sick-bed to quell the revolt of the Messenians, but was overpowered by numbers, and fell into the hands of Deinocrates, the leader of the Messenians, who two nights after sent him a cup of poison. Philopœmen drank it and died.

Philosopher's Stone. See ALCHEMY.

Philosophy. In a subject where opinion has been and is still so much divided, as is the case in philosophy, it would be vain to attempt to formulate a definition which would be accepted by every one. The objects of the science, its methods, nay, its very possibility, are still matter of debate between divergent schools. The historical method is our only safe guide in such a case; and by its aid we are happily able to fix upon the main elements that were present to the minds of the Greek thinkers who first consciously used the term with a specific meaning. Practically the first attempts at definition are to be found in Plato and Aristotle, and as these two philosophers dominated the human intellect for two thousand years, the ideas which they expressed on the subject inevitably shaped the conception of philosophy current during that time. In virtue of its long lease of life, this conception has established itself in the associations of language, and is vaguely present to the man of ordinary culture when he uses the term. It may claim, therefore, to be the historical sense of the term—the sense, that is to say, which the historian of civilisation would single out as that which has persistently asserted itself during more than two millennia of human progress. Pronounced deviations from the accepted usage occur mainly in connection with a sceptical or quasi-sceptical theory of knowledge, and will be noticed in their place.

Tradition assigns the first employment of the word to Pythagoras, and makes him use it to signify merely the disinterested pursuit of knowledge. Socrates plays upon the etymology of the word when he contrasts the modesty of the truth-seeker with the more arrogant pretensions of the sophists. But, so far, the nature of the truth or knowledge which the philosopher seeks is not specified; the term is still vague and general. In fact, no kind of knowledge was at first alien to the philosopher. Philosophy has been truly called 'the mother of the sciences,' and it was only by slow degrees that the separate sciences attained an independent life. As specialisation proceeded, however, philosophy could no longer *in a literal sense* 'take all knowledge to be her province;' the details of one department after another of existence were surrendered to the scientific specialist. But the claim of philosophy to be the necessary complement of the special sciences—the only science of existence or of the universe as a whole—was not thereby surrendered. The specialist, so far as he is a mere specialist, is like the man who cannot see the wood for the trees; he loses sight of the proportions of the whole in the details of his own province. The co-ordination of the sciences, the unification of knowledge, is a task which remains to be undertaken by the philosopher. Unity or harmony in our conception of the universe is the aim which philosophy always has in view. Whether this aim is attainable by man or not is a further question: but the idea of a system of things satisfactory to the reason and the moral sense remains the inexhaustible spring of philosophic effort. The philosopher, therefore, has always his eye upon the Whole; his true function is to correct the abstractions of the special sciences. Each science makes, and must make, its own working postulates or presuppositions, and the specialist is ever prone to make the working postulates of his own department the measuring-line of existence as such. But philosophy has to review all these scientific postulates, and if possible to harmonise their conflicting claims by showing the relative and limited validity which belongs to each. Philosophy is in this connection the critic of the sciences—of the postulates which they make and the conceptions which they use; and she exercises this critical office in the interest of the Whole. Something like this was present to Plato's mind when he described the philosopher as *sunoptikós*, a man who insists on seeing things together, who refuses to consider the parts out of their relation to the whole whose parts they are, and who is therefore the inexorable foe of crude and premature generalisations from this or the other department of investigation which happens for the time to be most in evidence.

In Plato we find, however, already established a second account of philosophy, which, though unquestionably true in itself, has led, in the opinion of the present writer, to many questionable developments. The philosophers, says Plato, 'are those who are able to grasp the eternal and immutable,' 'those who set their affections on that which in each case really exists.' The philosopher, as the man who apprehends and follows after the essence or reality of things, is thus opposed to the man who dwells in appearances and the shows of sense. This distinction may be said to be implied in the demand for any explanation at all, and is present in Greek philosophy from the beginning. What is the substance or unitary reality underlying all the diversity of the world around us? So ran the question which the early Greek thinkers asked themselves; and the explicit opposition between the world as it *appears* to sense and the world as reason recognises it to *be* had already appeared in the systems (otherwise diametrically opposed) of Parmenides and Heraclitus. In the Platonic doctrine of transcendent Ideas the opposition receives a questionable expression; it appears more legitimately in the Aristotelian doctrine of Substance and Cause. The philosopher, indeed, must always continue to ask himself, What is the essence, the ultimate reality of things? who or what is the Being that is manifested in 'all thinking things, all objects of all thought?' In this sense philosophy is still definable, in Aristotle's phrase, as Ontology, the science of being as being.

To very many, however, in modern times the search for this ultimate reality seems a hopeless quest, and philosophy therefore, in the form of metaphysics or ontology, is condemned by them as a disease of the human spirit, from which, under the influence of scientific habits of thought, it is now happily recovering. The Empiricism which bases itself on Hume, the Positivism which founds on Comte, and various phases of Kantian thought agree in this repudiation of metaphysics. The distinction between phenomena and noumena has been revived in a somewhat different form, and has become current in popular thought. Sensible objects and their laws may be known, it is argued, because in such an investigation we are not carried beyond the facts of present and possible experience; they are phenomena. But if we refuse to take this sensuous phantasmagoria simply as it stands—if we insist on referring it to some ultimate ground of existence as an explanation of why and how there is a phenomenal world at all—the object of our search is variously said to be noumenal, metaphysical, metempirical, or transcendental, and to be unattainable by human reason. To those who hold this view philosophy becomes convertible with Epistemology or Theory of Knowledge (Erkenntniss-theorie). It becomes an 'inquiry into the human understanding,' or a 'criticism' of the forms and categories of human thought, by way of fixing the limits of our necessary ignorance, and thus justifying the negative position assumed towards metaphysics. To Hume and Comte, and to Kant himself in some of his moods, philosophy is thus a preventive against itself, or at least against what has ordinarily

been understood by philosophy. In Hume's words: 'We must submit to this fatigue, in order to live at ease ever after; and must cultivate true metaphysics with some care in order to destroy the false and adulterate.'

This sceptical or positivistic theory, however, is chiefly the result of the unwarrantable separation of essence and appearance, of noumena and phenomena, which has been already referred to as an unfortunate outcome of Plato's way of stating the philosophic problem. If the noumenal reality is something transcendent, something apart from the world we know, and as it were hidden behind it, then it must inevitably drift into the position of a perfectly otiose thing-in-itself, which has no function to discharge in the universe of knowledge. Whether we then continue to assert its existence, as an Unknown and Unknowable, or take up a purely sceptical position in regard to it, is really of little moment. In both cases the limitation of knowledge to phenomena is justified by the false definition of the essence or noumenon from which the theories in question start. But the noumenon is not a transcendent entity apart from the phenomenon: it is simply the phenomenon itself fully understood. To know only phenomena would be to rest content with the immediate appearances of sense. All science is an attempt to go beyond the immediate appearance, and to understand it by connecting it with something else. Ultimately no one thing can be fully understood except in the light of the whole; so to understand things is to reach their metaphysical reality, to see them *sub specie æternitatis*. Following out this line of thought, the modern philosopher oftener gives his question a teleological than an ontological form. Instead of asking what is the ultimate essence, he asks what is the ultimate meaning, the ultimate end, of the universe. Has it a rational and satisfying end? Does it exist to express a meaning at all, or simply as a brute fact? But end, meaning, and ultimate reality are only different ways of formulating the same problem.

But even those modern philosophers who combat most strongly this sceptical view of the inherent impossibility of reaching metaphysical truth agree in laying great stress on what has recently come to be called Epistemology or Theory of Knowledge. The question of knowledge and the relation of knowledge to reality has stood in the foreground of modern philosophy since Locke. It is evidently fundamental and preliminary, for on the trustworthiness of my knowledge and its power of putting me in communication with independent trans-subjective realities depend all my further investigations. If my results in the theory of knowledge are sceptical, I have no foothold in the world of reality to serve as basis for metaphysical construction. The sceptic and positivist therefore stop short at this point; but the philosopher who believes that he has reached a satisfactory doctrine of knowledge (or belief, as he sometimes prefers to call it) advances to metaphysics proper, or the theory of the ultimate nature of the real which he believes himself to apprehend in knowledge.

The general term Philosophy, though occasionally, as has been said, identified with Epistemology, and more frequently with Metaphysics, has in common usage a wider application. Besides these central disciplines it embraces what may be called the philosophical sciences, such as Logic, Ethics, Æsthetics, Psychology, Sociology, the Philosophy of Law, the Philosophy of Religion, and the Philosophy of History. Some of these, however, have two sides, and may be treated either as positive sciences or as parts of philosophy. Psychology, by which is understood what was formerly called Empirical Psychology, may be said to have established its claim to be an independent science of observation and experiment. But, though it may fall more and more into the hands of specialists, it will always remain connected with philosophy, seeing that the knowing mind is the object which the psychologist investigates. Similarly, Ethics is often treated as the natural history of moral ideas and institutions or of the moral sense, but so conceived it really forms a part of scientific psychology. The strictly philosophical part of Ethics is the theory of obligation, and this is sometimes spoken of as the Metaphysic of Ethics. The meaning assigned to duty and the explanation given of it must of necessity profoundly influence the general conception we may form of the universe. So, again, Æsthetics may be treated as a department of physiological psychology, as has mostly been the case in England; but by many continental writers the Philosophy of Art or the Philosophy of the Beautiful has been intimately connected with metaphysics. Jurisprudence on its philosophical side is closely connected with Ethics, and is sometimes spoken of as the Philosophy of Law. The Philosophy of History and the Philosophy of Religion exist only so far as there can be traced in the facts of history and in the different religions of man the evolution of an idea or purpose. Logic, as the science of the regulative laws of thought, forms a part of the general theory of knowledge. It holds aloof, however, from the central question of Epistemology. It presupposes the relation of our thought to reality, but does not itself investigate that relation, confining itself to the laws by which we may validly pass from one statement to another. It occupies a propædentic or introductory position in relation to philosophy, and indeed in relation to scientific thought generally.

The History of Philosophy forms not the least important philosophical discipline. Philosophy cannot, indeed, be profitably studied apart from the history of its own development. Speculative thought has flourished in India and elsewhere, but to all intents and purposes the history of philosophy begins with Thales in Greece about 600 B.C. It is usual to distinguish three great periods of philosophic thought—Ancient or Greek Philosophy, from 600 B.C. to about 500 A.D.; Mediæval Philosophy, lasting till 1600; and Modern Philosophy, since that date. Greek Philosophy is in turn divided into three periods—that of the pre-Socratic philosophers (say 600 to 425 B.C.), who devoted their attention mainly to the phenomena of external nature. Pythagoras, Parmenides, Heraclitus, Empedocles, Democritus, and Anaxagoras were the most eminent heads of mutually conflicting schools. The Sophists and Socrates raised the question of knowledge, turning man's attention upon himself; and in the idealistic systems of Plato and Aristotle (say 400-322 B.C.) we have the great age of Greek philosophy. In Aristotle the theoretic impulse of the Greek mind seems to have exhausted itself, and the post-Aristotelian or third period of Greek philosophy was mainly inspired by practical need, by the desire for a theory of life and conduct. The Stoics, Epicureans, and Sceptics, and later the Neoplatonists with their religious mysticism, carry on the tradition of philosophy till the downfall of the Roman empire and the death of Boethius. After the so-called dark ages Mediæval Philosophy may be said to begin in the 9th century with John Scotus Erigena, who is really a Christian Neoplatonist. Mediæval philosophy is mainly the application of the Aristotelian logic to the doctrines of the church, and latterly (when the other treatises of Aristotle became known in western Europe) exhausted itself in an elaborate attempt to harmonise the philosophy of Aristotle with

Christian theology. Anselm and Abelard in the earlier period, Albertus Magnus, Thomas Aquinas, Duns Scotus, and William of Ockham in the later, are probably the greatest and most representative names of the Scholastic philosophy. The Renaissance put an end to Scholasticism, and led, in the 15th and 16th centuries, to various attempts to revive the systems of the older philosophers and to strike out new paths; but the age was one of transition, and no effective beginning was made in Modern Philosophy till the commencement of the 17th century. Bacon's *Novum Organum* was published in 1620 and Descartes' *Discourse on Method* in 1637. Bacon's investigations were mainly logical and methodological, and Descartes was the real founder of modern philosophy. Cartesianism was developed on the Continent into the great monistic system of Spinoza, from which the monadistic or individualistic theory of Leibnitz was a reaction. In England philosophy took an epistemological and even psychological direction with Locke, and this was continued by Berkeley and Hume, who developed Locke's dualism into subjective idealism and scepticism respectively. Hume's sceptical analysis of knowledge gave rise by revulsion to the Critical philosophy of Kant, which combines elements both from the Continental and the English line of thought. From it sprang the idealistic developments of German thought in Fichte, Schelling, and Hegel, and also the realistic systems of Schopenhauer and Hartmann. Herbart and Lotze represent a realism of a more individualistic cast, which affiliates itself directly to Leibnitz, and is comparatively little influenced by Kantian thought. Scottish philosophy has maintained the reality of knowledge and the dualism of experience in answer to the scepticism of Hume, but like English philosophy generally has been mainly psychological in character. It offers in this way no parallel to the vast metaphysical systems which have succeeded one another in Germany.

The best general histories of philosophy are by Erdmann, Ueberweg, and Schwegler, all accessible in English translations. The greater part of Zeller's exhaustive history of Greek philosophy has also been translated. See also the following articles, and works there cited:

Philostratus OF LEMNOS, a famous Greek sophist and rhetorician, was born probably about 170–180 A.D., studied under Proclus at Athens, and finally established himself at Rome, where he became a member of the learned circle that gathered round the Empress Julia Domna, wife of Severus. He was alive, according to Suidas, in the time of the Emperor Philip (244–249). His extant works are an idealised life of Apollonius of Tyana; the *Imagines*, a description of sixty-four pictures supposed to be hung in a villa near Naples; the *Lives of the Sophists*, a series of bright and interesting sketches; the *Heroicon*, a declamatory exercise on Homer's injustice to Palamedes; and a series of amatory and somewhat strained *Epistles*.

There is a good edition by C. E. Kayser (Zurich, 1844 *et seq.*); an Eng. trans. by E. Berwick (1809). On the question whether the *Imagines* described were real pictures or no, see, for the affirmative, E. Bertrand, *Un Critique d'Art dans l'Antiquité : Philostrate et son École* (1882), and Brunn, *Die Philostratischen Gemälde* (1861); but for the negative, Frederichs, *Die Philostratischen Bilder* (1860).

Philpotts, or PHILLPOTTS, HENRY, was born at Bridgwater, 6th May 1778, studied at Corpus Christi College, Oxford, and was elected Fellow of Magdalen in 1795. He became prebendary of Durham in 1809, Dean of Chester in 1828, and Bishop of Exeter in 1831. A zealous Tory, an extreme High Churchman, and combative by disposition, he was ever the foremost in opposition to measures of reform, and his name would survive if only for his prolonged but unsuccessful refusal to institute Mr Gorham (q.v.) for not believing in baptismal regeneration. Yet if he was narrow he was devoted and sincere, his standard of a bishop's duties was an unusually high one, and he was much beloved throughout his diocese. He died near Torquay, 18th September 1869. See his *Life, Times, and Writings*, by the Rev. R. N. Shutte (vol. i. 1863).

Philtre (Gr. *philtron*, 'love-charm'). A superstitious belief in the efficacy of certain artificial means of inspiring and securing love seems to have been generally prevalent from very early times; and among the Greeks and Romans love-charms, and especially love-potions, were in continual use. It is not certainly known of what these love-potions were composed, but there is no doubt that certain poisonous or deleterious herbs and drugs were among their chief ingredients, to which other substances, animal as well as vegetable, are said to have been added, coupled with the employment of magic rites. Thessaly had the credit of producing the most potent herbs, and her people were notorious as the most skilful practisers of magic arts, whence the well-known 'Thessala philtra' of Juvenal (vi. 610). These potions were violent and dangerous in operation, and their use resulted often in the weakening of the mental powers, madness, and death instead of the purpose for which they were intended. Lucretius is said to have been driven mad by a love-potion, and to have died by his own hand in consequence. In the corrupt and licentious days of the Roman empire the manufacture of love-charms of all kinds seems to have been carried on as a regular trade, the purchasers, if not the makers of them, being chiefly women. The use of philtres seems to have been not unknown during the middle ages; and in the East, the nurse of superstition, belief in the power of love-potions lingers down to the present day.

Phips, or PHIPPS, SIR WILLIAM, governor of Massachusetts, was born at Pemmaquid (Bristol), Maine, on 2d February 1651, one of twenty-one boys in a family of twenty-six children. He was successively a shepherd, a carpenter, and a trader, and in 1687 recovered from a wrecked Spanish ship off the Bahamas bullion, plate, and treasure valued at £300,000; this gained him a knighthood and the appointment of sheriff of New England. In 1690 he captured Port Royal (now Annapolis) in Nova Scotia, but failed in the following year in a naval attack upon Quebec. In 1692, through the influence of Increase Mather (q.v.), he was appointed governor of Massachusetts. He changed the manner of the witchcraft persecutions by appointing a commission of seven magistrates to try all such cases. He died on 18th February 1695 in London, whither he had been summoned to answer certain charges of arbitrary conduct. See Life by F. Bowen in Sparks' *American Biography* (1834–37).

Phiz. See BROWNE (HABLOT K.).

Phlebitis (Gr. *phlebs*, 'a vein'), inflammation of the veins, although seldom an original or *idiopathic* disease, is a frequent sequence of wounds, and is not uncommon after delivery. The disease

is indicated by great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. See VEINS, WOUNDS.

Phlebolites (Gr. *phlebs*, 'a vein,' and *lithos*, 'a stone') are calcareous concretions formed by the degeneration of coagulations in veins, or occasionally originating in the coats of the vessel.

Phlebotomy, or VENESECTION, is, as applied to human beings, treated at BLEEDING, Vol. II. p. 221. The abstraction of blood was at one time considered the best and only remedy for the various diseases of horses and cattle, but at the present time it is comparatively rarely performed, except by veterinarians of the older school; but it is useful in subduing acute congestions, such as of the brain, in parturient apoplexy, congestion of the lungs, acute inflammation of the udder, and in a disease characterised by sudden swelling of the head and throat, called malignant œdema. The vessel selected for the operation is usually the superficial jugular vein, which in cattle is large and loosely situated under the skin of the neck.

In consequence of the mobility of the tissues surrounding the vein it cannot in cattle, as in horses, be raised and made sufficiently tense without the use of a cord tied round the animal's neck below the seat of the intended operation. This cord should be from ¼ to ½ inch thick, pulled tight enough to arrest the flow of blood and cause the vein to become distended and tense. It should then be opened with the 'blood stick,' so as to pierce the skin and vein at one blow.

When a sufficient quantity of blood has been abstracted, say from 3 to 6 or even 8 quarts, the cord is slowly slackened so as to prevent a vacuum and the ingress of air into the vein, the lips of the wound brought into opposition and maintained there by a pin passed through them, and around it twine or tow is twisted in the form of a figure of 8. The pin should not be removed for at least thirty hours.

Phleg'ethon (i.e. 'the Flaming'), a river of the infernal regions, whose waves rolled torrents of fire. Nothing would grow on its scorched and desolate shores. After a course contrary to the Cocytus (q.v.), it discharged itself, like the latter stream, into the Lake of Acheron.

Phleum. See TIMOTHY GRASS.

Phlogiston (Gr., 'combustible') was the term employed by Stahl, professor at Halle, in his *Zymotechnia Fundumentalis* (1697), to designate a hypothetical element which, by combining with a body, rendered it combustible, and which occasioned combustion by its disengagement, there being left, after its evolution, either an acid or an earth. Thus, sulphur, according to the phlogistic theory—which held undivided sway in chemistry until the time of Lavoisier, who substituted for it the theory of oxygenation (1775–81), and was maintained by a few chemists, especially Priestley, till the beginning of the 19th century—was composed of sulphuric acid and phlogiston; lead, of the *calx* or earth of lead and phlogiston; &c. In consequence of the general adoption of the phlogistic theory, when Priestley, in 1774, discovered oxygen, and when Scheele, a little later, discovered chlorine, the names these chemists gave to their discoveries were *dephlogisticated air* and *dephlogisticated marine acid*. According to modern views, mainly based on Lavoisier's experiments, the *addition* of oxygen takes place in the formation of acids and of earths, instead of the *subtraction* of phlogiston. The question whether the process was, in fact, one of addition or subtraction was finally decided by the balance, an instrument to which chemistry owes most of its marvellous progress during the last three-quarters of a century. See CHEMISTRY, Vol. III. p. 146.

Phlox, a genus of plants of the natural order Polemoniaceæ, distinguished by a prismatic calyx, salver-shaped corolla, and unequal filaments. The species are pretty numerous, mostly perennial plants with simple leaves, and mostly natives of North America. A number of species are common in British flower-gardens. It has of late become a favourite genus with florists, and many very fine varieties have been produced.

Phlox paniculata (var.).

Phloxin. See DYEING.

Phocæa, the most northerly of the Ionian cities in Asia Minor, originally a colony from Athens. It stood on a peninsula between the gulfs of Elais and Smyrna, and had an excellent harbour; and the Phocæans were distinguished among the Greeks for their nautical enterprise. When the city was besieged by the Persians in the time of Cyrus, many of its inhabitants emigrated to Corsica; Massilia (Marseilles) was a Phocæan colony. The old city survived into the later empire; its ruins are still known as *Karaulscha Tokia*.

Phocæna. See PORPOISE.

Phocas, a tyrannical emperor of Constantinople (602–610). See BYZANTINE EMPIRE.

Phocidæ. See SEAL.

Phocion (Gr. *Phokiōn*), an Athenian general, was born about the end of the 5th century B.C. He was of humble origin, but studied under Plato, Xenocrates, and perhaps Diogenes also. Phocion first attracted notice in the great sea-fight at Naxos (376), where he commanded a division of the Athenian fleet. In 351, along with Evagoras, he undertook the conquest of Cyprus for the Persian monarch, Artaxerxes III., and was completely successful. In 341 he was successful in crushing the Macedonian party in Eubœa and in restoring the ascendency of Athens. Two years before this he had achieved a similar result at Megara; and in 340, sent to the aid of the Byzantines against Philip, he forced Philip to abandon the siege, and even to evacuate the Chersonesus. Nevertheless, he advocated, even in the midst of his triumphs, the establishment of better relations with the enemy, for he had come under the influence of the philosophical reaction in favour of monarchy instead of a democracy of petty aims and degraded character. He had come to see that a voluntary acquiescence in the supremacy of an enlightened ruler was better for Athens and for Greece than a hopeless struggle in defence of a political system that had lost its virtue. His advice was not taken; but the fatal battle of Chæronea, only two years afterwards, in which the independence of the Greek republics was lost for ever, proved its soundness. After the murder of Philip in 336 we see him struggling at Athens to repress what appeared to him the reckless desire for war on the part of the fanatical patriots, on account of which he was regarded as a traitor; but his personal honour is above suspicion. On the death of Alexander in 323

the aged Phocion endeavoured, but in vain, to hinder the Athenians from going to war with Antipater. After Antipater's death he was involved in the intrigues of Cassander, the rival of Polysperchon, and was forced to flee to Phocis, where Polysperchon delivered him up to the Athenians. He was condemned by 'a mixed mob of disfranchised citizens, foreigners, and slaves' to drink hemlock. His body, flung unburied over the borders of the state, was carried by some of his friends to Eleusis, and burned there. The Athenians soon began to raise monuments to his memory. His life was written by Plutarch and Cornelius Nepos. See *Phocion und seine neueren Beurtheiler*, by Jacob Bernays (1881).

Phocis, a province of ancient Greece, west of Bœotia, and bounded S. by the Gulf of Corinth. The greater part of the country is occupied by the mountain-range of Parnassus (q.v.). The state derives its chief historical importance from possessing the famous oracle of Delphi (q.v.). During the Peloponnesian war the Phocians were close allies of the Athenians. In the time of Philip of Macedon they were involved in a ten years' war, on account of their opposition to a decree of the Amphictyonic Council, concerning the use of a piece of land belonging to the temple of Delphi. This war, commonly known as the Sacred or Phocian War, ended disastrously for the Phocians, the whole of whose cities (twenty-two in number) were destroyed, with one exception, and the inhabitants parcelled out among the hamlets. Phocis and Phthiotis form a province of modern Greece.

Phœbus (i.e. 'the Bright'), an epithet, and subsequently a name, of Apollo. It had reference both to the youthful beauty of the god and to the radiance of the sun, when, latterly, Apollo became identified with Helios, the sun-god.

Phœnicia, the Φοινίκη of the Greeks, the *Phœnice*, or (in rare cases) *Phœnicia* of the Romans, was a tract of country, lying to the north of Palestine, along the coast of the Mediterranean Sea, bounded by that sea westwards, and eastwards extending to the mountain-crests of Bargylus and Lebanon. The limits of the tract northward and southward are variously stated by ancient authorities, and no doubt varied at different periods; but modern researches seem to indicate that the actual Phœnician occupation did not extend beyond Laodicea (Latakia) on the north and Acre, or at the furthest Carmel, on the south. This would give the coast-line a length of about 200, or, counting main indentations, of 230 miles—a fair mean between the 120 miles of Mr Grote (*History of Greece*, vol. iii. p. 354) and the 300 of some writers. The width between the coast and the mountain-ridges of Bargylus and Lebanon varies from 8 or 10 to 25 or 30 miles, perhaps averaging 15 miles. The area of Phœnicia proper may thus be reckoned at about 3000 sq. m. The tract included within these limits is one of a remarkably diversified character. Lofty mountain, steep wooded hill, chalky slope, rich alluvial plain, and sandy shore succeed each other, each having its own charm, which is enhanced by contrast. The sand is confined to a comparatively narrow strip along the seacoast, and to the sites of ancient harbours now filled up. It is exceedingly fine and of excellent siliceous quality, especially in the vicinity of Sidon and at the foot of Mount Carmel. The most remarkable plains are those of Acre, Tyre, Sidon, Beyrout, and Marathus—none of them very extensive, but richly fertile, and capable of producing, under any tolerable system of cultivation, luxuriant crops. From the edges of the plains, and sometimes from the very shore of the sea, rise up chalky slopes or steep rounded hills, which at the present day are partly left to nature and covered with trees and shrubs, partly cultivated and studded with villages. The hilly region forms generally an intermediate tract between the high mountains and the plains; but not unfrequently it commences at the water's edge, and fills with its undulations the entire space, leaving not even a strip of lowland. This is especially the case in the central region between Beyrout and Arka, opposite the highest portion of the Lebanon; and again in the north, between Cape Possidi and Jebili, opposite the more northern part of Bargylus. The hilly region in these places is a broad tract of alternate wooded heights and deep romantic valleys, with streams murmuring amid their shades. Sometimes the hills are cultivated in terraces, on which grow vines and olives, but more often they remain in their pristine condition, clothed with masses of tangled underwood.

Copyright 1891 in U.S. by J. B. Lippincott Company.

From the hilly tract, which increases in elevation as it recedes from the shore, rise the two great mountain-regions, separated by a clearly-marked depression in 34° 35′ lat. nearly, down which runs the river Eleutherus. The more northern of the two was known to the ancients as Bargylus, and in modern geography bears the name of the Ansayrieh or Nasariyeh mountain-region. It extends from the Orontes near Antioch to the valley of the Eleutherus, a distance of not less than 100 miles, looking down eastward on the lower Cœle-Syrian valley, and westward on the undulating tract known as 'Northern Phœnicia.' Though not comparable to Lebanon, it is a romantic and picturesque region. The lower spurs towards the west are clothed with olive-grounds and vineyards, or covered with myrtles and rhododendrons; between them are broad open valleys, productive of tobacco and corn. Higher up the scenery becomes wild and bold; forests of fir and pine abound, and creep up the mountain-side, in places almost to the summit; while here and there bare masses of rock protrude themselves, and crag and cliff rise into the clouds that hang about the loftiest summits. But the glory of Phœnicia is Lebanon. Extended in a continuous line for a distance of 130 miles, with an average elevation of from 6000 to 8000 feet, and steepest on its eastern side, it formed a wall against which the waves of eastern invasion naturally broke. The flood of conquest swept along its eastern flank, down the broad vale of the Buka'a, and then over the hills of Galilee; but its frowning precipices and its lofty crest deterred or baffled the invader, and the smiling region between its summit and the Mediterranean was, in the early times at any rate, but rarely traversed by a hostile army. This western region it was which held those inexhaustible stores of forest trees that supplied Phœnicia with her warships and her immense commercial navy; here were the most productive valleys, the vineyards and the olive-grounds; and here, too, were the streams and rills, the dashing cascades, the lovely dells, the deep gorges, and the magnificent cedar-trees which gave her the palm over all the surrounding countries for variety of picturesque scenery. The principal rivers of Phœnicia were, in the north, the Badas or Nahr-el-Melk, 6 miles south of Jebili; the Nahr Amrith, a strong-running stream which reaches the sea a few miles south of Tortosa (Antaradus); the Nahr Kublé, which joins the Nahr Amrith near its mouth; and the Eleutherus or Nahr-el-Kebir, which reaches the sea a little north of Arka. In the central region are the Nahr-el-Berid or river of Orthosia; the Kadisha or river of Tripolis; the Ibrahim or Adonis; the Nahr-el-Kelb or Lycus; the river of Beyrout or

Magoras; and the Damour or Tamyras. Finally, towards the south are the Nahr-el-Auly or Bostrenus; the river of Sidon; the Litany or river of Tyre; the Zaherany or river of Sarepta; and the Belus or river of Acre (Akko). These rivers, except the Litany, rise from the western flank of the mountain-chains near their crest, and run in deep-wooded valleys, at right angles to the axis of the chains, which is from north to south, having short courses, but conveying generally a good body of water. The Litany alone has its source on the eastern flank of the mountains, and, running down the Cœle-Syrian valley between Lebanon and Anti-Libanus for a distance of 60 miles, turns suddenly to the west, and passes by a deep gorge through the roots of Lebanon to the sea. The Phœnician seacoast is but slightly indented, and possesses but few prominent headlands. The most important are Carmel, if that may be reckoned to Phœnicia; the Ras-el-Abiad, 10 miles south of Tyre; the Ras-el-Jajunieh, a little north of Sidon; the Beyrout promontory; and in the north Cape Possidi. Natural harbours were wanting, except where littoral islands offered a protection from the prevalent winds, as at Tyre and Aradus; elsewhere nature provided nothing better than open roadsteads; and the famous harbours of the Phœnicians were all of them the work of art.

The geology of Phœnicia is tolerably simple. Both Bargylus and Lebanon are longitudinal ranges of the early cretaceous limestone, a limestone that is soft and pliable, very easily worked, but wanting the qualities needed for the imitative arts. This simple formation is, however, intruded upon by disturbances of igneous origin, especially in the lower ridges. 'Down many of the valleys run long streams of trap or basalt; occasionally there are dykes of porphyry and greenstone, and then patches of sandstone, before the limestone and flint recur' (Tristram, *Land of Israel*, p. 634). Some slopes are composed entirely of soft sandstone; many patches are of a hard metallic-sounding trap or porphyry; but the predominant formation is a greasy or powdery limestone, and this is the sole material of the higher ranges. The softness of the general material facilitates the formation of a rapid vegetation and the accumulation of vegetable soil, which, washed down by the rivers, covers the more open valleys and the plains which fringe the coast with an alluvium of the most productive character. Its mountain-regions must always have furnished Phœnicia with an inexhaustible supply of excellent timber—fir, pine, and cedar; the lower slopes of its hills were admirably adapted for the cultivation of the olive and the vine, while its maritime plains were equally fitted for the growth of corn and of almost every kind of fruit and vegetable. In mineral products it may have been deficient; but the sandstone of the Lebanon is often largely impregnated with iron, and some strata towards the southern end of the mountain are said to produce as much as 90 per cent. of pure iron ore. An ochreous earth is also found in the hills above Beyrout, which gives from 50 to 60 per cent. of metal. Coal, too, has been found in the same locality. Finally, the geologist Fraas has recently discovered innumerable traces of amber-digging on the Phœnician coast; whence it may be gathered that rare substances were also in the early times among Phœnician products.

Race and Language.—The Phœnicians have been regarded by some as a nation of Hamitic origin, akin to the Egyptians, chiefly on the ground that Sidon is made a descendant of Ham in the tenth chapter of Genesis (verses 6 and 15). But the evidence of language, of physical type, and of mental characteristics far outweighs this argument, which assumes that Genesis x. is framed on strict ethnographic lines, which is disputable. Hence there is a very general, if not a universal, agreement among the more recent ethnologists that the Phœnicians belonged to the Semitic group (Deutsch, Renan, Socin, Levy, Schröder, &c.). Unless historical grounds can be shown for the belief that a nation at some period of its existence changed its language, the form and type of its speech must be regarded as determining, almost beyond a doubt, its ethnography. Now the Semitic character of the Phœnician language is indisputable. It is so closely akin to Hebrew that a moderate Hebrew scholar can understand it without difficulty. Gesenius first, and since his time Schröder and Renan, having subjected the extant remains to the most searching analysis, have satisfactorily shown, not only that Phœnician is predominantly and essentially Semitic, but that it contains no trace in it of any non-Semitic form of speech. Next to Hebrew, its relations are most close with the Assyro-Babylonian form of the Semitic.

Religion.—The Phœnicians were a people in whose minds religion and religious ideas occupied a very prominent place. In all their cities the temple was the centre of attraction, and the piety of the citizens adorned every temple with abundant and costly offerings. The monarchs who were at the head of the various states showed the greatest zeal in continually maintaining the honour of the gods, repaired and beautified the sacred buildings, and occasionally added to their kingly dignity the highly esteemed office of high-priest (Menand. Ephes. Fr. 1). The coinage of the country bore religious emblems, and proclaimed the fact that the cities regarded themselves as under the protection of this or that deity. Both the kings and their subjects commonly bore religious names—names which designated them as the worshippers, or placed them under the tutelage, of some god or goddess. Abd-alonim, Abd-astartus, Abd-osiris, Abdi-milkut, Abd-esmun are names of the former kind; Abi-baal ('Baal is my father'), Itho-bal ('With him is Baal'), Baleazar ('Baal protects'), names of the latter. The Phœnician ships carried images of the gods in the place of figureheads (Herod. iii. 37). Wherever the Phœnicians went they bore with them their religion and their worship; in each colony they planted a temple or temples, and everywhere throughout their wide dominion the same gods were worshipped with the same rites and with the same observances. But, while we have ample evidence of the religiousness of the Phœnicians, the distinctive character of their religion still remains a matter of controversy. This arises, on the one hand, from the scantiness, jejuneness, and almost stereotyped character of the native notices, and, on the other, from the distorted and misleading account of the religion which has come down to us from a Hellenised Phœnician of the first or second century after our era, Philo of Byblus. A tendency has recently shown itself to 'rehabilitate' this writer, from whose work, disfigured as it is by his euhemerism, much more, we are told, may be gathered than some have supposed, if we only read it rightly. But it is exactly this necessity of reading into Philo what is not there that makes reliance on him as an authority unsafe. It is only when corroborated by other writers, or by the native remains, that Philo's statements have any value. The native remains show us that in the later historical times, for which alone they exist in any abundance, the Phœnician religion was a polytheistic nature-worship of a somewhat narrow character. There is reason to believe that, like so many other polytheisms, it had an earlier monotheistic stage. Of this stage

the names Baal, El, El-Elioun, Rimmon, Molech, Adonai are traces (Max-Müller, *Science of Religion*, p. 177 *et seq.*). Another trace is found in the quasi-universality of Baal and Ashtoreth, names which may be applied respectively to any god or any goddess. But the monotheistic stage passed away at a very early date, and a manifest polytheism succeeded it—a polytheism in which various gods and goddesses (*alonim v' alonuth*) were recognised by every worshipper, as by the Carthaginian introduced into his play of the *Pœnuli* by Plautus (v. 1, line 1).

Of these gods the most prominent, besides Baal and Ashtoreth, were Melkarth, the special god of Tyre; Adonis, the god of Byblus; Sydyk; Dagon; Eshmun, with his brothers, the seven Cabiri; and Molech. Minor deities were Zephon, Tsad, Sakon, Aziz, and Pa'am. In the decline of the nation there was a marked tendency to add to the Pantheon by the introduction of foreign deities, as Ammon, Osiris, Phthah or Ptah, Pasht, and Athor from Egypt, Tanata from Syria, Nergal from Assyria, and perhaps others. The notices are too scanty to enable us to trace out in any detail the nature-worship connected with this polytheistic system, but it is certain that Baal and Ashtoreth represented, to a large extent, the sun and moon, while Dagon was a corn-god, Eshmun a hunter-god, Aziz probably a war-god, and the Cabiri artificer-gods, especially connected with ships and navigation. The gods were worshipped with perpetual sacrifice in their temples, with votive offerings and with festivals. A spring festival to Melkarth, 'the Baal of Tyre,' in the month Peritius (Joseph. *Ant. Jud.* viii. 9, sect. 3), and another to Ashtoreth called 'the brand-feast' (Lucian, *De Dea Syra*, sect. 10), are especially noticed. Anciently it was not considered right to erect statues to the gods in their temples; but the practice was to represent them by conical pillars of stone or wood (Tacit. *Hist.* ii. 3). Two terrible rites particularly characterised the religion—human sacrifice and religious prostitution. A divine original was found for the former of these, El having in a time of great danger immolated his only son upon an altar to avert the evil wherewith the land was threatened. Henceforth such sacrifices were from time to time offered by the state when great disasters seemed impending, and individuals appeased the divine anger against themselves by the offering of their children. At Carthage, we are told (Diod. Sic. xx. 14), an image of El, made of metal, was heated to a glow by a fire kindled within it, and the victims, deposited by their parents in its arms, thence rolled into the fiery lap below. First-born, and especially only sons, or virgin daughters, were deemed peculiarly acceptable to the divinities. The godhead, it was thought, demanded the holiest and most costly gifts possible; and this idea, which lay at the root of the child-sacrifice, may be regarded as also explaining the prostitution of virgins in the temples and groves of the 'Queen of Heaven,' which was certainly an established custom (Luc. *De Dea Syra*, sect. 6; Euseb. *Vit. Constant. Mag.* iii. 55, sect. 3). The institution of the Galli carried out the same idea, and added a final degradation to a system otherwise sufficiently revolting.

Manufactures and Inventions.—Two inventions connected with manufactures were especially claimed by the Phœnicians—the invention of glass, and the discovery of the purple dye. Glass is said to have been discovered accidently on the Phœnician coast (see GLASS); but as the Egyptians had manufactured glass for many centuries before the Phœnicians occupied the Mediterranean coast, and as there was a very early trade between Phœnicia and Egypt, it is most probable that the Phœnicians borrowed their glass-making from the Egyptians. What was special to Phœnicia in respect of glass was the excellent quality of the siliceous sand near Sidon and in the Bay of Acre. Their glass was of three kinds, transparent colourless glass, translucent coloured glass, and opaque coloured glass, scarcely distinguishable from porcelain. The first they used chiefly for mirrors (Plin. *Hist. Nat.* xxxvi. 26); the second for beads, for imitations of gems, and for bottles, jugs, vases, and amphoræ, which are often of extraordinary beauty. Opaque glass was employed in statues and statuettes. The Phœnician purple dye was derived, principally if not entirely, from two shell-fish which were abundant in the Eastern Mediterranean, the *Murex trunculus* and the *Murex brandaris*. From these, by careful treatment, a number of tints, varying from blue, through violet and purple, to crimson and rose, were produced, and, by different processes, rendered at once brilliant and permanent. With the purple-dye manufacture was closely connected the manufacture of textile fabrics, wherein the Phœnicians appear to have excelled. 'White wool' from Syria (Ezek. xxvii. 18) and Arabia (*ibid.* ver. 21), flax from Egypt, and silk from Persia furnished the materials which were worked into stuffs of excellent quality by the Tyrian and Sidonian artisans, who, partly by the brilliancy of their dyes, partly by their skill in embroidery, obtained for those stuffs a precedence over the products of the looms of Egypt and Babylon. Phœnicia also manufactured on a large scale all manner of household utensils and implements, partly in clay, partly in metal, together with ornaments of various kinds, for the purposes of the export trade which she carried on with barbarous and semi-civilised countries.

Navigation, Trade, and Colonies.—The Phœnicians appear as navigators in the earliest Greek (Hom. *Od.* xv. 415–484), and in some of the earliest Hebrew (2 Chron. ii. 16) notices. They were regarded as familiar with the sea in times anterior to the Trojan war (Herod. i. 1). At first, no doubt, their navigation was timid and cautious. But after a time they became bolder. They sailed direct from headland to headland, and from their own coast to Cyprus, a distance of 70 miles; they continued their voyages during the night, and after a while adventured themselves in the open sea, directing their course by the Polar star, which they found to mark approximately the true north in the seas to which they had access. Their ships, though small, according to our ideas, were well built, and admirably fitted up and arranged (Xen. *Œconom.* sect. 8). For trading purposes they employed ships of a broad, round make (γαῦλοι), but in war they used galleys of a considerable length, which were ordinarily impelled by oars, the rowers sitting on a level, or else in two ranks, one above the other, or sometimes in three. The earliest representations of Phœnician vessels which have come down to us are in the sculptures of Sargon and Sennacherib (*circa* 700 B.C.); those of the latter showing a double tier of rowers. The crews of these vessels do not appear to exceed the number of twenty-five; but the Phœnician war-galleys in the fleet of Xerxes (480 B.C.) carried a crew of 200 sailors, besides thirty men-at-arms (Herod. vii. 184). Phœnician trade was in part a land trade conducted by travelling companies of merchants, in part a traffic by sea. Of the land trade the best account which we possess is that given in the 27th chapter of Ezekiel (verses 13–24), by which it appears that this traffic extended over the greater part of western Asia, including northern Syria, Syria of Damascus, the land of Israel, Arabia, Mesopotamia, Assyria, Babylonia, parts of Armenia, and much of central Asia Minor. Northern Syria furnished the Phœnician merchants

with *butz* (probably cotton), and with embroidery and precious stones. Syria of Damascus gave the 'wine of Helbon' and 'white wool.' Israel supplied corn of a superior quality, called 'corn of Minnith,' together with *pannag*, an unknown substance, honey, balm, and oil. Arabia provided spices, as cassia, and calamus or aromatic seed, together with frankincense, and perhaps cinnamon and ladanum. She also supplied wool and goats' hair, cloths for chariots, gold, wrought-iron, and precious stones, together with ivory and ebony, which she probably imported from Abyssinia. Babylonia and Assyria furnished wrappings of blue, embroidered work, and chests of rich apparel. Upper Mesopotamia partook in this traffic. Central Asia Minor, the home of Tubal and Meshech, supplied slaves and vessels of brass. Armenia gave horses and mules of a superior quality. There may have been some further land traffic with Egypt, since the Phœnicians had a settlement at Memphis (Herod. ii. 112), with Persia for silk, and with Central Africa for slaves and skins.

But the land trade of Phœnicia, extensive as we have shown it to have been, was eclipsed by its maritime commerce. The Phœnicians had, in the early times, the command of the entire Mediterranean, of the Propontis, and of the Euxine. They traded largely with the Greeks (Herod. i. 1) and with the natives of almost the entire coast tract between Colchis and the Pillars of Hercules. It was in connection with this maritime trade that they sent out the great bulk of their colonies. Cyprus seems to have been first occupied, then Cilicia, Lycia, Rhodes, Crete, and the Cyclades and Sporades. From these islands the advance was easy to those of the Northern Ægean, Lemnos, Imbros, Thasos, and Samothrace. Then the coast of Thrace was colonised, the Propontis was entered, and a few settlements were perhaps made on the southern coast of the Black Sea. In the opposite direction an advance was made from Crete and Cythera towards the west. The shores of Sicily were occupied, together with the littoral islands and the opposite shores of Africa. Utica, the first African colony, was followed quickly by Hippo Zaritis, Hippo Regius, Hadrumetum, Leptis Major, Leptis Minor, Thapsus, and ultimately by Carthage. The Balearic Islands and the southern parts of Sardinia were soon afterwards occupied, and finally southern Spain and the western coast of Africa, as far as Cape Nun, opposite the Canary Islands. But Phœnician trade far outran Phœnician colonisation. From Tartessus in Spain, outside the Straits, the Atlantic and Bay of Biscay were explored, a trade with Cornwall and the Scilly Islands was established, and the Baltic possibly was entered in the search for amber. North-western Europe was laid under contribution to increase the wealth of the small group of states on the Syrian coast; and at the same time from Lixus, and later from Carthage, western Africa was visited, and a *dumb* commerce established with the natives of the parts about the Senegal and Gambia. Towards the east, moreover, Phœnicia at one time held a share in the trade of the Red Sea (1 Kings, ix. 26–28), sent her ships into the Indian Ocean, and perhaps pushed her commerce as far as Malabar and Ceylon. As a general rule, she imported raw materials, and exported manufactured articles; but there were exceptions to this rule; and, to some extent, she employed herself in a carrying trade, being the negotiator between the east and west, introducing into Greece the finished productions of Egypt and Assyria, of Babylon and Hindustan, while she conveyed to those countries Greek pottery and Greek works of art, Greek wine, and Greek musical instruments.

Art and Literature.—Phœnician art is wanting in originality, but it is not without a certain amount of merit. In the earlier times Egypt and Assyria, in the later Greece, furnished the 'motives,' at once of the architecture, and of the decorative art of the country. Massiveness, heaviness, and a sparing use of ornament characterise the architecture, or, at any rate, its extant remains, which are chiefly walls, tombs, and sepulchral monuments. The walls of Aradus and Sidon are built of blocks almost equal in size to those of the pyramids. Pyramidal forms occur in the sepulchral monuments, though simple pyramids were not affected. No considerable remains of any temple or palace have as yet been found, and it is doubted whether the so-called temples were not rather small shrines or cells placed within a peribolus, adorned with trees, fountains, walks, colonnades, and cloisters. Such a shrine still exists near Amrith (Marathus), and is known as the 'Maabed,' or 'Temple.' It stands in the middle of an excavated court, and rises to the height of 27 feet. Its only ornaments are a cornice and string-course (Renan, *Mission de Phénicie*, pp. 62–68). An erection of more pretension and considerably greater merit, situated near the same place, bears the name of *meghuzil*, 'spindle,' and is much admired by some moderns. M. Renan calls it 'a real masterpiece in respect of proportion, of elegance, and of majesty' (*ibid.* p. 72). It is, however, no more than 32 feet in height, and, though in good taste, implies but little architectural skill—much less any grandeur of conception. The tombs attached to the monuments are sepulchral chambers of some size, but without ornament. They generally contain either niches for the reception of corpses or sarcophagi. The sarcophagi are in some cases of a highly ornamental character, having elaborate reliefs both on their sides and ends. Two found by General Cesnola in Cyprus, and one discovered near Sidon, are especially interesting. The reliefs on these tombs are decidedly superior to the statuary, which is rude, coarse, and wanting both in tone and elegance. Phœnician art culminates in the embossed metal pateræ which have been found in so many places, sometimes with Phœnician inscriptions, and always in an unmistakable Phœnician style (Perrot and Chipiez, *Histoire de l'Art dans l'Antiquité*, vol. iii. pp. 759–789; Eng. trans. 2 vols. 1885). The representations on these pateræ have abundant life and spirit.

The subject of Phœnician literature introduces us to the vexed question of the origin of the Phœnician alphabet, and the amount of credit due to the people for inventing it. The time is long past for echoing the opinion of the Greeks, and regarding the Phœnicians as the original inventors of letters. The hieroglyphical writing of the Egyptians, several of the cuneiform syllabaries, and the script of the Hittites are all of them much more ancient than the earliest Phœnician writing, and must have been more or less known to the Phœnicians before they hit upon their own system. Their alphabet, no doubt, like all others of which we have any knowledge, originated in a picture-writing, but whether their characters were modifications of the Egyptian, or of the Hittite, or of the Cypriot, or were abbreviated forms of a picture-writing peculiar to themselves, will probably never be settled. (For the view that the Phœnician letters are derived from the Egyptian hieroglyphics, see ALPHABET, Vol. I. pp. 185–188, where the forms of the Phœnician letters are shown.) The only merit which they can claim, as inventors or improvers of writing, is that of simplification. They discarded the surplus signs with which other nations had encumbered themselves, as determinatives, ideographs, and the

like; they assigned to each character a single definite articulation, and to each articulation a single definite character. They thus got rid of the immense multiplicity of earlier systems, and invented an alphabet the value of which was so transcendant that it has maintained itself ever since, and among civilised nations has superseded every other, having only received certain slight modifications. Their alphabet was invented by the Phœnicians for business purposes, which required despatch; and it was employed almost wholly for business purposes until a comparatively late date. The Phœnicians proper, so long as they remained a nation, scarcely possessed anything that we should call a literature. They employed writing for short inscriptions on votive offerings, on tombs, and on coins, for curt records of the history of their country, or rather of their several towns, and no doubt for commercial transactions, but they scarcely wrote books or indulged in what we understand by the art of composition. One work on a philosophic subject (the atomic theory) is assigned to Mochus, a Sidonian (Posid. ap. Strab. xvii. 2, sect. 22), and one on religion, or rather on cosmogony, almost certainly apocryphal, to Sanchuniathon, a Berytian. But otherwise Phœnician literature belongs, not to Asia, but to Africa. The fragment of the *Periplus* of Hanno (q.v.), which has come down to us in a Greek dress, shows that the Liby-Phœnicians at any rate could write interesting books of travels; and the Latin writers speak highly of Hiempsal, Mago, Hamilcar, and others, who had composed valuable works upon the history, geography, and 'origines' of Africa, and also upon practical agriculture (Sallust. *B. J.* sect. 17; Cic. *De Orat.* i. 58; Amm. Marc. xxii. 15; Solin. *Polyhist.* sect. 34).

Origin and History.—Two accounts have come down to us of the origin of the Phœnicians. According to Herodotus, Strabo, Pliny, and others, they dwelt anciently on the shores of the Persian Gulf (Erythræan Sea), whence they crossed by land to Syria, and settled on the coast of the Mediterranean. Herodotus (vii. 89) declares this to be their own account of themselves, and Strabo says that there was a similar tradition among the inhabitants of the gulf, who showed, in proof of it, Phœnician temples on some of the islands. Justin, on the contrary, in his epitome of Trogus Pompeius, declares that they were driven out of their country by an earthquake, and passed to the Mediterranean from the 'Syrian lake,' or Dead Sea. This latter version of the story has been connected by some with the destruction of the Cities of the Plain recorded in Genesis. Whichever account be preferred, it would seem that the Phœnicians regarded themselves as immigrants into their country, and not (like most ancient nations) as aboriginals. The settlements upon the Mediterranean coast were no doubt made by degrees, and the settlers at different places were, from the first, independent of each other. Among the earliest of the sites occupied were those of Sidon, Arka, Aradus, and Simyra (Gen. x. 15–18). Tyre was not settled till considerably later, and Tripolis was a colony from Tyre, Sidon, and Aradus. Gebal, Akko (Acre), Berytus (Beyrout), and Sarepta are mentioned, together with Tyre, in Egyptian inscriptions of the 14th century B.C. (*Records of the Past*, vol. ii. pp. 110, 111); and it would seem that from about 1600 to 1300 Phœnicia must have been a dependency of Egypt. But on the decline of Egypt under the twentieth dynasty the flourishing time of Phœnicia began. Sidon especially grew to greatness, and became known as 'Great Sidon' (Josh. xi. 8; xix. 28). Under her hegemony Akko, Achzib, and Aphek were able to resist the conquering Israelites (Judges, i. 31). She even at this time pushed her land dominion as far as Dan or Laish, on the headwaters of the Jordan (*ibid.* xviii. 7, 8). Her vessels traversed the Mediterranean, and she became known to the Greeks as the chief commercial power in the world, and as eminent in various branches of industry. At the same time she began that system of colonisation which Tyre afterwards pursued with so much success. Her emigrants occupied Citium and other places in Cyprus, the Ægean Islands, Malta, Utica, and other sites on the North African coast, together with many points in Sicily. She also endeavoured to extend her influence into Philistia, and, after colonising Dor (Scylax, *Periplus*, sect. 104), made war on Ascalon. Here, however, she received a rebuff. The Philistines under Ascalon attacked her by land, and so pressed the siege that the bulk of the citizens fled from the town by sea, and took refuge at Tyre (Justin. xviii. 3), which may thus have acquired her pre-eminency. Certainly in the second period of Phœnician history (1252 to 877 B.C.) Tyre rather than Sidon takes the lead. The Tyrian colonies of Thasos, Abdera in Thrace, Pronectus in Bithynia, Gades, Malaca, Sexti, Carteia, Belon, and a second Abdera in Spain, Caralis in Sardinia, Hadrumetum, and the lesser Leptis in North Africa, Tingis and Lixus on the West African coast are founded. The new Judæan kingdom established by Saul and ruled by David (*circa* 1050) finds Hiram (Hirôm) of Tyre a powerful neighbour, and enters into friendly relations with him. The friendship continues under Solomon, and both the Hebrew and the Tyrian annals (Dius, Fr. 2; Menand. Fr. 1) mention the communications which took place between them. Hiram gave Solomon timber, and lent him workmen for both his palace and temple, receiving in return large annual payments in corn, wine, and oil, and ultimately obtaining a cession of territory (Cabul), which, however, he did not much value (1 Kings, ix. 10–13). The friendship led on to a participation of Solomon in the Tyrian trade, both with Tarshish, or Tartessus, in Spain (*ibid.* x. 22), and with Ophir, perhaps the coast of Malabar (1 Kings, ix. 26; x. 11). Hiram reigned forty-three years, and greatly beautified and improved his capital, which he enlarged by substructions and by uniting to it a separate island, besides adorning it with new temples, and probably with a new palace. He is thought to have also sent an expedition to Africa, and reduced the people of Utica to subjection. His dynasty is thus given by Menander: Hiram reigned forty-three years, from about 980 to 936. Baleazar, his son, who succeeded him, reigned seven years, from 936 to 929. Abd-Astartus, Hiram's grandson, then succeeded, and reigned nine years, from 929 to 920, when he was murdered by four of his foster-brothers, the eldest of whom took the throne, and reigned twelve years, from 920 to 908. He was succeeded by a monarch of the ancient stock, Astartus, who also reigned twelve years, from 908 to 896. Ascrymus, a brother of Astartus, then mounted the throne, and reigned nine years, from 896 to 887, when he was murdered by another brother, Pheles, who, after a reign of eight months, was in his turn murdered by Ithobal, priest of Ashtoreth, who held the throne for thirty-two years, from 887 to 855. Ithobal appears as Eth-baal, and is called king of Sidon (1 Kings, xvi. 31), since he probably reigned over both cities. He gave his daughter, Jezebel, in marriage to Ahab, and was thus the means of introducing the Baal worship among the Israelites. The foundation of Botrys on the Syrian coast, north of Gebal, and the colonisation of Aüza in Numidia are assigned to him. He was succeeded by his son, Badezor, who reigned six years, from 855 to 849, and then gave place to his son, Mattan,

who reigned nine, or more probably twenty-nine years, from 849 to 820. At his death the crown fell to his son, Pygmalion, a boy of eight or nine years old. A dispute, however, arose about the succession between Pygmalion and his uncle, Sicharbas (married to Pygmalion's sister Elissa or Dido), and the result was Sicharbas' murder, and the flight of Elissa to the North African coast, where she founded Carthage, 814.

A foreign enemy began to threaten Phœnicia in the reign of Ithobal. Earlier Asiatic monarchs, as Chedorlaomer and Tiglath-pileser I., had made no permanent impression on the Syrian region; but from the time of Asshur-nazir-pal (883–860) Assyria began a series of attacks upon all the tribes and nations in these parts, which resulted in their subjugation and submission to the Assyrian yoke. Asshur-nazir-pal, about 877, was the first to cross the Euphrates, enter the Orontes valley, and commence the conquest of the Syrian tribes. He received tribute from the Phœnician cities of Aradus, Gebal, Sidon, and Tyre. His son, Shalmaneser II., completed the reduction of Phœnicia, defeating Mattan-Baal of Aradus, and compelling the other monarchs to a fixed system of tribute. The relations between Assyria and her vassal then continued peaceful for about a century (840–740). Assyria encouraged the Phœnician land traffic, and the Phœnicians gladly paid their tribute and their homage in return for the protection afforded them. But about 740 a new policy was adopted. Tiglath-pileser II. was an active and enterprising prince, who energetically applied himself to the consolidation and unification of the empire. He began the process in northern Syria, rearranging the population in the various towns, taking from some, and giving to others, adding in most places an Assyrian element, appointing Assyrian governors, and requiring of the inhabitants 'the performance of service like the Assyrians' (*Eponym Canon*, p. 120, line 28). Among the places thus treated between 740 and 738 were the Phœnician cities of Simyra and Arka. The result was a general awakening of distrust among the Phœnician populations. Simyra and Arka revolted in 720, in conjunction with Hamath, Arpad, Damascus, and Samaria (*ibid.* p. 126, lines 33–35). Tyre took the alarm even earlier. Under Luliya, or Elulæus, she built herself up a great power, extending her sway over Sidon, Akko, Ecdippa, Sarepta, Hosah, Mahalliba, &c., and at the same time seeking to bring under her yoke the distant island of Cyprus. These movements provoked Assyria to action. About 727 Shalmaneser IV., the successor of Tiglath-pileser II., made an attempt to crush Elulæus from the land side. Baffled in this, he succeeded in detaching from the Tyrian alliance a number of the minor Phœnician towns, and with the help of their fleets assaulted the island Tyre by sea. But the Tyrians defeated his attack, and he was compelled to withdraw and seek to force them to a surrender by cutting off their supplies of water (Menand. Ap. Joseph. *A.J.* ix. 14, sect. 2). But they withstood him for five years, at the end of which the Assyrian monarch lost his throne by a revolution (722), and Tyre was for many years unmolested. At last, however, Sennacherib (*circa* 701) felt strong enough to renew the attack, and, having united against Tyre most of the other southern Phœnician cities, drove Elulæus from his throne, and forced him to take refuge in Cyprus. A tranquil period then set in, but only to be followed by further revolts and subjugations. In 680 Abd-Melkarth, king of Sidon, revolted against Esar-haddon, and was captured and slain. Eight years later, in 672, Baal, king of Tyre, who had taken the place of Abd-Melkarth, joined Tirhakah against his suzerain (*Eponym Canon*, p. 142, lines 12, 13), and was severely punished (*ibid.* pp. 144, 145); and about 645 Hosah and Akko both revolted against Assur-bani-pal, the son of Esar-haddon, and were attacked, conquered, and punished with utter destruction. The Assyrian period, which began so fairly in the 9th century, terminated in the 7th in a series of revolts, sieges, and massacres.

The Assyrian power came practically to an end about 630, and Phœnicia found herself once more independent. Tyre again sprang into notice, occupying the foremost place, and establishing a hegemony over the other cities (Ezek. xxvii. 8–11). But this prosperity and glory were short-lived. Within a brief space Phœnicia, and Syria generally, became a bone of contention between Egypt and Babylon, the two powers which made the earliest efforts to profit by Assyria's fall. First Egypt, under Neco (608), occupied the territory, and then Babylon, under Nebuchadnezzar (605), seized it. Tyre received a grievous blow at the hands of this latter prince, who, after a siege of thirteen years, forced the island city to submit to him. Phœnicia remained a Babylonian dependency from 585 to 538, when Cyrus took Babylon, despite the efforts of the Egyptians to make themselves masters of it. A fragment of Menander gives the internal history of Tyre during this interval. Nebuchadnezzar's opponent, it appears, was a second Ithobal, who reigned from about 597 to 573. He was succeeded by his son, Baal II., who held the throne for ten years, from 573 to 563. A revolution then took place, kings being replaced by 'judges,' officers of an inferior status. Of these, Ecnibaal reigned for two months, Chelbes for ten, and Abbarus for three. The office was then divided, as at Carthage, between two, and Mytgon and Gerastartus held it for six years (562–556). But now another internal struggle took place, and the monarchy was restored in the person of a certain Merbal, who was sent for from Babylon, a descendant of the ancient kings. This prince reigned four years, from 556 to 552, and was succeeded by his son, Hiram II., who had a reign of twenty years, from 552 to 532. It was in this king's reign that the Babylonian empire came to an end, and Phœnicia had another brief interval of independence (538 to 527).

The Babylonian was followed by the Persian period, which lasted from 527 till 333. Phœnicia submitted to Cambyses without a struggle, and became an integral portion of the Persian empire. In the arrangement of the provinces she held a place in the fifth satrapy, which was composed of Syria, Phœnicia, Palestine, and Cyprus. She was allowed, however, to keep her native kings, and to organise for internal purposes a native government. Tyre, Sidon, and Aradus united themselves by federal ties, and sent representatives to a common council, which met at Tripolis. An excellent understanding was for some time maintained between the suzerain power and her feudatory, which zealously supported Persia in her various maritime wars, forming the main element of her naval strength. It was Phœnicia which crushed the Ionian revolt at Ladé (495), which caused the failure of the Athenian expeditions to Egypt (460–455), and which enabled Persia to extort from the Lacedæmonians the peace of Antalcidas (387). A curious feature of this period was the intimacy and friendship established between Phœnicia and Athens, which, feeling that its power of coping with Sparta depended greatly on the support of the Phœnician fleet, gave exceptional privileges to the Phœnician people and states. Phœnicians were allowed to settle in Attica, particularly at Phalerum and the Piræus, to erect tombs there, and have their own places of worship, while ultimately

(about 370) the relation of *proxenia* was entered into between Strato, king of Sidon, and the Athenian people. Towards the later part of the Persian period, however, the allegiance of Phœnicia began to waver. Evagoras of Salamis, when in revolt against Mnemon, is thought to have obtained a certain amount of Phœnician support (Kenrick, *Phœnicia*, p. 405). In the 'War of the Satraps' (366) the defection of Phœnicia from the Persian cause is certain. Later on came the great Phœnician revolt. Encouraged by the successful stand which Nectanebo had made against Ochus, Tennes, king of Sidon—probably the Tabnit of the Sidonian inscriptions—raised (in 351) the standard of rebellion. All the other cities joined him. Alliance was made with Egypt; the Persian garrisons in Phœnicia were massacred, the royal park was plundered, and the stores laid up for the Persian cavalry were destroyed (Diod. Sic. xvi. 41, sect. 5). The first attempt which Persia made to crush the rebellion failed; but in 345 Ochus himself invaded Phœnicia with an army of 330,000 men, and Tennes, regarding resistance as hopeless, submitted, and received the Persians within the walls. But the inhabitants generally refused to submit. Shutting themselves up within their houses, together with their wives and children, they applied the torch to their dwellings, and lighted up a general conflagration. Forty thousand persons are said to have perished in the flames (Diod. Sic. xvi. 45). Tennes, notwithstanding his submission, was executed, and the crown passed to his son Abd-Astartus (Strato II.). The last Sidonian dynasty is traceable for five generations, through the following six sovereigns—Esmunazar I., father of the first Tabnit (*circa* 460–440); Tabnit I., his son, who married his own sister, Am-Ashtoreth; Esmunazar II., their son, whose tomb is in the collection of the Louvre; Strato I., this Esmunazar's brother, who reigned from about 400 to 361, and was *proxenos* of Athens; Tennes II., Strato's son, who reigned from 361 to 345, when he was put to death by Ochus; and Strato II., the son of the second Tabnit, who held the throne from his father's death to the final extinction of Phœnician independence (333) by Alexander.

Alexander's invasion of Asia in 334 found the Phœnicians still attached to Persia. The fleet of Memnon, which commanded the Ægean, consisted principally of Phœnician vessels, the contingent of each state being under the direction of the native monarch, or his son. No sign of disaffection showed itself until the defeat of Darius at Issus (333), when the collapse of the Persian power, and the advance of the Macedonians into Syria in overwhelming force, made a change of policy necessary. Aradus, Byblus (Gebal), and Sidon then surrendered themselves; and Tyre would have done the same had not Alexander made the unpalatable demand that he should be received into the island-city. Upon this the Tyrians resolved to defy him, and, under their king, Azemilcus, stood the famous siege, which is perhaps the most glorious event in Phœnician history. It was not till all their sister-cities had deserted them, and the Macedonian monarch had filled up the strait between the mainland and their isle, that they were conquered. Then at last the brave and tenacious people succumbed to destiny, and, losing their nationality, became absorbed into the Greco-Macedonian empire.

No native history of Phœnicia has come down to us, and it is questionable whether any such history was ever written. The so-called 'Phœnician History' of Philo Byblius, ascribed by him to Sanchoniathon, is not historical but mythological. Phœnician history has to be gathered from scattered notices in the Hebrew and classical writers, and from a few—a very few—native monuments. The best modern works on the general subject are Movers's *Die Phönizier und das Phönizische Alterthum* (5 vols. 1841–56) and Kenrick's *History and Antiquities of Phœnicia* (1855), to which the writer may perhaps be allowed to add his own *History of Phœnicia* (1889). There is a valuable article by Movers in the *Encyclopædia* of Ersch and Gruber, and another chiefly by Gutschmid in the *Encyclopædia Britannica;* and some excellent essays on the principal characteristics of the Phœnicians, written by Emanuel Deutsch, will be found in his *Literary Remains* (1874). Recently the attention of scholars has been directed mainly to the three points of the geography of the country, the language and literary remains, and the æsthetic art and architecture. The geography has been largely illustrated by Renan in his *Mission de Phénicie* (1864), by Walpole in his *Ansayrii* (1851), by Tristram in his *Land of Israel* (1865), and by Lortet in *La Syrie d'Aujourd'hui* (1884). The language and literary remains, which engaged the attention of Gesenius towards the middle of the 19th century, were subjected by him to careful analysis in his important work, *Scripturæ Linguæque Phœniciæ Monumenta* (1837), which is still an authority of importance; but the work has since been further carried on with remarkable success by Judas, *Études démonstratives de la Langue Phénicienne et de la Langue Libyque* (1842); by the Abbé Bourgade, *Inscriptions Phéniciennes* (1852); by Dietrich, *Zwei Sidonische Inschriften* (1855); by Ewald, *Erklärung der grossen Phönizischen Inschrift von Sidon* (1856); by Schröder, *Die Phönizische Sprache* (1869); and recently by M. Renan and other scholars in the magnificent work entitled *Corpus Inscriptionum Semiticarum* (Paris, 1881–90), where the Phœnician inscriptions occupy almost the entire first volume. Phœnician art and architecture have been largely discussed by M. Renan in his *Mission de Phénicie*, and exhaustively treated by M. Clermont-Ganneau in his work, *L'Imagerie Phénicienne* (Paris, 1880), and by MM. Perrot and Chipiez in their magnificent *Histoire de l'Art dans l'Antiquité* (1882–87), where the subject of Phœnicia occupies the third volume. Byways of Phœnician art have been pursued by General di Cesnola in his *Cyprus* (1877), and by his brother, A. di Cesnola, in his *Salaminia* (1882); also by Ceccaldi, *Monuments antiques de Cypre* (1880); by Signor Cara, *Relazione degli idoli Sardo-fenici* (Cagliari, 1875); and by M. de Vogüé, *Mélanges d'Archéologie Orientale* (1860). Research is still going on upon Phœnician sites, as in the vicinity of Beyrout and Saida (Sidon), and again in Cyprus. The Beyrout journal *Le Bachir* contains from time to time interesting notices of the objects exhumed in Phœnicia proper, while accounts of the work done in Cyprus have appeared in the *Times* and elsewhere.

Phœnix, the name of a mythical Egyptian bird, supposed by some to be a kind of plover, like the *kibitz*, often depicted with human arms, and called in hieroglyphs *rekh*. Others consider it to be the *bennu*, or nycticorax, a bird sacred to Osiris. It visited Egypt after the death of its father, and entered the shrine particularly dedicated to it at Heliopolis, and there buried its parent, putting the body into an egg or case made of myrrh, and then closing up the egg. Another account is that the Phœnix, when about to die, made a nest for itself in Arabia, from which a new Phœnix sprung of itself. This bird proceeded to Heliopolis, and there burned and buried its father. But the more popularly-known version is that the Phœnix burned itself, and a new and young Phœnix sprang from the ashes. The Phœnix was, according to the most authentic accounts, supposed to visit Egypt every 500 years; the precise period, however, was not known at Heliopolis, and was a subject of contention till its appearance. The connection of the Phœnix period with that of the Sothiac cycle appears to be generally received by chronologists, as well as the statement that it designated the soul and the inundation of the Nile. A great difference of opinion has prevailed about the Phœnix period—a cycle generally of 500 years, but varying also from 250 to 7000 years. Lepsius makes it a cycle of 1500 years. The Phœnix was fabled to have four times appeared in Egypt. For

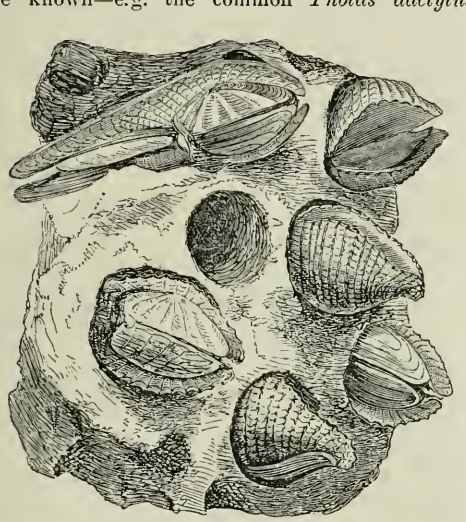
a long and serious argument by a fellow of an Oxford college in 1840 in favour of the existence of the phœnix, see *Notes and Queries* for 22d December 1882, p. 481. He followed Clement, Tertullian, Epiphanius, and other church fathers.

Phœnix. See DATE PALM, and PALMS.

Phœnix Park. See DUBLIN.

Phœnixville, a town of Pennsylvania, on the Schuylkill River, 28 miles by rail NW. of Philadelphia. Here are the extensive works of the Phœnix Iron Company and the Phœnix Bridge Company, which together employ 2400 men. Other manufactures are cotton goods, stockings, shirts, needles, pottery, &c. Pop. (1890) 8514.

Pholas, a genus of marine boring bivalves, of the family Pholadidæ. The shell is thin but hard, gapes at both ends, and has accessory valves. The two principal valves are beset with inequalities, producing a rasp-like structure. Chiefly by means of the foot, but in a manner incompletely understood, these boring molluscs make cylindrical holes in the rocks or in wood. Over thirty living species are known—e.g. the common *Pholas dactylus*,



A piece of rock bored by Pholas.

popularly known as the *piddock*, and the *datolo di mar* of the Italian markets. It is used both for food and bait. The allied genus Pholadidea is also represented on British coasts, and so is the wood-boring Xylophaga. To the family Pholadidæ also belongs the ship-worm, or Teredo (q.v.). See also BORING-ANIMALS.

Phonetics, the science of the sounds of the voice. These are produced by air sent from the lungs through the windpipe, where it may or may not set in vibration two elastic membranes in the larynx, called the 'vocal cords,' producing 'voice' in the first case, and otherwise a wind-rush called 'flatus.' After passing the larynx the voice or flatus enters the mouth (the cavity of which, variously modified by the tongue or lips, affects the sound by its 'resonance'), or else the nose (when the entrance to the same from the throat is not blocked by the pressure of the uvula against the back of the pharynx, greatly modifying the sound by the vibration of the complicated membranes which line the nasal passages), or else both (as in the French nasal vowels). See VOICE, and the illustration of pharynx, uvula, &c. at DIGESTION. Properly speaking, phonetics comprehends the examination of many sounds which are not used in any language, and very different selections have been made by different nations. Here attention is confined to those used in 'received' (as opposed to 'dialectal') English, and a few other European languages.

As the sounds of speech are essentially differentiated by the variously shaped cavities of the mouth, two kinds must be carefully distinguished—'fixed sounds,' where the cavities remain unchanged during utterance; and 'glides,' where the forms of the cavities are constantly changing during utterance. These glides necessarily occur in passing from one fixed position to another, and very often the fixed position is not used for the production of a fixed speech-sound, but merely for the beginning or end of a gliding sound. Thus, in *pat, tak* (italics always indicating systematic writing), the *a* represents a certain fixed sound known as a 'vowel,' but the *p, t, k* represent only fixed positions which have absolutely no accompanying sound, and merely begin or end the (unwritten) glides on to and from the vowel. Hence they were called 'con-sonants' or 'with-sounders,' inasmuch as they sounded with the vowel but not alone. The term 'consonant' has, however, now a much more extended meaning, and the above *p, t, k* are distinguished as 'mutes.' On the other hand, *b, d, g*, in *bad, bag*, have voice-sounds of their own, though very brief and imperfect, and commence and finish the same glides as before, but they are also called consonants, and are distinguished as 'sonants.' Again *s, sh*, in *sash*, have distinct hisses of their own, which can be continued any length of time, but also determine glides on to and from *a*, and are still called consonants, being distinguished as 'hisses.' Similarly *th* and *f*, in *theef*, 'thief,' are hisses and determine glides on to and from *ee*. But in *dhai theev*, 'they thieve,' the *dh, v* are 'buzzes' which can also be continued indefinitely, but have a harsh, grating sound, and when in the pause (but not otherwise) easily lose their voice and end in hisses, as *hiz eizs*, 'his eyes.' The consonants nearest to vowels are the so-called 'liquids'—viz. the two 'flaps,' central *r* and lateral *l*, and the three nasals *m, n, ng* in *roa'ring, lol'ing, sum, sun, sung*. These are so very vowel-like that they can be actually sung upon, especially the three nasals which produce 'hums.'

It would seem to be an easy task to discover at least all the fixed sounds or positions capable of being produced by the organs of speech, and then, noting each by a symbol, leave the glides to form their connection. But it is not so; and had the invention of letters had to depend upon that discovery, we should still have been illiterate. Actually signs were invented for whole words, and then used for the sounds with which they commenced. All was very rough and rude, and the characters chosen could not have been readily altered, even had the requisite knowledge existed. Hence in all languages, and notably in English and French, though the intention of writing was to recall the sound, the word-symbol could not be readily analysed into representatives of the component sounds, till it came to pass for the above two languages that a word seen and not heard could not be uttered, and a word heard and not seen could not be written. Hence arose in many minds the idea of recasting orthography by strict analysis of the sounds—i.e. on a phonetic basis—and to print books in accordance with the new conception, in order to teach reading, at least in the first instance, to children and foreigners. These attempts are popularly spoken of as 'phonetics,' but they are only a practical and very small branch of it, to which it is not necessary to allude further. Some of these alphabets are adapted for the scientific expression of speech-sounds, and among them that here printed in italic letters and called 'Glossic,'

which will now be briefly explained and then considered somewhat in detail. The ordinary spelling is given in roman letters, the Glossic below it in italics.

SHORT KEY TO GLOSSIC.

1. Long stressed vowels—

beat,	bait,	baa,	bought,	boat,	boot.
beet,	*bai·t,*	*baa·,*	*bau·t,*	*boa·t,*	*boo·t.*

With vanishes— *bai·yt,* *boa·wt.*

2. Short stressed vowels—

knit,	net,	gnat,	knot,	nut,	nook.
nit·,	*net·,*	*nat·,*	*not·,*	*nut·,*	*nuok·.*

3. Short unstressed vowels—

merry,	parental,	influence,	follow.
mer·i,	*păren·tăl,*	*in·flooăns,*	*fol·oa.*

4. Vowel diphthongs, unanalysed—

file,	foil,	foul,	fuel.
feil,	*foil,*	*foul,*	*feu·il.*

5. Aspirate—

hay,	behave,	mishap.
hai·,	*bi-hai·v,*	*mis-hap.*

6. Mutes and sonants—

pea	bee,	toe	doe,	cape	gape.
pee·	*bee·,*	*toa·*	*doa·,*	*kai·p*	*gai·p.*

7. Hisses and Buzzes—

whey	way,	feel	veal,	thin	then,
whai·	*wai·,*	*fee·l*	*vee·l,*	*thin·*	*dhen·,*
seal	zeal,	rush	rouge,	hue	you.
see·l	*zee·l,*	*rush·*	*roo·zh,*	*yhoo·*	*yoo·.*

8. Flaps—

ear-ring	hearing,	gull	struggle.
ee·ă-ring·	*hee·ăring,*	*gul·*	*strug·l.*

9. Nasals—

sum	chasm,	pun	open,	sung	hunger.
sum	*kaz·m,*	*pun·*	*oa·pn,*	*sung·*	*hung·gŭ.*

10. Consonantal diphthongs, unanalysed—

chest	fetch,	jest,	judge.
ches·t	*fech·,*	*jes·t,*	*juj·.*

Observe that long vowels under the stress have a turned period (·) after them, and that short vowels under the stress have a turned period after the following consonant. Unstressed short vowels are not particularly indicated here, otherwise than by the stress being marked on some other vowel, except in the case of *ŭ*.

The above scheme suffices for received English, but a few more signs, hereafter assigned, are required for some sounds in received German, Italian, Spanish, and French.

The difference between consonants and vowels is only one of degree. Both have their own special resonance cavities through which flatus, whisper, or voice can pass. But the vowel cavities are best adapted to allow the passage of clear smooth voice, capable of being sung upon with a good quality of tone, and the consonants are more adapted for 'hisses,' or that peculiar mixture of flatus and voice known as 'buzzes.' The 'whisper' proper is a middle kind of sound for which the vocal cords are not brought perfectly close, but close enough to allow the extreme edges of the cords to vibrate as the breath passes, so that a mixture of obstructed flatus and imperfect voice results. Let any one pronounce the above key-words in lines 1 to 4 of the short key in a loud 'stage whisper,' and he will sufficiently seize the effect, which need not be further alluded to, except to draw attention to the difference between whisper and flatus, for the last of which the 'glottis,' or tongue-shaped cavity between the vocal cords, is as widely open as possible, and the sound is produced only by the wind-rush. The reader should try to speak line 1 of the short key with flatus.

The shapes of the resonant cavities of the mouth suitable for vowel-sounds have been analysed by Mr Melville Bell for his 'Visible Speech' into nine kinds according as the back, middle, or tip of the tongue is high, mid, or low, reckoned from the lower jaw to the palate, the mouth in each case being wide open, and the nasal passages closed. Each of these nine can be modified by more or less closing the lips (called 'rounding'), doubling the former number. Again, each of these eighteen vowels may be either narrow or wide. The best phonetists are not yet agreed respecting the cause of this distinction, but its reality is certain, and may be readily perceived by comparing narrow *bee·t* with wide *bit·*, narrow *bai·t* with wide *bet·*, narrow *nau·t* with broad *not·*, narrow *poo·l* with wide *puol·*, 'pull.' By this means thirty-six vowels are obtained, which again can be varied in different ways. English has only twelve different vowels under the stress as shown in lines 1 and 2, and only four need be noticed when unstressed as shown in line 3. But this is a large number. Other languages have generally fewer, and this makes English so difficult for foreigners to pronounce. A few of the foreign vowels, however, present similar difficulties to Englishmen, among which are the following:

ADDITIONAL VOWELS.

ee short, as distinct from *i* in Fr. (French) and It. (Italian).

ae long in Fr. *bae·t*, 'bête;' Ger. (German) *gŭshprae·ky'hŭ*, 'Gespräche.'

aa short in Ger. *maan·*, 'Mann;' It. *aan·noa*, 'anno.'

ah long and short, Fr. *pah*, 'pas,' a broad sound between *aa* and *au*, but not rounded.

ao long and short or middle length, between *oa* and *au*, Fr. *nao·r*, 'nord;' Ger. *kaol·ts*, 'Holz.' Also used by older speakers in English as *mao·ă;* now usually *mau·ă*, 'more.'

eo narrow in Fr. *peo·*, 'peu;' Ger. *Geo·tŭ*, 'Goethe,' a narrow *ai* without vanish, spoken with the lips rounded as for *oa.*

oe wide, Fr. *voe·v*, 'veuve;' Gr. *Boek·ŭ*, 'Böcke,' a wide *e*, spoken with the lips rounded as for *oa.*

ue long and short, Fr. *aafue·*, 'affût,' *uet·*, 'hutte;' Ger. *ue·bŭr*, 'über,' *uep·iky'h*, 'üppig,' a broad *i* (or, as Dr Sweet thinks, a narrow *ee*), with lips rounded as for *oo.*

THE FOUR FRENCH NASALS.

aen' in *vaen'*, 'vin,' an attempt to say *ae* or *a* with the nasal passages fully open.

aan' or *ahn'* in *saan'* or *sahn'*, 'sans,' an attempt to say *aa* or *ah* with the nasal passages fully open.

oan' or *aon'* in *boan'* or *baon'*, 'bon,' an attempt to say *oan* or *aon* with the nasal passages fully open.

oen' or *un'* in *oakoen'*, 'aucun,' an attempt to say *oen* or *un* with the nasal passages fully open.

When two different vowels glide into each other they form a diphthong. Line 4 of the short key shows the four principal diphthongs purposely noted by arbitrary instead of systematic signs. If we wished to represent their analysis we should write *fuyl*, *foyl*, *fuwl*, *fyoo·il*, where the *y* and *w* are used to show very short unstressed *i*, and *uo*, which form the second element of the first three, the first element being short but stressed. In the cases of 'way,' 'know,' and similar words, especially in the pause, it is very usual in the south of England to let the voice glide off to a *y* and *w* sound known as the 'vanish;' but then the first element is long, as *wai·y*, *noa·w*. There are, however, a number of 'murmur diphthongs' where the second element is the murmur *ŭ*, into which the flap *r* degenerates (in London, not in Scotland), as shown for *ŭ*

in line 8 of the short key, or in the four usual cases—*ee·ŭ* or *i·ŭ*, 'ear;' *e·ŭ* 'air;' *uo·ŭ* or *au·ŭ*, 'oar;' *poo·ŭ* or *puo·ŭ*, 'poor.' The *r*, however, revives if a vowel follows, as *hee·ŭ, hee·ŭring*, 'hear, hearing;' *pao·ŭ, pao·ŭring*, 'pour, pouring;' or *pau·ŭ, pau·ring*, more commonly in London.

The mode in which a vowel begins to sound is called a 'glottid,' because it depends upon the opening of the glottis. If the vocal cords are quite close and ready to act, as they should always be in singing, the vowel-sound commences immediately on the breath reaching the larynx, and this is called the 'clear' glottid. If the closure of the glottis be exaggerated, so that the vowel comes out with a kind of explosion, the result is the 'catch' glottid, written (;) in discussions. This is common before all vowels beginning words or compound parts of words in German, as *;aay·nŭ, ;er;in·ŭruong*, 'eine Erinnerung.'

On the other hand, if the glottis is not quite closed at first, but closes gradually as the breath passes, we have first a slight escape of flatus, followed by a slight whisper, and then by the vowel itself. This forms the 'gradual' glottid, which is not uncommon, especially in passing from a hiss to a vowel, as in *see;* and even from a mute to a vowel, to distinguish more clearly mutes from sonants, as *pee* from *bee*. As a general rule none of these three glottids need be marked, though the 'gradual' may be distinguished in phonetic discussions by (°), as *pee, p°ee*. A similar effect called the 'recoil' occurs after mutes in the pause, and may be written in the same way in discussions; compare *pop°·* with *pop·gun*, not *pop°·gun*. An exaggeration of this (°) often occurs in the so-called 'aspirate' or 'rough breathing,' which essentially consists of a jerked emission of breath, whether voice or flatus, and the exertion of jerking out a vowel often introduces a strong flatus through the vowel position. Both are represented by *h* (or, when not initial, to prevent confusion, by *-h*), but in discussions the latter may be represented by *h°*, as *hot, h°ot*.

The consonants which have positions that gradually diminish in the power of allowing distinct voice to pass from the nasal liquids, as *m*, through the lateral liquid *l*, the flap *r*, the buzzes, as *z*, and hisses, as *s*, to the sonants, as *d*, and the mutes, as *p*, may be arranged either as in the short key or by the parts of the vocal organs which form the passage (putting, however, the mutes first as most marked by absolute stoppage of voice) as in the table, where capitals refer to the short key, and the other letters are explained afterwards.

TABLE OF CONSONANTS.

	Contacts or Straits formed by	Lips.			Tongue Tip.				Tongue Mid.			Tongue Back.

ix.	Flated						*nh*						
x.	Voiced	*M*				*n'*	*N*		*ny'*			*NG*	

ADDITIONAL CONSONANTS.

Col. 2. *f', v'* are *f, v* without touching the teeth, and of these *v'* is the regular German 'w.' Both occur in modern Greek and Hungarian.

Col. 5. *t' d', l', n'* are the common continental forms of our *t d, l, n*, the tip of the tongue being brought more forward, so as to lie fully against the gums. The first two occur dialectally sometimes before r, but are not received. They need not be distinguished from *t d, l, n*, except in discussions.

Col. 6. *sh' zh'* are *sh zh* pronounced without the hollow at the back of the tongue, which is more in the *ee*-position. But the distinction need not be made except in discussions.

lh, nh are the flated voiceless forms of *l, n*. The first occurs unilaterally in the Welsh 'll,' and the latter dialectally in English for initial 'kn' in 'know.'

Col. 8. *ly', ny'* are attempts to pronounce *l* and *n* at the same time as *y*, and hence are different from *ly, ny* in *milyŭn, minyŭn*, 'million, minion,' where the *y* follows. They occur as 'gl, gn' in Italian 'figlio, segno,' *fee·ly'oa, sai·ny'oa*, and Spanish 'll, ñ.' The *ly'*, although still written as 'ill' in French, has of late been replaced in speech by simple *y*, but *ny'* remains as 'gn;' thus, 'sillon, signer,' *siyoan', siny'ai*.

Col. 10. *ky', gy'* are attempts to utter *k, g* at the same time as *y*, and used to be heard (may still occasionally be heard), as in 'cart guard,' *ky'aa·t gy'aa·d*, and similar words.

ky'h, gy'h are the hissed and buzzed forms of *ky', gy'* in German *zee·ky'h zee·gy'hŭ*, 'siech siege;' but *ky'h gy'h* are considered by some (even German) phonetists as the same as *yh, y;* thus, *zee·yh, zee·yŭ*.

Col. 11. *kh, gh* are the hissed and buzzed forms of *k, g*, in German *zaakh'ŭ zaa'ghŭ*, 'sache sage,' and kh occurs also in Scotland. It is the Spanish 'j,' sometimes 'x' or 'g,' before 'e, i,' as *ee'kho, keekhaa·te, khee·fe*, 'hijo, Quixote, gefe (jefe).'

'*rh*, '*r* are flaps made with the uvula instead of the tip of the tongue; '*r* is common in Northumberland, in north France, and in north Germany, where also '*rh* is found in the pause, as in '*riky'h·t'ŭ'rh*, 'richter.'

Col. 12. *kw', gw'* arise from an attempt to utter *w* at the same time as *k, g*, and *kw'h, gw'h* are the corresponding hiss and buzz in German *t'aawkw'h·ŭn', t'aawgw'h·ŭn'*, 'tauchen, taugen.'

This table is of course very incomplete, but it will serve as a framework for introducing other consonantal sounds. The glides of all these consonants to and from all the vowels should be carefully studied in actual words, but cannot be considered here.

Speech consists of sentences, and it is only by careful analysis that these are separated into words, syllables, glides, and fixed sounds, so that the letters which represent the last only, and have here been treated first, are determined with much difficulty among the mass of sound heard. Any one who attempts to write an unknown language from pure dictation, without seeing its usual writing (if it have one), will feel this immediately. And from this mass of sound to disentangle the words, as they are usually separated, is still more difficult.

An attempt has been made by Dr Sweet for English (*Elementarbuch des gesprochenen Englisch*, Leip. 1886, and *Primer of Spoken English*, Oxford, 1890), and by M. Paul Passy for French (*Les Sons du Français* and *Le Français parlé*, both 1889), to write exactly what is spoken, dividing the words, or sometimes only dividing the breath-groups, and a study of these books will show the difficulty of the problem. *The Existing Phonology of English Dialects* (1889), by the late Dr Ellis, the writer of this article, shows an attempt to write all English dialects, practically previously unwritten, and mostly from pure dictation, and very difficult it was found, the alphabet here given being quite insufficient for the purpose. For a fuller account of phonetics, reference may be made to his *Speech in Song* (1878), in which this alphabet is used. See also the articles in this work on Alphabet, Grimm's Law, Letters, Shorthand, Visible Speech, Voice.

To show the nature of phonetic writing, this rapid sketch of the subject may be concluded with a rough attempt to write received English in the educated colloquial form used in London (not in Scotland).

Example of Phonetic Spelling.

Ah! father, I am sure, that that new branch of our George's favourite woodbine, which is growing near the post not far from the north wall of the garden, must be safe to measure about two feet, or more, in length to-day, unless some mishap is occurring or it has suddenly lost its usual vital energy; for I have carefully observed its rate of increase every week this month, and noted it down accurately on your slate, and I know it has experienced no variation, barring once, during a desperately annoying interval of cold, pouring rain.

Phonograph, an instrument for mechanically recording and reproducing articulate human speech, song, &c. The phonograph was invented by Mr T. A. Edison (q.v.) in the spring of 1877, at his Menlo Park Laboratory, New Jersey, and came into existence as the result of one of the many lines of experiment he was then engaged upon. Following up some of his telegraphic inventions, he had developed a machine, which by reason of the indentations made on paper, would transfer a message in Morse characters from one circuit to another automatically, through the agency of a tracing-point connected with a circuit-closing device. Upon revolving with rapidity the cylinder that carried the indented or embossed paper Mr Edison found that the indentations could be reproduced with immense rapidity through the vibration of the tracing-point. He at once saw that he could vibrate a diaphragm by the sound-waves of the voice, and, by means of a stylus attached to the diaphgram, make them record themselves upon an impressible substance placed on the revolving cylinder. The record being made thus, the diaphragm would, when the stylus again traversed the cylinder, be thrown into the same vibrations as before, and the actual reproduction of human speech, or any other sound, would be the result. The invention thought out in this manner was at once tried, with paraffined paper as the receiving material, and afterwards with tinfoil, the experiment proving a remarkable success, despite the crudity of the apparatus. In 1878 Mr Edison made a number of phonographs, which were exhibited in America and Europe, and attracted universal attention. The records were made in these on soft tinfoil sheets fastened around metal cylinders. For a while Mr Edison was compelled to suspend work on this invention, but soon returned to it and worked out the machine as it exists practically to-day. It occupies about the same space as a hand sewing-machine. A light tube of wax to slide on and off the cylinder is substituted for the tinfoil, which had been wrapped around, and the indenting stylus is replaced by a minute engraving point. Under the varying pressure of the sound-waves, this point or knife cuts into the tube almost imperceptibly, the wax chiselled away wreathing off in very fine spirals before the edge of the little blade, as the cylinder travels under it. Each cylinder will receive about a thousand words. In the improved machine Mr Edison at first employed two diaphragms in 'spectacle' form, one to receive and the other to reproduce; but he has since combined these in a single efficient attachment. The wax cylinders can be used several hundred times, the machine being fitted with a small paring tool which will shave off the record previously made, leaving a smooth new surface. The machine has also been supplemented by the inventor with an ingenious little electric motor with delicate governing mechanism, so that the phonograph can be operated at any chosen rate of speed, uniformly. This motor derives its energising current either from an Edison-Lalande primary battery, a storage battery, or an electric-light circuit.

Copyright 1891 in U.S. by J. B. Lippincott Company.

The new and perfected Edison phonograph has already gone into very general use, and hundreds of thousands are distributed in American business offices, where they facilitate correspondence in a variety of ways. They are also employed by stenographers as a help in the transcription of their shorthand notes. Heretofore these notes have been slowly dictated to amanuenses, but they are now frequently read off to a phonograph, and then written out at leisure. The phonograph is, however, being used for direct stenograph work, and it reported verbatim 40,000 words of discussion at one convention held in 1890, the words being quietly repeated into the machine by the reporter as quickly as they were uttered by the various speakers. A large number of machines are in use by actors, clergymen, musicians, reciters, and others, to improve their elocution and singing. Automatic phonographs are also to be found in many places of public resort, equipped with musical or elocutionary cylinders, which can be heard upon the insertion of a small coin; and miniature phonographs have been applied to dolls and toys. The value of the phonograph in the preservation of dying languages has been perceived too, and records have already been secured of the speech, songs, war-cries, and folklore of American tribes now becoming extinct. It is also worthy of note that several voice records remain of distinguished men, who 'being dead yet speak.' Their tones can now be renewed at will, and their very utterances, faithful in accent and individuality, can be heard again and again through all time.

Improvements are being made in the wholesale reproduction of phonographic cylinders, by electrotyping and other processes; and the machine, in a more or less modified form, is being introduced as a

means of furnishing a record of communications through the telephone. Phonographic clocks, books, and other devices have also been invented by Mr Edison, whose discovery is evidently of a generic nature, opening up a large and entirely new field in the arts and sciences. See also TELEPHONE.

Phonography. See SHORTHAND.

Phonolite. See CLINKSTONE.

Phormium. See FLAX (NEW ZEALAND).

Phosphates. See PHOSPHORUS, MANURE.

Phosphatic Diathesis, in Medicine, designates the condition in which there is a tendency in the Urine (q.v.) to deposit white gravel.

Phosphorescence. Strictly speaking, the term is applied to the phenomenon, exhibited by certain bodies, of remaining luminous in the dark for some time after being exposed to a strong light. Certain preparations, such as calcium sulphide (see LUMINOUS PAINT), indurated limestone, &c., possess this property in a very high degree. With the great majority of phosphorescent bodies, however, the duration of the phenomenon is very short, rarely more than a small fraction of a second. Becquerel, who studied this phenomenon with great care, invented a very ingenious instrument for the purpose, called a *phosphoroscope*. The body to be tested is placed in a small drum, which has an opening at each end. In this drum there revolve two discs, mounted on the same axle, and pierced symmetrically with the same number of holes. They are so adjusted that when a hole in one disc is opposite to the hole in the corresponding end of the drum the second disc closes the hole at its end of the drum, and *vice versâ*. Light is admitted by one of the holes in the drum so as to fall on the object, and it is examined through the other hole. It is obvious that, when the discs are made to revolve, the object is alternately exposed to light and presented to the eye. By a train of multiplying wheels, these alternations may be made to succeed each other as rapidly as the observer pleases, and thus the object is presented in the dark to his eye as soon after its exposure to light as may be desired. Almost all bodies are found to be phosphorescent; for instance, some kinds of pink rubies when exposed to sunshine in this apparatus appear to glow like live coals in the dark. When phosphorescence is continuous, bodies receiving light and giving off radiation of a lower refrangibility, we have the phenomenon observed by Brewster and Herschel in quinine and certain crystals of fluor-spar, and thence called *Fluorescence*. The green colouring matter of leaves, a decoction of the bark of the horse-chestnut, and the common *canary* glass (coloured with oxide of uranium) are bodies which exhibit this phenomenon very well. Perhaps the most striking method of studying the phenomenon is to receive in a darkened room the solar Spectrum (q.v.) on a sheet of white paper, and to pass over the coloured spaces a brush dipped in a solution of sulphate of quinine with sulphuric acid. No change is produced on the less refrangible rays, but in the blue and indigo spaces a strange change of colour is at once apparent where the liquid has been spread. This appears more strongly in the violet, and vividly in the spaces beyond the violet, where rays fall which excite no luminous sensation in the eye. By this experiment the visible length of the spectrum may easily be doubled. By using the electric light, which is peculiarly rich in these highly-refrangible rays, a prism of quartz, which allows them to pass very freely, and various fluorescent substances, Stokes has obtained spectra six or eight times as long as those otherwise visible. The characteristic of all these rays is that they are *less* refrangible than those from which they are produced. The entire phenomenon is, as Stokes first showed, identical in principle with Leslie's photometer, in which light was measured when changed into heat by absorption in the coloured glass, of which one of the bulbs of his differential thermometer was formed. Ordinary phosphorus (from which the phenomenon took its name) becomes luminous in the dark by slight friction; whence the common trick of drawing self-luminous figures on doors and walls with a stick of phosphorus, or an ordinary lucifer match wetted.

PHOSPHORESCENCE IN ORGANIC BEINGS.—The emission of light by minerals after insulation and the cognate phenomena of luminosity on heating, friction, cleavage, crystallisation, &c. are of quite different nature from the production of light by organisms, the special subject to which we now turn.

Luminosity due to Putrefaction or to Disease.—The fact that many organic substances (especially fish) become luminous when decaying has long been known, and has often been erroneously adduced as the chief cause of the phosphorescence of the sea. It is only quite recently that the discovery of luminous bacilli has rendered possible any general explanation of these facts, and even yet its wide applicability remains to be proved. They have been shown to exist in several instances which will be mentioned below, and the constant association of these low forms of life with putrefactive processes at once suggests the hypothesis that luminosity under such circumstances may be due to their presence. Perhaps they may also account for the few instances in which the human body has been recorded as phosphorescent during life.

Luminosity of Healthy Living Organisms.—(1) In the *vegetable* kingdom the instances of the occurrence of this property are but few, and the majority of these belong to the algæ and fungi, the bacilli or bacteria above mentioned being referable to the former. Most of the fungi are Hymenomycetes (*Agaricus*, spp.): in some cases the mycelium (root-like threads) gives out the light; in others, as in *A. olearius*, not uncommon at the roots of olive-trees, it is the under surface of the mushroom-like head. The light is only seen while growth is progressing; it ceases so soon as the fungus is mature. A moss (*Schistostega osmundacea*), some grasses, a Euphorbia (*E. phosphorea*), a lily (*Lilium bulbiferum*), a poppy (*Papaver orientale*), and a nasturtium (*Tropæolum majus*) have all been recorded as luminous. The last instance is worthy of note as having been observed by the daughter of Linnæus in 1762.

(2) In the *animal* world there is not one of the larger groups, up to and including the fishes, which does not afford some good examples of this phenomenon. A complete list of these would be outside the scope of such an article as the present; it must suffice to mention some of the best instances in each class, indicating briefly the nature of the photogenic mechanism. Among the Protozoa the small spheroidal *Noctiluca miliaris* is perhaps the most widely spread instance of this property, this organism, or others allied to it, abounding at certain times around the coasts of the greater part of the world. The light is emitted from the general protoplasm of the body; a pocket-lens shows some points to be brighter than others, whilst a higher magnifying power shows these to be really groups of smaller points, just as a nebula is gradually resolved into stars by increasing powers of the telescope. On the high seas Noctiluca seems to be replaced by species of Pyrocystis, one of the discoveries of the *Challenger* expedition; these may possibly, however, be stages in the life-history of very similar forms. Among the Porifera (sponges) the only recorded luminous form is the larva of a species of Reniera. The poverty of this class is,

however, more than compensated by the wealth of the Cœlenterata. The common hydroid colony *Obelia geniculata*, often growing upon the fronds of Laminaria (sea-tangle), is a familiar instance. Numerous Medusæ (jelly-fishes) must be added to the list; and here the light is variously emitted in different species: (*a*) from the whole surface; (*b*) from the marginal corpuscles; (*c*) from the radial canals; (*d*) from the ovaries. Sometimes the same genus includes both luminous and non-luminous forms. Most Pennatulidæ (sea-pens) furnish instances of the possession of this property; such are the long, reed-like Funiculina found in Loch Torridon (Ross-shire) and on other parts of the Scottish coast, and Pennatula, the subject of classic researches by Panceri, where the light emanates from eight bands or tracts of specially modified tissue situated in the wall of the stomach. Alcyonarians, Siphonophores, and Ctenophores also furnish contributions to the list; amongst these last the small ovoid jelly Beroë was shown by Allman not to give out its light until it had remained for some time in the dark.

A few species of Ophiuroids (brittle stars) and the deep-sea asteroid Odinia constitute the only known instances of luminosity among the Echinodermata, but the worms furnish a larger array. More than one case has been noticed among earthworms, the most complete description being due to Professor Giard. This worm (Photodrilus) is 1½ to 2 inches long, and the luminous material is due to a series of glands opening into the œsophagus. In these forms the luminosity ceases immediately after sexual congress. Among the marine Chætopoda the power resides in the dorsal scales (elytra) of the Polynoidæ, the tentacles, dorsal tubercles, &c. of Chætopterus, and the bunch of cephalic tentacles of Polycirrus.

Of phosphorescent mollusca the small pelagic *Phylliroë bucephala* is of importance, because the transparency of its tissues permits of its easy study and the successful localisation of its luminosity, which is found to reside in nerve ganglia, as well as in certain small rounded cells situated at the ends of the nerve twigs. The rock-boring bivalve (Pholas) is one of the longest known instances of animal phosphorescence, being recorded by Pliny, who noticed that if any one chews the animal the whole interior of his mouth becomes luminous. In this form the light is emitted from five definite patches all situated within the mantle cavity—(1) an arc corresponding with the anterior margin of the mantle, (2, 3) two triangular patches near the opening of the branchial siphon, (4, 5) two long parallel bands within the same siphon. The luminous material is secreted by the epithelial cells covering these portions of the body, and has been shown to consist essentially of two substances, a white crystalline body (luciferine) and a ferment (luciferase); by the mixture of these two in a test-tube it is possible to reproduce the light at will, without the presence of living matter. The ferment is most likely produced by a certain bacillus, which occurs in large numbers in small pits in the walls of the siphon.

Interesting observations upon bacilli as the cause of phosphorescence have also been made on Crustacea of the genera Talitrus and Orchestia (sand-hoppers) in a state of disease; the malady, and the consequent luminosity, can be transferred to healthy specimens by inoculation, and the germs can be reared in artificial media in the usual manner. It would appear that the sand-hoppers infect themselves with the bacilli from dead fish on which they habitually feed. Many other Crustacea, however, are luminous under normal conditions, as, for instance, some Copepoda (Sapphirina), and more particularly the Schizopoda, one of which, *Nyctiphanes norvegica*, is not uncommon in the deep waters of Loch Fyne as well as on the Norwegian coast. Definite organs (photosphæria) are here present for the production of light; one in the stalk of each eye, one at the root of each first, and one at the root of each penultimate, thoracic limb, and one under each of the first four segments of the abdomen. Each organ, as has been proved by microscopic sections, is in reality a miniature bull's-eye lantern, only equalled in complexity by the organs of certain fishes. Several phosphorescent Ascidians are known, the most conspicuous being the pelagic colony Pyrosoma, in which each individual zooid has two rounded luminous organs. The researches of the recent deep-sea expeditions have revealed quite a large number of phosphorescent fishes, with specialised organs of many different types. Some of these appear to be glandular, whilst others are optical instruments of great complexity, with spheroidal and parabolic reflectors to send the light in definite directions and with lenses to concentrate it. In some of the abyssal Lophioids (angler-fish) the modified dorsal fin-ray which acts as a lure has a phosphorescent extremity, no doubt to render it more attractive.

There still remain for consideration the phosphorescent *insects*, which belong almost exclusively to the Hemiptera (bugs) or the Coleoptera (beetles). To the former belong the lantern-flies (Fulgora and allied genera), though it must be mentioned that the possession of this power by these insects has been denied by more than one good observer. Luminous beetles appertain to the families Lampyridæ and Elateridæ. The glow-worm (*Lampyris spendidula*) and the Italian firefly (*Luciola italica*) are good examples of the former, and have been often described. In both cases the organs, which are situated in a certain number of the posterior segments of the abdomen, consist of two layers, of which the dorsal contains large quantities of uric acid salts, and the ventral clear cells, which are arranged in cylindrical lobules. In some species both sexes are luminous, in others only one. In the Mexican firefly or Cucúyos (*Pyrophorus noctiluca*), which belongs to the Elateridæ or click-beetles, the organs are three in number, one in each upper and hinder angle of the prothorax, and one much larger occupying the centre of the ventral surface of the first abdominal segment. This last is invisible while the insect is at rest, but shines forth when it spreads its wings and raises its abdomen in flight. Both the eggs and larvæ of this species are luminous.

As regards the physical peculiarities of the light, it varies in colour in different cases, being blue in the mycelium growing in rotten wood, in Cunina, Beroë, Pyrosoma, and Lampyris; green in a species of Agaric, Pteroeides, in Ophiuroids, and in Pyrophorus; yellow in Noctiluca, Bolina, and with a reddish tinge in a species of Cestum; purple in Funiculina and Fulgora; whilst in *Pyrosoma atlanticum* and an Appendicularia observed by Giglioli it has been stated that the light varies in colour. In all cases in which the matter has been investigated the spectrum has been found to be continuous; the amount of heat given off in connection with the process seems to be quite infinitesimal, though actinic rays have been shown to be present. The phenomenon would appear to consist in a definite vital process, which, in these cases, leads to the production of radiant energy just as in other instances to the evolution of heat or of electricity.

The uses of this property to its possessors may, so far as is known at present, be grouped under four heads: (*a*) It enables the sexes to find each other, as in Luciola and earthworms; (*b*) it is possessed by so many stinging Cœlenterates that

in them we may fairly regard it as a warning signal, and it may have been adopted by stingless forms for the same purpose by mimicry; (*c*) it may serve to attract prey, as in the phosphorescent lure of the deep-sea angler-fish (Melanocetus, &c.); (*d*) it may illuminate the surrounding regions and enable the light-producing animal to find its way, as in *Pyrophorus*, *Nyctiphanes*, and many deep-sea fish. So many deep-sea animals are possessed of luminous qualities that it has been assumed that these living lights play an important part in the economy of life in those regions; this hypothesis is commonly known as the 'abyssal theory of light.' See the articles FIREFLY, GLOW-WORM, and works there cited.

Phosphorus (sym. P; atom. wt. 31; molec. wt., vapour = P_4 = 124; do. at white heat, P_2 = 62) is one of the metalloids or non-metallic elements, although, in its combining relations, it is closely connected with the metals arsenic and antimony. This substance affords an excellent example of Allotropy (q.v.); that is to say, it may be made to occur under different forms presenting different properties. Ordinary phosphorus and the red variety are the only important forms. We shall speak of them as phosphorus and red phosphorus respectively.

Phosphorus at ordinary temperatures is an almost colourless or faintly yellow solid substance of sp. gr. 1·836, having the glistening appearance and the consistence of wax, and evolving a disagreeable alliaceous odour, which, however, is probably due to the action of the oxygen of the air upon it. It fuses at 44·2° C. (111·5° F.) into a colourless fluid; and, if the air be excluded, it boils at 290° C. (554° F.), and is converted into a colourless vapour of sp. gr. 4·35 (air = 1·00). If, however, it be heated to about 60° C. (140° F.) in the air it catches fire, burns with a brilliant white flame, and is converted into phosphoric anhydride; and indeed it is so inflammable that it will catch fire at ordinary temperatures by mere friction. As the burns which it occasions are often severe and dangerous, great caution is required in handling it; and in consequence of the readiness with which it catches fire, and of its tendency to oxidise when exposed to the air at a temperature higher than 0° C. (32° F.), it is always kept in water, in which it is insoluble. It is slightly soluble in ether, but dissolves freely in benzol, in the fixed and essential oils, and in bisulphide of carbon; and, on allowing its solution in a volatile solvent to fall upon filtering paper, the finely-divided phosphorus absorbs oxygen so rapidly as spontaneously to catch fire as soon as the solvent has evaporated. Phosphorus shines in the dark from the slow combustion which it undergoes; and hence its name, from the Greek words *phōs*, 'light,' and *phoros*, 'bearing.' Its power of forming ozone is noticed in the article on that substance. Taken internally, phosphorus is a very powerful irritant poison; and it is the active ingredient of some of the preparations employed for the destruction of vermin. Its fumes give rise to a peculiar form of necrosis of the jaw and to fatty degeneration of the kidney, which used to be common amongst the makers of lucifer matches.

Red phosphorus is prepared from the ordinary variety by heating the latter in a closed iron vessel to a temperature of 240° C. (464° F.). It was discovered by Schrötter in 1845, and is a compact solid substance of a dark red colour, and with a metallic lustre. It differs much in its properties from common phosphorus, being devoid of odour, does not shine in the dark, undergoes no change when exposed to the air even for years, and cannot be set on fire by moderate friction or percussion. Moreover, it is insoluble in all the solvents of common phosphorus, and is not poisonous. It bears heating to nearly 260° C. (500° F.) without taking fire, and has a specific gravity of 2·16. By using red instead of white phosphorus for lucifer matches there is no risk to the health of the operatives. Safety matches contain chlorate of potash and ignite on a surface containing a mixture of red phosphorus and sulphide of antimony (see MATCHES).

Phosphorus is not met with in nature in an uncombined state; but it occurs in rocks of various kinds and ages, and in some countries abundantly as apatite or phosphorite, both of which are composed of phosphate of lime. It is also found in the form of Coprolites (q.v.), or the dung of extinct animals, and more rarely as wavellite (phosphate of alumina) and vivianite (phosphate of iron). In many volcanic rocks apatite is found in minute crystals or particles, and by the decomposition of these rocks it passes into the soil. From the soil it is extracted by plants, which accumulate it (especially in the seeds of the cereals) in quantity sufficient for the wants of the animals which they supply with food. In the animal system phosphate of lime forms 57 per cent. of the bones; phosphates of the alkalies, especially of soda, occur freely in the animal fluids; and in fibrine, albumen, and nervous matter phosphorus is universally present, although we do not clearly know in what form of combination it occurs.

Phosphorus was originally discovered in 1669 by Brandt, a Hamburg chemist, who obtained it from urine. Gahn and Scheele were, however, the first to discover its presence in bone, and to employ that material for its preparation. The following are the leading steps of the method now usually employed in obtaining it on the large scale. Bones are burned to whiteness, and powdered; and this bone-ash is then mixed with sulphuric acid in such quantity as to decompose the phosphate of lime occurring in the ash, $Ca_3(PO_4)_2$, partly into insoluble sulphate of lime, partly into a soluble superphosphate of lime, whose composition is represented by the formula $H_4Ca(PO_4)_2$. The solution of the superphosphate is evaporated to a syrup, mixed with charcoal, and submitted to distillation in an earthen retort exposed to a red heat. Phosphorus rises in vapour, and is conveyed by means of a bent tube into water, in which it condenses in yellow drops. Two distinct processes take place within the retort. The first consists in the decomposition of the superphosphate of lime into bone-earth and hydrated phosphoric acid; while the second consists in the deoxidation, by means of the carbon, of the liberated phosphoric acid into phosphorus—a process accompanied by the evolution of carbonic oxide gas. After being pressed in a fused state through wash-leather, and further purified, it is forced into tubes, in which it is allowed to solidify, giving it the usual form of *sticks*. Sombrerite (see APATITE) is now largely substituted for bones in the manufacture of phosphorus.

Phosphorus forms two known oxides—phosphorous anhydride, P_2O_3, obtained by the slow oxidation of phosphorus in dry air; phosphoric anhydride, P_2O_5, obtained by the combustion of phosphorus in an excess of dry air or oxygen. The latter is a snow-like substance which has a great avidity for water, and is therefore very useful in the laboratory as a desiccating agent.

Phosphorus forms five acids—hypophosphorous acid, $H{\cdot}PH_2O_2$, monobasic (the anhydride, P_2O, is not known); phosphorous acid, $H_2{\cdot}PHO_3$ ($= P_2O_3 + 3H_2O$), dibasic, obtained by slow oxidation of phosphorus in moist air or by passing chlorine gas through phosphorus under hot water; metaphosphoric acid, HPO_3 ($= P_2O_5 + H_2O$), monobasic, obtained by dissolving P_2O_5 in water or by heating ordinary phosphoric acid to redness; pyrophos-

phoric acid, $H_4P_2O_7$ ($= P_2O_5 + 2H_2O$), tetrabasic, obtained by acting upon lead pyrophosphate with sulphuretted hydrogen, the lead salt being prepared from soda pyrophosphate, which is obtained by heating such a phosphate as Na_2HPO_4, of which two molecules give off one of water and form $Na_4P_2O_7$; phosphoric or orthophosphoric acid, H_3PO_4, tribasic, prepared by boiling P_2O_5 in water, or from bone-ash and sulphuric acid; the last-named acid has three sets of salts, the hydrogen in the acid being more or less completely replaced —e.g. NaH_2PO_4, Na_2HPO_4, and Na_3PO_4, which are obtained by more or less completely neutralising phosphoric acid with soda.

The discovery of phosphoric acid was made in 1740 by Marggraf; the discovery of its true chemical nature is, however, due to Lavoisier, and that of its various modifications and its polybasicity to the investigations of Graham. The salts of phosphoric acid are phosphates; and they are of great value, when in a soluble form or when they can become soluble through weathering, as manures (see MANURE). Of late years mineral phosphates have been largely worked up; and a new source of phosphatic manure has become available in the alkaline slag of the Thomas-Gilchrist process, whereby the phosphorus is removed from iron by means of lime.

Phosphorus combines with hydrogen in three proportions to form phosphuretted hydrogen gas, PH_3; liquid phosphide of hydrogen, P_2H_4; and solid phosphide of hydrogen, P_4H_2. Of these the first alone requires notice in these pages. There are various processes for obtaining the gas, one of the simplest being by boiling fragments of phosphorus in a concentrated solution of hydrated potash, in which case hypophosphite of potash is formed, while phosphuretted hydrogen gas is extricated. The reaction is explained by the equation $4P + 3KHO + 3H_2O = 3KPO_2H_2 + PH_3$. The gas thus evolved is colourless, possesses a characteristic fœtid odour, and has the remarkable property of taking fire spontaneously in atmospheric air or in oxygen gas, with the production of anhydrous metaphosphoric acid and water. There is reason to believe that *perfectly pure* phosphuretted hydrogen gas does not possess the power of igniting spontaneously, and that the self-lighting gas always contains a minute quantity of the vapour of the liquid phosphide, P_2H_4. The luminous phenomenon known as Ignis Fatuus (q.v.) has been referred to the natural evolution of the gas. The compounds of phosphorus with sulphur, chlorine, iodine, bromine, &c. are not of practical importance.

Phosphorus is rarely employed in medicine as a nervous stimulant, in consequence of its poisonous properties. The symptoms induced by this poison are those of acute inflammation of the stomach and bowels; the treatment is the administration of large quantities of mild demulcent fluids, and of magnesia. Dilute phosphoric acid is included in the British Pharmacopœia, but is not very much employed. It may be prescribed in much the same cases as those in which sulphuric and nitric acids are employed, and is less likely to disturb the digestive functions, if employed for a long period, than the other mineral acids. It has also been recommended, when properly diluted, as a serviceable acidulated drink for assuaging the thirst in diabetes. It may be prescribed in half-drachm doses. For medicinal phosphates, see SYRUP.

Photius, Patriarch of Constantinople at a critical period, was a member of a patrician family of Constantinople, and was born in the early part of the 9th century. Distinguished by his abilities, he served in various important public offices, and secured the favour of the Emperor Michael and his powerful favourite Bardas. The patriarch Ignatius, having in vain tried to correct the vices of the profligate emperor, was deposed and banished. Photius, although a layman, was appointed in his stead, hurried in a few successive days through all the stages of sacred orders, and finally installed as patriarch. Two successive councils of bishops under court influence confirmed the deposition of Ignatius and the election of Photius. In 862, however, Pope Nicholas I. (q.v.) called a new council at Rome, which declared Photius' election uncanonical and invalid, deposed and excommunicated him, and reinstated Ignatius in his see. Being supported, however, by the emperor, Photius retained possession, and retaliated on the pope by assembling a council at Constantinople in 867, in which he raised a controversy of doctrine and discipline between the churches of the East and West themselves. In all these doctrinal differences the council condemned the Western Church, excommunicated Nicholas and his abettors, and withdrew from the communion of the see of Rome. Michael being put to death by Basilius the Macedonian in 867, Photius was banished to Cyprus, and Ignatius reinstated; and in 869 the eighth general council, at which Pope Adrian II.'s legates presided, was assembled at Constantinople. Photius was again condemned and excommunicated, and the intercommunion of the churches restored. Yet on the death of Ignatius Photius was reappointed to the patriarchate. In 879 he assembled a new council at Constantinople, renewed the charge against the Western Church, and erased from the creed in the article on the Procession of the Holy Ghost the word *filioque* (see SPIRIT). The separation of the churches, however, was not completed till the time of Michael Cerularius (see GREEK CHURCH). Photius was finally deprived, and exiled to Armenia by Leo, the son of Basilius, in 886, and died soon afterwards, probably in 891. His chief remains are *Myriobiblon*, called also *Bibliotheca*, a summary review of 279 works which Photius had read, many of which are now lost; a *Lexicon;* the *Nomocanon*, which is a collection of the acts and decrees of the councils and ecclesiastical laws of the emperors; several minor theological treatises; and a collection of letters, many of them extremely interesting and elegant. See Hergenröther's monograph on Photius (1869).

Photography, the art of producing pictures by means of the action of light on sensitised surfaces. It is usual to regard the observation by the alchemists of the 16th century that *Luna Cornea* or Horn Silver (native chloride of silver) is blackened on exposure to light, as the first chemical step in the history of photography, while the foundation of photographic optics was laid by Della Porta in the invention of the camera obscura (1569) at a somewhat earlier period. This property of chloride of silver, and also the darkening of nitrate of silver by light in the presence of organic matter, constitute the leading facts on which the science of photography is based. In 1777 the famous Swedish chemist Scheele found, by experiment, that Horn Silver was blackened quickest at the violet end of the solar spectrum, thus proving that the rays of light are not all alike chemically active. A quarter of a century later Ritter of Jena demonstrated the existence of chemically active non-visible rays beyond the violet rays of the spectrum.

The honour of having been the first to produce pictures by the action of light on a sensitive surface is now very generally conceded to Thomas Wedgwood, an account of whose researches was published in 1802 in the *Journal of the Royal Institution*, under the title, 'An Account of a Method of copying Paintings upon Glass, and of

making Profiles by the agency of Light upon Nitrate of Silver; with Observations by H. Davy.' The misfortune was that no attempts made either by Wedgwood or Davy to prevent the uncoloured portions from being acted on by light (or, as we now say, to *fix* the picture) were successful.

Nicéphore Niepce of Châlon-sur-Saône was the first to enjoy the satisfaction of producing *permanent* pictures by the influence of solar radiations. This was accomplished in 1814, and the name chosen to designate his process was Heliography. It consisted in coating a piece of plated silver or glass with asphaltum (bitumen). The plate so prepared was then exposed in the camera obscura for a length of time, varying from four to six hours. Wherever the light acted it rendered the asphaltum insoluble in its usual solvents. Hence, on subsequent treatment with one of these solvents, the shadows of the image dissolved away, and the lights were represented by the insoluble asphaltum remaining on the plate.

Daguerre appears to have begun in 1824 the experiments which eventually led to the discovery of the daguerreotype process. On Daguerre learning that Niepce was working in the same direction as himself, the two formed a partnership in 1829. The discovery of the Daguerreotype (q.v.) was announced in January 1839, but the details of the process were not made public till August of the same year. It consists in exposing a metal plate covered with iodide of silver for a suitable time in a photographic camera, the plate being afterwards transferred to a dark room, and exposed to the vapour of mercury, which develops the latent image, it being afterwards fixed. Although this process has become almost obsolete, it was really the first which was of any practical value, and experts all agree that no other known process renders some subjects —e.g. the human face—with such fidelity and beauty.

W. H. Fox Talbot read a paper to the Royal Society on 'Photogenic Drawings' on 31st January 1839, just six months previous to the publication of Daguerre's process. He produced these in this way: Writing-paper was steeped in a solution of common salt (chloride of sodium), and dried. It was then dipped in a solution of nitrate of silver, which is changed by the action of the common salt into the chloride of silver, some of the nitrate, however, remaining unaltered. Paper so treated is sensitive to light, so that when a fern-leaf, for example, is placed close down upon it between two plates of glass, and daylight is allowed to act on the prepared surface, the paper blackens except where it is covered, and thus a reversed picture of the leaf on a black ground is obtained. This was then placed over another sheet of paper, prepared in the same way, and the light allowed to act through it. Another picture of the leaf was thus produced, but this time with its lights and shades the same as in nature. The white image on a dark ground was called by Fox Talbot a negative, and the print from it he called a positive. These terms are still current in photography; the *negative* image being produced in the camera, as the first and leading operation—any number of *positives* being obtainable from it on paper, glass, or any other material capable of forming a support for a photographic image. The Calotype process was patented by Fox Talbot in 1841. In this process Talbot produced his negative by preparing paper on the surface with iodide of silver, subsequently washing it over with a mixture of nitrate of silver, with gallic and acetic acids, and then exposing it in the camera to the object he wished to copy. The invisible image or picture thus obtained was developed by aceto-nitrate of silver and gallic acid. The paper negative was then rendered translucent with wax, and used for the production of many positives in the way described above. The introduction of collodion by Archer marked the next great step in photographic progress, and this, known as the wet-plate process, has been almost eclipsed by the gelatine dry plate now almost universally used.

Photographic Apparatus.—The most important piece of apparatus used by the photographer is a form of the Camera Obscura (q.v.), generally called simply a camera, with its attached lens that throws the image on a ground glass screen placed at the back, to enable it to be sharply focused. A thin flat box with a shutter, together called a dark slide or 'back,' contains the sensitised plate. When the picture is focused the screen is withdrawn and the 'back' inserted in its place; the shutter is then drawn out, and the sensitised plate, which exactly occupies the place of the glass screen, being now exposed, receives the picture. In a brief time, which nowadays varies from a fraction of one to several seconds in a good light, the shutter is closed, and the slide returned to a room illuminated by a light not chemically active, generally red, orange or yellow green, where the plate is taken out and developed.

The introduction of dry plates for photography, which may be used in the camera a long time after their preparation, has had a great influence in modifying apparatus; and more especially is this true of the photographic camera. Under the older system (wet-plate photography) the plate had to be used immediately after it had been coated and furnished with its sensitive film, or it became useless. One dark slide or back, to hold the plate during exposure was therefore all that was necessary, for only one plate could be prepared and used at a time, a dark room or tent being necessary for the operations. But now that the plates will keep almost indefinitely between preparation and use, any convenient number can be made ready for insertion in the camera, to be exposed to the action of the light one after another. For this purpose what are called double dark backs are employed, each holding two plates—one on each side, and each side being furnished with a light-tight shutter which is drawn out so as to allow the lens to cast the image on the plate inside as soon as the back is fixed on the camera.

Much ingenuity has been applied to camera construction of late years, but, although many new modes of carrying the plates and bringing them under the influence of the lens have been devised, the double-back system, as just described, is the one most generally adopted when glass plates are employed. Various *changing-boxes* have been devised, which contain a dozen or more plates, and dispense with all but one dark slide, that is constructed to receive and discharge any plate of the series at will. Hare's changing-box is the one most generally known. This has a special form of dark back, which can be charged with one plate from the box at a time, and is then inserted in the camera for exposure. Recently, for small-sized photographs, a device has been largely adopted whereby the camera itself becomes a storage for the plates, a simple mechanical arrangement permitting the exposed plate to fall to the bottom while another takes its place.

But the most recent change in photographic apparatus is due to the introduction, or rather the revival, of sensitive films supported, not on glass, but on a flexible material. We have already seen that Fox Talbot employed paper for his negatives; and, although paper was superseded by glass when the collodion process came into existence, photographers were quick to recognise that such a brittle material had serious disadvantages. Many experimenters endeavoured to produce or find some

material which, while possessing the transparency of glass, should be of a less brittle nature, and among these Mr Woodbury in 1876 produced such a compound from collodion, castor-oil, and Canada balsam. This mixture, after being allowed to dry on a sheet of glass, was coated with an emulsion sensitive to light, and after again being dried was stripped from its support and cut into suitable sizes for the camera. It is noteworthy also that the inventor at the same time proposed that such films, being perfectly flexible, might be rolled and unrolled (panorama fashion), so that successive lengths might be submitted to the luminous image, and thus the whole business of changing plates be accomplished by the turn of a handle outside the apparatus. The same idea was taken up by Warnerke a few years later, and his patented *roller-slide* became obtainable commercially. Warnerke also made a sensitive dry collodion film for use in his apparatus, but its cost—which was at the rate of a penny per square inch—limited its use to a few.

To Messrs Morgan & Kidd of Richmond belong the honour of having first applied a gelatine emulsion to paper. This paper is now made by many dealers, and is commonly called bromide paper. Its principal use is for enlarging, but at the time of its introduction it was used for negative work, the paper being rendered semi-transparent by an after-operation. It must also be noted, too, that for this work the inventors employed a roller-slide of the kind suggested by Woodbury. The Eastman Company next took up the matter, introduced a roller-slide, together with a paper film of very reliable quality. This paper is sold in spools, ready wound, so that the buyer had merely to take a spool from its case, insert it in the roller-slide, and he immediately had material ready for reeling off forty or fifty negatives, to be subsequently separated by cutting, developed, and rendered transparent with a preparation of vaseline. These films were objected to by some on account of the trace of grain from the paper which was left on the picture printed from it, and a 'stripping film' was next adopted as previously proposed by the Rev. W. Palmer. By this modification the surface bearing the image could be stripped from the original paper and transferred to a stiff sheet of insoluble gelatine, which became its final support. Film photography has recently been brought to still greater perfection by the employment of transparent and flexible celluloid in sheet form. It is curious to note that this substance, invented by Parkes about 1855, was long ago proposed as an efficient substance for use in photography, and it would doubtless have been so used if collodion, when applied to it, had not had a solvent action. But as it is quite insoluble in water, it forms a perfect support for a gelatine film, and, now that it can be manufactured nearly as clear as glass, it represents the best thing yet introduced. Its general use is limited by its cost, which is greatly in excess of glass, but it presents so many advantages that it is very largely employed. The material is now made thin enough to be wound on spools and used in roll-holders. Beyond the advantage of lightness, portability, freedom from breakage, reduced cost of carriage, &c., which the films undoubtedly possess, there is one gain in their employment, of a technical nature, which is important enough to receive recognition here. They are free from halation. Halation is apparent in negatives taken upon glass plates as an encroachment of the light parts upon the dark portions, and is seen in its most aggravated form in the blurring out of windows in interior views. It is caused chiefly by reflection from the back surface of the glass.

The great rapidity of modern dry plates allows a photograph to be taken in such a mere fraction of a second that the camera can be held in the hand during the operation. Various hand-cameras are now made, and meet with extensive employment, especially by tourists, and are more or less disguised as despatch-boxes; but they are becoming so common that the disguise is more apparent than real.

The extreme sensitiveness of modern dry plates has also given rise to what is known as flash-light pictures, which are photographs taken by the almost instantaneous flash produced by scattering powdered magnesium into a lamp-flame. Many ingenious forms of lamps have been devised for this purpose. They mostly consist of a spirit-lamp in conjunction with a receptacle for the magnesium powder, with a pneumatic ball and tube attached. Pressure of the ball urges a puff of air into the powder, and carries it into the flame. This system is much used for taking groups and portraits at night in private and public rooms. The best workers employ a branch tube from the ball, which exposes the lens at the moment of maximum light.

Lenses.—The quality as well as the kind of lens used is of great importance. An explanation of the different forms and properties of Lenses is given under that head, but it is necessary to say a few words here about the kinds used in photography. They may be divided into two classes—portrait lenses, and view lenses. The former are of large aperture, but give a small image; while the latter have a small aperture, but give an image which covers a far larger surface. In the portrait lens rapidity of action has been the chief thing considered, for it is used in a studio where the amount of light available is always more or less limited. A portrait lens unless of the 'doublet' form is not suitable for view purposes; but a view lens can well be used for portraiture under certain conditions, and is one of the best lenses to use for groups. Under the head of view lenses come a large number which have fanciful names attached to them that are apt to mislead the tyro, but which are all more or less alike. In the early days of photography telescopic objectives were made to do duty in the camera, but they gave a very small field, and were in other respects unsuited to the purpose. Then came (1841) the portrait lens designed by Petzval, and made by Voigtlander of Vienna, an invention which marks an era in photographic progress. The single view lens, which is the cheapest and for pure landscape is still unequalled, had its first improvement in the patent aplanatic lens made by Grubb in 1857. Although called a single lens, it consists of a combination of crown glass of concavo-convex form, cemented to a flint divergent meniscus. The single lens was modified later on by Dallmeyer, who subsequently, in 1888, introduced a new form of view lens which, possessing the usual advantages, had the quality, hitherto unknown in a single landscape lens, of giving an image free from curvilinear distortion. The same feature had been secured by Dallmeyer in his well-known triplet lens, which was invented in 1860, and which, as its name implies, consisted of three combinations. This lens was serviceable for copying, architectural subjects, as well as for landscape, and was a great favourite with photographers. It has now been superseded by the doublet form of lens, which, under the name of rectilinear, symmetrical, &c., is the most commonly used form of photographic objective. It generally consists of two combinations of similar construction placed with their concave surfaces facing one another, the necessary stops or diaphragms for increasing definition and reducing spherical aberration being inserted in a slit in the brass mounting tube midway between them. These lenses are constructed to take different angles of view, according to the require-

ments of a given case: for taking subjects in a confined situation, such as a narrow street, or for depicting the façade of a large building at very limited range, a 'wide-angle' lens is necessary. For the convenience of those carrying a number of lenses, Ross has devised a series of 'symmetrical' lenses that all fit one flange. Every lens is sold with a set of diaphragms or stops; and, in the case of the lens last mentioned, these usually take the form of a rotating plate, pierced with the necessary apertures. But in other lenses the diaphragms are in the form of separate plates, and are kept in a small leather case by themselves, the operator removing any of the series, and inserting it in the lens when wanted. These diaphragms are marked with what is known as their focal value, which means that the number marked represents the fraction which the aperture of the diaphragm is of the focal length of the lens. To make this plain, let us suppose that the focal length of the lens is 6 inches, and that the diaphragm in question has an aperture of a quarter of an inch. As there are in 6 inches 24 of such quarter inches, the figure 24 will represent its value, and this will be expressed thus: $\frac{f}{24}$. In like manner, a half-inch diaphragm would be marked $\frac{f}{12}$, and a one-eighth inch diaphragm $\frac{f}{48}$. There is, however, another method of marking lens stops, which has been adopted by the Photographic Society of Great Britain, and which is called the 'Uniform Standard,' or U.S. for short. In this system $\frac{f}{4}$ is called No 1, and the U.S. number for any other size is found by dividing the focal length of the lens by the diameter of the opening as already described, squaring the result, and then dividing by 16. Of late years a remarkable improvement, which, however, had for some time been applied to microscopes, has been made in photographic lens diaphragms, in a contrivance which, from its resemblance to the natural diaphragm of the eye, which expands or contracts automatically according to the amount of light to which the organ is subjected, is called the iris diaphragm. This consists of a number of flat blades or tongues of thin blackened metal, which are fastened to a ring in the lens mount. By a turn of this ring the blades expand or contract, so that the aperture can be enlarged or diminished as required, while a scale marked on the outside of the lens mount, and a travelling pointer, indicate the focal value of every change of aperture. We may mention here one more important change in lens manufacture—the introduction of aluminium instead of brass for the necessary metal work, by which the weight of the instrument is greatly reduced. The same useful metal, only now rendered available by its cheaper manufacture, is also coming into use as a substitute for brass in the other metal fittings of cameras. A new kind of glass, known as Jena optical glass, is now being employed in the construction of photographic lenses. By its use a larger field can be covered with a given aperture than was the case under former conditions.

Wet-collodion Process.—Collodion (q.v.) is the name given to the solution of pyroxyline, a kind of gun-cotton, in a mixture of ether and alcohol. When this is flowed over a glass plate it gradually dries into a transparent film. It was first introduced for photographic purposes in 1851 by Mr Scott Archer, and has been of great and important service. For fully a quarter of a century the wet-collodion process was almost exclusively practised by photographers—in the earlier years for the production of positives on glass, and occasionally on leather or other non-fragile materials; latterly by modifications the process was more extensively employed for the production of negatives. Dry-collodion processes have also been in use, although on a much more limited scale. These are the stages in the wet-collodion process: (1) A glass plate made perfectly clean is coated with collodion, to which the bromide of cadmium and either iodide of potassium or iodide of ammonium have been added. (2) The collodionised plate is 'sensitised' by immersion in a bath of nitrate of silver, containing 35 grains to every ounce of distilled water. (3) Production of latent image by exposing the sensitised plate in the camera after the object has been focused. (4) Development of latent into visible image by flooding the plate with a solution of sulphate of iron (ferrous sulphate), or of pyrogallic acid, to either of which some acetic or citric acid is added. (5) Fixing of the permanent image by immersion of the plate in some solvent of those parts of the sensitive surface upon which the light has not acted. This solvent for wet plates is cyanide of potassium, but for more modern processes hyposulphite of soda is employed.

Dry-plate Processes.—It is hardly necessary to do more than name a few of the earlier dry-plate processes, since, except for experimental purposes, they have all been beaten out of the field by the recent one known as the gelatino-bromide process. Several advantages arise, especially for field-work, from using dry sensitive plates. With the wet process the operator, when away from his studio, must take with him a dark tent, collodion, a silver bath, and developing agents, besides a supply of water for washing purposes; but these *impedimenta* are not required with dry plates. Dry-plate processes are of two principal kinds: (1) Those in which the collodion is applied to the glass plate, and afterwards sensitised in the silver bath, as in the wet way, but with a 'preservative' such as albumen 'flowed' over the surface, and the plate allowed to dry. (2) Emulsion processes, in which the sensitive silver salt is held in suspension in the collodion or gelatine. A good emulsion can be prepared by adding some soluble bromide, such as bromide of cadmium, to the collodion, and afterwards an alcoholic solution of nitrate of silver. The glass plates are simply coated with this emulsion, washed in water to remove the soluble salts, and set aside to dry, when they are ready for use. The collodion emulsion process is still employed to a limited extent, chiefly for the production of transparencies; recent experiments indicate that it may yet compete with gelatine emulsion in sensitiveness.

The earliest form of the gelatino-bromide process, at present so universally employed, appears to be due to Dr Maddox, who published the details of a workable emulsion of this nature in 1871. The process was improved in 1873 by Mr Kennett, and again in 1878 by Mr Charles Bennett. It was found that if the emulsion was kept at a temperature of 90° F. for some days, or boiled for half an hour, the sensitiveness of the plate coated by it was so greatly increased that a view which could only be taken formerly in 30 seconds could now be taken in one. A very sensitive gelatine emulsion can also be formed by using ammonia along with the bromide of silver. Dry plates produced by some form of the gelatino-bromide process are now manufactured on a large scale. When properly made they will keep good for years, and they can be developed months after having been exposed. But it is generally admitted that the best results are obtained when the plates are not old, and when development follows exposure without undue delay.

Photographic Printing. *Silver Prints.*—The details of the well-known silver-printing process are briefly as follow:

(1) Suitable paper is coated on the surface with a smooth thin layer of albumen, to which chloride of sodium or of ammonium has been added. (Originally

the paper was salted only—i.e. the albumen was dispensed with—and this old method is being largely revived.)

(2) Silvering of the paper by floating it on a solution of nitrate of silver, from 30 to 60 grains of this substance being used for every ounce of water, according to the amount and kind of chloride in the paper. It is afterwards dried.

(3) Exposure to light. The silvered paper is exposed beneath the negative in a printing frame, the time of exposure varying according to the brightness of the light and the character of the negative.

(4) Toning. In order to give a pleasing colour to the print it is usual to tone it in a solution of chloride of gold. Quite recently the metal platinum has been used for toning silver prints on plain paper with very fine results. One method has been introduced by Blanchard, and another by Lyonel Clark, the latter employing the same salt, the chloro-platinite of potassium, which is used for the platinum printing process to be presently described.

(5) Fixing. The print, when taken from the toning bath, is steeped in a solution of hyposulphite of soda, which removes the undarkened silver salt that is still sensitive to light, and so fixes the image.

(6) Washing. Silver prints require to be washed quickly and thoroughly after treatment with the hyposulphite of soda. Prolonged soaking is harmful, and imperfectly washed prints soon spot and fade. Gelatine is now largely coming into use as a substitute for albumen: it is more suitable for the rendering of delicate detail, and the prints with due care exercised in their production ought to be more permanent. The papers known as Aristotype, Argentotype, and Celerotype are gelatine emulsions of chloride of silver spread on paper.

Printing in Salts of Iron.—The metal iron in some of its chemical preparations is now very largely employed in a number of photographic printing processes—e.g. cyanotype, chrysotype, kallitype, platinotype, &c.—and is capable of producing results with all the fidelity and delicacy of the silver process, in some cases at considerably less cost, while the manipulations are greatly simplified. There are certain preparations of iron, known as *ferric* salts, that are not affected in appearance when certain other chemicals are brought in contact with them; other preparations of iron, known as *ferrous* salts, produce highly-coloured pigments when combined with these same chemicals.

The action of light can change ferr*ic* into ferr*ous* salts; hence, if a piece of paper be coated with a ferric salt, dried, and placed under a fern leaf, a piece of lace, or a photographic negative, and exposed to light, an image in a ferrous salt is produced which is capable of being developed into a highly-coloured image when acted on by a suitable reagent; and not only so, but, as this reagent has no action on the ferric salt, they may be mixed together in the first instance and thus applied to the paper, when the action of light will develop the highly-coloured image, a simple wash in water completing the operation. This is in outline what is known as the *Cyanotype or Blue printing* process, first published by Sir J. F. W. Herschel in 1842, which in detail is as follows:

Two solutions are made up, one containing sixty-four grains of ammonio-citrate of iron to the ounce of water, the other forty-eight grains of ferricyanide of potassium to the ounce of water. Mix equal quantities of these solutions, and with a soft sponge or flat camel-hair brush quickly and evenly cover one side of good smooth white paper. This is best done by gas or candle light; then place to dry where it will not be affected by daylight. The paper so prepared is chiefly used for copying plans and drawings on tracing cloth: the tracing, which should be in a good opaque black ink, is placed on the top of the paper, and both are covered with a glass plate to keep them in perfect contact. Ten minutes in a very bright light will suffice for exposure. The print is now washed, when the lines of the drawing will appear white on a blue ground. The same kind of paper can be exposed beneath a photographic negative in order to secure a rough proof of the picture, but in this case the time of exposure is much increased. A disadvantage of the above process is that the original black drawing on white paper appears as a white drawing on a dark-blue ground.

The following modification, known as the Pellet process, produces blue prints on white paper: Gum arabic, 25 parts; common salt, 3 parts; perchloride of iron, 8 parts; tartaric acid, 4 parts; and water to make up to 100 parts. Well-sized paper is coated with the above and treated as in the preceding; it is very sensitive to light. A good tracing in bright sunlight is sufficiently printed in from ten to fifteen seconds. The print is developed by immersion in a saturated solution of ferrocyanide of potassium (yellow prussiate), and the design immediately appears in blue. The print is now rinsed in cold water, and then transferred to a 10 per cent. solution of hydrochloric acid; another rinse in cold water completes the operation.

Chrysotype.—This is a modification of cyanotype, also published by Sir J. Herschel. The paper is merely coated with the ferric ammonium citrate, and may be developed after exposure with a neutral solution of gold chloride, washed with water and dried. The resulting print is in metallic gold in a finely-divided state, and is of a fine purple colour. A dilute solution of nitrate of silver may be substituted for the gold when the image is in metallic silver.

Kallitype.—In this process paper is washed with a strong solution of neutral ferric oxalate. After printing in the usual way, it is developed by the following solution: Nitrate of silver, 50 grains; citrate of potash, 800 grains; bichromate of potassium, 1 to 2 grains; rain water, 10 ounces. The precipitate formed is next dissolved by the addition of ammonia (strength, ·880)—about a drachm will be sufficient. After filtering add 35 drops of strong nitric acid, and the developer is ready. This solution is very cheap and easily prepared. The resulting prints possess a fine rich black colour.

Platinotype, or Platinum Printing Process.—The metal platinum can be deposited from some of its chemical preparations in an extremely fine black powder when brought in contact with one of the iron salts altered by light. Herschel explained how to get prints in platinum, but the process now employed is that discovered by Willis. Captain Abney, F.R.S., thus describes the chemical action upon which the process is based: 'Mr W. Willis, jun., found that he could obtain an image in platinum black, by means of development, if he sensitised his paper with ferric oxalate, with which was mixed a solution of chloro-platinite of potassium. The action of light on this paper is to reduce the ferric salt to the ferrous state, and when the ferrous salt is in solution the platinous salt is reduced by it. By floating the exposed paper on a solution of neutral potassium oxalate, which is a solvent of the ferrous oxalate, the platinum salt in contact with it is immediately reduced to the metallic state, and an image is thus built up. To fix the prints they are immersed in dilute hydrochloric acid, which dissolves away any ferric oxalate there may be, and also gets rid of any oxalate of lime.'

Paper prepared as above described is supplied com-

mercially. And after being exposed to light beneath a negative in a printing-frame for about one-third of the time necessary in the case of a print on silvered paper, its lemon-yellow tint is found to change, where the light has reached it, to a pale, dirty-gray colour. Development is conducted in an iron enamelled tray, beneath which a spirit-lamp or bunsen burner is placed, so as to keep the oxalate solution at a temperature of about 175° F. Under-exposed prints will benefit by this temperature being exceeded, whilst those which have received more light than they should have had can be advantageously treated with a much colder developer. The print is floated on this warm bath, which turns the faint image of the picture to a dense black, and fixation follows by placing the picture in a series of water baths made slightly acid with hydrochloric acid; these remove the iron from the paper; a simple rinse in plain water completes the operation. The developer can be mixed in bulk, for it keeps well, and the same quantity will develop a large number of prints one after the other. The platinum prepared paper will keep well if damp be excluded. For this reason it is sold in tin tubes, which have at one end a small quantity of calcium chloride, a salt which is so greedy of moisture that it will absorb all in its neighbourhood. The favour with which this process has been received, because of its permanence and its quick results, is well indicated at photographic exhibitions, where a large proportion of the pictures shown are invariably platinotypes. Mr Willis, the inventor, has introduced a *cold* bath platinum process, in which the metallic salt is contained in the developer, and this modified method is said to present many advantages. The developer thus prepared is not of a lasting kind, and only enough must be mixed to meet the existing demand. Another modification of the platinum process, made known by Willis, but more generally associated with the name of Captain Pizzighelli, yields a dark image in the printing-frame. The only necessary after-treatment is a bath of weak acid, followed by washing in plain water. There is every reason to suppose that platinum will be the printing process of the future, but unfortunately the price of the metal, which in 1890 went up more than 100 per cent., is calculated for the present to limit its use.

Bichromated Gelatine Process.—So far back as 1839 Mungo Ponton announced that paper steeped in bichromate of potash and dried changed its colour when exposed to light. It was subsequently discovered that light not only alters the composition of the bichromate, but also oxidises the size (gelatine) of the paper. Gum, starch, and albumen were also found to become, like gelatine, insoluble when exposed in contact with the bichromate of potash or ammonia to the action of light. If ordinary gelatine be soaked in cold water, it absorbs the water and swells, and then if heated, or if hot water be poured on it, the gelatine melts. If some bichromate of potassium or ammonium had been added to the cold water, the gelatine would absorb the chemical along with the water. If now the gelatine be dried and exposed to light until the stain imparted by the bichromate is altered in colour, it will no longer swell in cold water, neither will it dissolve in hot water; the action of light has made the bichromated gelatine insoluble. It is to gelatine thus chemically modified that we owe the 'autotype' or 'carbon'—more correctly 'pigmented gelatine'—process. The Collotype, Woodburytype, and some forms of photozinco engraving and photogravure, also certain kinds of 'phantom' photographs, and one method for vitro enamels, depend on the same principle.

The Autotype, Carbon, or Pigmented Gelatine Process.—Pigmented gelatine paper is an article of commerce, and the Autotype Company supply this 'tissue' sensitised ready for printing. The tissue consists of a thick coat of gelatine, with which has been intimately mixed a certain amount of permanent pigment in very fine powder—if for a black, Indian ink may be employed; other colours are added to modify the tint. The paper so coated is sensitised with ammonium bichromate, and then exposed under a negative till it is supposed to be sufficiently printed. The image is not visible as in a silver or iron print, therefore some indirect plan of telling the proper time of exposure, such as by the use of an actinometer, must be resorted to. The change which takes place in the gelatine film is this: the surface next the negative has been rendered insoluble wherever the light has acted, and that to a depth corresponding to the intensity of the light. It results from this that almost the whole of the surface of the gelatine has been rendered insoluble—to the greatest depth where the light has acted most strongly. Soluble portions, however, remain enclosed between its surface and the paper. No picture is visible till these are removed. To overcome this difficulty—the removal of the soluble portions imprisoned between the insoluble skin and the paper at the back—took many years of experimenting, and all sorts of devices were resorted to. One plan was to expose the back of the tissue to the negative, thus printing through the paper, but the grain of the paper showed offensively. Fargier spread the pigmented gelatine on glass, exposed it thus under a negative, and then coated the film with collodion. On subjecting the whole to the action of warm water, the latter penetrated the collodion and softened the gelatine, which eventually floated off the glass, being held together by the collodion. This was now supported on paper (collodion side down), and washed from the back with warm water, and so the first half-tone photographs in pigmented gelatine were obtained.

Swan experimented on similar lines, and in 1862 he took out a patent for pigmented gelatine films spread upon collodion supported on glass. When dry the whole was stripped from the glass, and thus the first tissue was made. The difficulty of removing the entangled pigment still remained, and this Swan overcame by coating the collodion surface of his tissue with india-rubber solution, and applying it to a piece of paper similarly coated. When both were dry the whole was passed through a press, and then soaked in warm water; thus the soluble portions could be removed, leaving that part of the film acted on by light untouched, and projecting *in relief* according to the varying action of light as it passed through the gradations of the negative. By this method and a subsequent modification Swan sent out a number of fine pigment prints, but it was so troublesome, expensive, and unsatisfactory in the hands of the average photographic printer that printing by bichromated gelatine never became popular until J. R. Johnson, about the close of the year 1868, discovered that the pigmented gelatine paper ('autotype tissue'), when sensitised by the bichromate and correctly exposed to light under a negative, only required to be soaked in cold water, and then evenly applied to *any surface impervious to air*, such as glass, zinc, oilcloth, &c., when the gelatine surface would adhere very tenaciously to the support—after the principle of the schoolboy's sucker—by atmospheric pressure alone. Then by soaking in hot water the paper at the back came off, carrying with it much of the unaltered pigment and gelatine, and by laving the image remaining on the support with the hot water the picture in all its delicate gradations appeared clean and perfect. It was this

discovery that made what is generally known as autotype or carbon printing a practical working process. The method above described is called the single transfer process, and produces a print reversed as to right and left. The double transfer process merely differs in the adoption of a temporary support of opal glass, zinc, or paper coated with a suitable preparation (the most convenient being Sawyer's flexible support), which holds the print till developed, and from which the print is then transferred to its final support—it is then non-reversed. When practicable it is usual to take a reversed negative, and thus avoid the double transfer.

Powder Process.—By what is called the powder process prints are produced on paper in plumbago, or any other impalpable powder insoluble in water. It has been a good deal used on the Continent. A slightly sticky or 'tacky' preparation of sugar, gum, glycerine, and potassium bichromate, when exposed to light, loses its tackiness in proportion to the intensity of the light acting on it. A glass plate coated with this preparation will therefore, when exposed under a negative, represent the picture, so to speak, by different degrees of tackiness. In this state a fine powder sprinkled over it will adhere in proportion to the stickiness of the surface. When the superfluous powder is removed, and the film coated with tough collodion, it can be detached and, if required, put on any support such as paper, but the soluble portion of the gum, &c. is previously removed by washing.

Photographic Enamels on Glass and Porcelain.—If the image as described in the preceding paragraph be developed by suitable metallic oxides —such as the underglaze colours of the porcelain painter—and the resulting image coated with collodion be washed, the film can be transferred to glass, china, or enamelled metal, and after firing in a suitable kiln it will become vitrified, and will be as permanent as a burnt-in painting on the same substances. Some of the very finest vitro enamels are, however, produced by a 'substitution' process, in which a collodion transparency is toned to saturation with platinum, or iridium, all traces of silver being carefully eliminated. This modified film is now transferred to an enamel tablet, and burnt in as in the previous method.

Diazotype.—A new colouring matter or dye of a primrose tint was discovered by Arthur G. Green in 1887, who named it 'primuline.' This dye affixes itself very tenaciously to cotton fibre, so that by merely boiling the fabric in its aqueous solution a permanent yellow colour results; and this yellow basis acts as a mordant, permitting, when acted on by appropriate developing agents, the building up of an immense variety of 'ingrain colours' that admit of wide practical use.

By passing the yellow cloth through a bath of acetic acid and nitrate of soda the material is said to be 'diazotised,' and then is of a brighter yellow colour that is extremely fugitive under the influence of light. This constituted for a time an insuperable objection to its use as a dye, but suggested photographic possibilities. Experiments proved that, if a material containing diazotised primuline be exposed to light under a design, those parts acted on by light speedily decomposed, while the parts protected remained unaltered; the latter on treatment with a phenol or amine produce many permanent compound colours, and the former remain unchanged. Upon this is founded the diazotype process, by means of which every kind of fabric, cotton, muslin, velveteen, wool, linen, silk, &c., as well as colloid films and paper, are dyed by the influence of light. The process is exceedingly simple, very cheap, and gives a *positive* print, the most opaque objects or parts of a design coming out darkest, the reverse being the case in ordinary silver printing.

Mr Green, in conjunction with his partners Messrs Cross and Bevan, published the process at a meeting of the British Association at Leeds in 1890.

Mechanical Printing. *Woodburytype and Stannotype Processes.*—It has long been known that if a leaf, a bit of lace, or any similar object was placed on a sheet of soft metal, and considerable pressure applied, the impression of leaf or lace was sunk into the metal. From this metal plate prints were taken as from an engraved plate, and the process was called Nature-printing (q.v.). If we laid an ordinary autotype print instead of a leaf on a flat piece of iron, covering it at the same time with a smooth piece of sheet-lead, and then put them under sufficient pressure, the result would be an imperfect Woodburytype mould in the soft lead. The metal reverse would be faulty, because in this case the gelatine film is too thin to give enough of relief. In order to obtain a proper mould a layer of sensitised gelatine, considerably thicker than that used for an autotype print, is exposed under a negative. It is developed as in the autotype process, and presents the image in considerable relief. The print is then covered with the lead, and they are pressed together in a hydraulic press, which produces a reverse or mould of the picture in the soft metal without injuring the gelatine relief.

The production of ordinary Woodburytype prints is a purely mechanical operation, the chemical action of light not being called into play; they exhibit true gradation of tint, and in that respect Woodburytype is the only perfect photo-mechanical printing process known. The mould is placed in a printing-press of a peculiar but simple construction, and a warm solution of pigmented gelatine forms, so to speak, the printing-ink. This is poured on the mould, and a thin, hard, strongly-sized paper placed on the top of it. The lid of the press has beneath it a perfectly flat glass plate, which is now brought down on the mould and the lid firmly locked by a catch. The pressure causes all the superfluous gelatine to exude, whilst that in the mould adheres to the paper. In a short time the gelatine sets, when the plate is raised and the print withdrawn. It has now only to be placed in a solution of alum, which renders the gelatine forming the picture insoluble.

The Stannotype (or printing from a surface of tin) has been called a simplified Woodburytype process. Mr Woodbury, to whom it also is due, thus describes it: 'A positive is first made from the negative—preferably by the carbon process. From this carbon or other transparency a negative is made also in carbon; but in this case the tissue possesses much more body and much less colour, so as to obtain a certain amount of relief. This (gelatine) relief negative is then coated with a thin india-rubber varnish. A piece of tinfoil is laid over it, and the whole passed through a pair of india-rubber rollers—a species of mangle, in fact. We have now a printing-mould ready for placing in the press and printing from in gelatinous ink.' This process does not always give the beautiful results obtainable by the original Woodburytype method, but remarkably good results are secured by it.

Heliotype and Phototype Processes.—Both of these are photo-mechanical methods, in which the gelatine relief is itself used to print from in some form of printing-press, instead of being covered with tinfoil as in the stannotype process. Lithographic ink is used. The film or layer of gelatine forming the printing surface requires to be specially and carefully prepared. This process, under the name of Collotype, is much used for book illustration and advertising purposes.

Photo-lithography and Zincography.—The only difference between these is that a lithographic stone is used in the one case and a plate of zinc in the other for the mechanical printing. It is necessary that the original drawings should be done in lines and not in half-tint. At least, it is doubtful whether much success has as yet attended the production of half-tint photo-lithographs. A negative is taken from the drawing by the camera, and from it a print is made on paper coated with bichromatised gelatine much in the same way as in the autotype process. But before the print is developed it receives a coating of lithographic transfer ink specially prepared for the purpose. It is next floated in warm water till the lines are seen as depressions. With the aid of a sponge and water at a temperature of about 150° F. the soluble portion is removed, leaving the picture in insoluble gelatine with its coating of transfer ink. It now only requires to be washed, dried, and transferred to the stone or zinc plate (see LITHOGRAPHY). These processes have been greatly superseded by the various photo-engraving and zinc processes, fully described in the article ILLUSTRATION, by which printing blocks suitable for a typographic press can be produced in a few hours.

Photography is generally employed as a means of reproducing drawings on wood blocks for the engraver. This process is of much importance, as the original drawing is preserved, not only for comparison with the finished engraving, but it may be for its artistic value. The original drawing also may be made of any convenient size, and reduced on the wood—a great consideration when minute objects are to be represented. The necessities of wood-engraving require that the drawing-on-wood should be reversed; hence the necessity of a reversed negative in any direct printing process. The negative may either be printed direct on to the wood, or a modification of the carbon process employed. In the first case, one process is first to render the surface of the block waterproof, and then it is whitened with Chinese white. The block is then sensitised with chloride of silver, and printed under a reversed negative. It is then toned with gold and fixed with hyposulphite of soda, washed and dried, and is then ready for the engraver.

In the carbon process, a carbon tissue is made with very little gelatine and a large amount of carbon or other pigment. The block is rendered waterproof and whitened with baryta; the carbon print is developed on the wood with warm water, and, when dry, is ready for the engraver.

Photo-micrography consists in photographing microscopic objects by causing a microscope to take the place of the ordinary photographic lens in the camera, so that the enlarged image is cast upon the sensitive surface of the collodionised or gelatine plate. Such photographs, again enlarged by the optical lantern, are much used for class instruction.

By reversing the arrangement necessary for the enlargement of microscopic objects it will be seen that minute photographs of engravings, or other objects, may be produced which would require a microscope for their inspection. In this way communication was maintained during the investment of Paris, when copies of letters and newspapers were inserted in quills, and fastened to carrier pigeons.

ASTRONOMICAL PHOTOGRAPHY.—The application of photography to astronomy has within the past few years assumed immense importance, and great results have been achieved through the wedding of the camera with the telescope. Until recent times the only remarkable photographs of the celestial bodies were those of the moon, which were executed by Warren de la Rue, Rutherford, and others. The moon being from its size and brightness a comparatively easy body to photograph, the old processes were sufficient for the purpose, and most perfect results were obtained. Jansen and others have secured photographs of the sun which exhibit markings upon its surface with great distinctness, and many photographs of the corona when the orb has been under eclipse have been taken when the somewhat rare opportunity has occurred. But it is in picturing the distant stars and nebulæ that the greatest work has been achieved by photography, and results obtained which would have been impossible without the aid of the highly sensitive dry plates now at the disposal of the astronomer. Among the triumphs already obtained in this direction may be mentioned Roberts' photograph of the 'Andromeda Nebula,' Common's photograph of the Nebula in Orion, and several similar negatives obtained by the brothers Henry of Paris. One by these last workers, a photograph of the Pleiades, should receive special mention. A certain star in this well-known group appeared in the photograph in question with a nebulous haze attached to it. This star was not known to be associated with a nebula, and the astronomers of Paris in vain endeavoured to detect it by aid of the most powerful telescope at their disposal. The nebulous mass was therefore discredited, until another photograph of the Pleiades arrived shortly afterwards from America which exhibited exactly the same peculiarity. Once more the nebula was searched for, and at length was declared to be faintly discernible. From this it would seem that the photographic film is more sensitive to faint impressions than is the retina of the eye, and in a certain sense this is true. These star photographs are often exposed to the action of the light from those distant bodies for three or four hours, during which time the clock-work train attached to the telescope keeps the images of the tiny points of light stationary on the plate, in opposition to the rotation of the earth. Each image, however faint, has therefore a comparatively long time to make an impression on the sensitive chemical surface, and exerts a cumulative action, with the result that the images of stars are registered which no human eye has ever beheld. To put the matter more plainly, it may be said that a certain section of the sky covered by the field of a powerful telescope is seen to contain a definite number of stars. When this same space is photographed their number is often doubled. At a convention of astronomers held in Paris in 1887 it was decided to take steps for photographing the whole of the heavens. For this purpose the sky has been chartered out into squares, and each observatory helping in the work will photograph a certain number of these spaces. The work is estimated to entail ten years' labour, this long time being partly accounted for by the circumstance that, owing to the occurrence of unsuitable weather and the interruptions caused by moonlight, there are only about fifty nights in the year when sidereal photography is possible. There are many difficulties in photographing the stars, some of which have led to discussion, and have caused doubts to be raised as to the accuracy of the results attained. The chief of these is represented by the circumstance that the photographs exhibit discs of light, varying in size according to the brightness of the stars, instead of mere points of light, which the extreme distance of the bodies should secure. This expansion of size is believed to be due to irradiation, want of complete achromatism in the lenses, and reflection from the back of the photographic plate. These difficulties will no doubt be surmounted in the future, and it may be mentioned

that they are only observable when a refracting telescope is employed. Hence the use of reflecting telescopes for this work has been suggested; but, although by this means some of the faults mentioned are banished, other inconveniences arise which form obstacles to good work. Dr Huggins has done much valuable work in photographing the spectra of the heavenly bodies.

Durability of Photographic Prints.—Experience has proved that silver prints, however carefully prepared, cannot be depended upon for permanency. Much vexation has frequently arisen from the fading of these, and on this account they are no longer used for book illustration. They will keep better unmounted than mounted, and they should be kept in a dry situation, as damp increases their tendency to fade. Platinotype prints are believed to be permanent by those best able to judge. Autotype, Woodburytype, and other prints in pigmented gelatine are permanent if stable colours are employed, and of course those obtained by any of the photo-mechanical processes are certainly so when printed, as they usually are, in lithographic or printers' ink.

Miscellaneous Applications and Improvements.—The report that the art of photographing in the colours of nature has been discovered crops up year after year with curious persistency, and may be generally traced to the work of unscrupulous persons who seek to deceive the public for their own advantage. It is difficult to see how the much-talked-of photography in colours as popularly understood can ever be achieved. By the introduction of specially prepared gelatine dry plates—known as *orthochromatic* ('right colour') or *isochromatic* ('equal colour'), both very vague terms—it is possible to reproduce colours in their true shade relation to one another. For instance, suppose that one seeks to photograph by ordinary plates a blue vase containing yellow flowers. In the resulting picture the vase will be white and the flowers will be black. But if we use isochromatic plates the vase will be rendered as a gray and the flowers will appear almost white, which is obviously more true to the way in which the eye observes the original. This change in the behaviour of the sensitive surface is brought about by adding to the gelatine emulsion of which it is composed a minute quantity of certain dyes. Vogel in 1873 discovered that certain coal-tar dyes produce a change of sensitiveness in silver compounds; and in the same year Tailfer and Clayton secured a patent for the preparation of colour-sensitive plates prepared by the same agency. They use an ammoniacal solution of eosine; and plates made under the patent are now supplied commercially. They are much used in copying all coloured objects, such as oil-paintings; and there is little doubt that they will play an important part in sidereal photography, in the registration of coloured stars. Meteorologists are now depending upon photography to furnish them with cloud studies, and with pictures of Lightning (q.v.). A study of the latter is likely to extend our knowledge concerning the phenomena connected with thunderstorms, and has already elucidated a few problems. Muybridge, in the United States, introduced the system of analysing by means of photography the motions of a trotting horse, running dog, &c. By means of special apparatus he found it possible to take a dozen consecutive pictures of a single movement. Marey of Paris further developed this phase. In the cinematograph a series of photographs taken in rapid succession from a moving scene is thrown on a screen by the aid of a magic-lantern in the same rapid manner in which they were taken, the result being a life-like reproduction of the original scene.

Photography through an opaque object by means of the Röntgen rays (see RÖNTGEN) has already been of immense use in surgery in fixing the exact position of bullets, &c., in the human body as a preliminary to their extraction.

Although photography in colours has long occupied the attention of scientific photographers, no direct method of doing so has yet been described. One, and perhaps the most important of the indirect methods, is as follows: Three separate (colourless) negatives of a coloured object are taken through coloured screens. From these positives are taken, and colour is supplied by means of inks or dyes. When these three-coloured monochromatic positives are superimposed, and seen by projection on a screen or through a photo-chromoscope, a coloured image of the original is the result.

Photogravure. By this process the finest possible results are obtained, but the expense of producing pictures by its aid, which is akin to the operation of copperplate printing, limits its use to high-class book-work. It is also used by Boussod, Valadon & Co., by Durand of Paris, by the Autotype Company, by Messrs Annan & Swan of Glasgow, and others for the production of large pictures which rival the finest steel engravings in their delicacy and finish. Photographs can be reproduced in this form, but the process seems to be more largely employed for obtaining engraving-like copies of celebrated pictures. The process is so perfect that every touch of the painter's brush is clearly seen in the copy, and even the upstanding ridges of paint in the bolder touches are rigidly reproduced. There are naturally different ways by which printing plates for use in this process are made, and a brief description of two methods only must here suffice to give an indication of the line of operations. (1) A gelatine relief is obtained by exposing bichromated gelatine to the action of light beneath a negative. But the gelatine employed is mingled with a certain quantity of graphite (black lead) in a more or less granular form. This addition causes the resulting relief to have a surface which is granular in character, and which is also a conducting one to electricity. If therefore the relief be placed in an electrotype bath it will speedily become covered with a deposit of copper. From the copper plate so formed copies on paper can be obtained by the usual copperplate printing process. (2) A bichromated gelatine print —negative in character—is developed upon the specially prepared surface of a copper plate, which is then subjected to the action of a solution of perchloride of iron. This penetrates the gelatine more or less quickly according to its varying thickness, and then attacks the copper, which is eaten away by the chemical action that ensues. Thus in the end the copper plate bears on its surface an etched image, penetrating more or less in depth according to the shadows and lights of the gelatine image previously affixed to it. The plate is next 'steel'-faced and printed in the copperplate press. (It is often necessary to resort to hand-finishing in order to get the finest results.)

Photometry (Gr. *phōs*, 'light,' and *metron*, 'measure'), the art of measuring the intensity of a source of light, by comparison with a standard of reference (see GAS-LIGHTING). The principles involved in the usual instruments are: (1) Lambert (1760), Rumford: equality of shadows cast by two sources at different distances; when the shadows are equal the intensities are proportional to the squares of the distances. (2) Equality of illumination through slits in screens; distances and intensities as before. (3) Bouguer, Ritchie, Leonhard Weber: reflection of light from two sources, so that they travel side by side to the eye, the distances being adjusted until they appear equal; calculation as before. (4) Wheatstone, the same; but the two reflections are from a polished sphere, which is set in motion, so that the comparison is between two looped luminous curves, produced through the persistence of vision. (5) Bunsen: a grease-spot on paper, equally illuminated on both sides, disappears. (6) Babinet: light from one is polarised by reflection, from the other by refraction; both pencils are sent through a double rotating quartz, and looked at through a double-refracting prism; they give coloured images, and the distances are adjusted until the images, on over-lapping, give a white field. All these methods are unsatisfactory when the sources of light are of different colours, as—e.g. a candle and an arc-lamp. Instruments have accordingly been devised for applying the above methods to each part of the spectrum of the light from each source. The degree of sensitiveness of the eye of the observer, or a difference of sensitiveness between his two eyes, affects the result. In other instruments used as photometers what is measured is not the luminous intensity so much as the radiation: among these we may mention the Radiometer (q.v.); Leslie's photometer, which is a differential thermometer; Bunsen and Roscoe's, which measures the quantity of hydrochloric acid formed in a given time from chlorine and hydrogen; Léon's, which measures the amount of nitrogen liberated from iodide of nitrogen; and various instruments based on photographic reactions, which truly measure not the luminous, but the actinic intensity. Stellar photometry is generally contrived by stopping off more or less of the surface of the object-glass, or by polarising apparatus, so as to bring the apparent brightness of a star down to that of a standard of comparison. The usual photometric standards are (1) the English standard candle (see GAS-LIGHTING); (2) the Hefner-Alteneck amyl-acetate lamp, which has now displaced the candle in Germany; (3) the carcel, a standard colza-oil lamp, used in France; (4) the Electrical Standards Committee's unit, the light given off by one square centimetre of platinum at its fusing-point; and (5), in scientific work, an incandescent electric-lamp under stated conditions of resistance and current, maintained constant.

Photophone is the name of a comparatively simple apparatus which may be said to achieve the feat of transmitting articulate speech to a distance along a beam of light. It was first described in 1880 by Professor Graham Bell, known in connection with the telephone, at the Boston meeting of the American Association; but already in 1878 its inventor had announced the possibility of 'hearing a shadow' by means of a similar agency. The success of the photophone depends on the peculiarities of the metal selenium. Crystalline selenium offers a high degree of resistance to the passage of an electric current; it is eminently sensitive to light; and the resistance is less when exposed to light than in the dark, being in some cases only a fifteenth in the light of what it is in the dark.

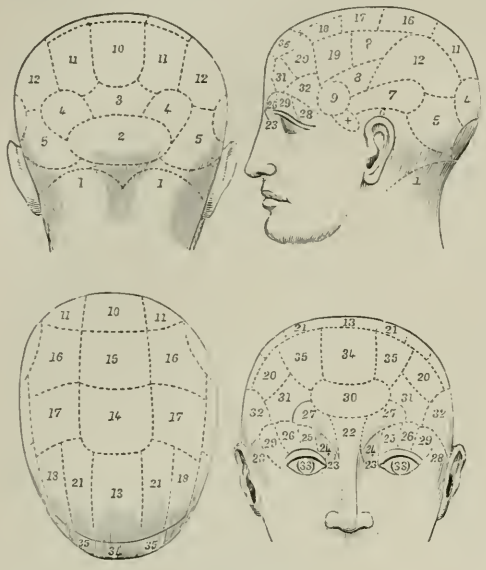
Founding on these peculiarities, Professor Graham Bell, his friends, and assistants devised some fifty forms of apparatus, for so varying the transmission of light to prepared selenium as to produce audible sound. In the photophone found most serviceable the transmitter is a plane mirror of silvered microscope glass or thin mica; the receiver, fixed at a distance without any connection, is a parabolic reflecting mirror, in the focus of which is placed a sensitive selenium 'cell,' connected in local circuit with a battery and telephone. When the apparatus is used, a strong beam of light is concentrated by a lens in the plane mirror; the speaker directs his voice against the back of this mirror, which is thrown into vibrations corresponding with those of the voice. The reflected beam of light, to which corresponding vibrations are also communicated, is directed through a lens to the receiving mirror, and creates in the selenium cell a rapidly variable current, which at the end of the telephone attached becomes audible again as vocal sound. When first described, the photophone had been used effectively with a distance of 230 yards (over a furlong) between transmitter and receiver. The rays of the oxyhydrogen light, or of an ordinary kerosene lamp, suffice for transmitting articulate speech. The loudest sounds obtained from the photophone were produced by means of a perforated disc, noiselessly revolving so as rapidly to interrupt the light in transmission.

It was also found that a very audible sound could be procured from the selenium without the aid of telephone and battery. A beam of intermittent light will produce a strong musical note from the selenium. Further experiment showed that selenium is not the only substance thus sensitive to light. Still louder sounds than these obtained from the selenium directly, though not articulate, were got from diaphragms of hard india-rubber and of antimony; and sounds of varying intensity were given out by many other substances, including gold, silver, platinum, copper, zinc, lead, paper, parchment, and wood.

Photosphere. See SUN.

Phrenology (Gr., 'a discourse on the mind') was the name given about 1815 to the theory of mental philosophy founded on the observation and discovery of the functions of the brain concerned in intellectual and emotional phenomena, as formulated by Gall (q.v.). In Britain the system was amply expounded by Gall's pupil Spurzheim (q.v.), by George and Andrew Combe (q.v.), and by Dr Elliotson, founder and first president of the Phrenological Society; and in America by Dr Charles Caldwell of Kentucky, the brothers Fowler, and S. R. Wells. The connection of mind and brain was an old theory, and a kind of localisation of mental function in the brain had at various times been attempted from the days of Albertus Magnus downwards; but the first full-fledged system of empirical cranioscopy or phrenology must be attributed to Gall, who established his scheme by inspecting the exterior of the heads of a considerable number of persons of different characters; and believing himself to find portions of the scalp corresponding to their mental and moral faculties, marked out on a model of the head the areas which were prominent in proportion to the strength of the various faculties. These faculties were by Spurzheim divided into two orders—Feelings and Intellect, or Affective and Intellectual Faculties. The Feelings were divided into two genera—the *Propensities* and the *Sentiments;* while the Intellectual embraced the *Perceptive* or *Knowing* and the *Reflective Faculties.* Various modifications of Gall's scheme of localising the faculties were made by his pupils. American phrenologists (the Fowlers and S. R. Wells) increased the number of the faculties to

forty-three; dividing the affective series into the domestic, selfish, moral, and self-perfecting groups, and the intellectual into the perceptive and reflective groups. The following is a representation of the human head from four points of view, showing the positions of the cerebral organs, according to Spurzheim and Combe:



AFFECTIVE.

I.—Propensities.

1. Amativeness.
2. Philoprogenitiveness.
3. Inhabitiveness or Concentrativeness.
4. Adhesiveness.
5. Combativeness.
6. Destructiveness and Alimentiveness.
7. Secretiveness.
8. Acquisitiveness.
9. Constructiveness.

II.—Sentiments.

10. Self-esteem.
11. Love of Approbation.
12. Cautiousness.
13. Benevolence.
14. Veneration.
15. Firmness.
16. Conscientiousness.
17. Hope.
18. Wonder.
19. Ideality.
20. Wit. 21. Imitation.

INTELLECTUAL.

I.—Perceptive.

22. Individuality.
23. Form.
24. Size.
25. Weight.
26. Colouring.
27. Locality.
28. Number.
29. Order.
30. Eventuality.
31. Time. 32 Tune.
33. Language.

II.—Reflective.

34. Comparison.
35. Causality.

The new science made many converts and became popular in most European countries. By 1832 there were about thirty phrenological societies, and several journals published in the interests of the system, which was supported by Macnish, Laycock, and Archbishop Whately. On the other hand, it was strongly controverted by Sir Charles Bell, Sir William Hamilton, Jeffrey, Brougham, Thomas Brown, and others; and their strictures and the progress of the scientific study of brain and mind in their various relations have to a large extent rendered it obsolete as a scheme. There is doubtless a large amount of truth in many of the generalisations. But anatomy and physiology have proved that the exterior surface of the brain is by no means an index to mental processes or characters; still less is such a guide furnished by the minute variations in the shape of the skull, which in a general way correspond to the exterior surface of the brain. Size of brain does not correspond directly to mental power or activity; nor is the superficial conformation the most important feature of the brain. Parts of the external surface are known to have functions other than those attributed by phrenologists; the frontal sinus of the skull is sometimes large enough to occupy the region allotted to four or five phrenological organs; and there are many osteological differences in the various bones of the skull which obviously have nothing to do with brain-functions or mental processes. An outline of what is known as to the localisation of brain-functions will be found at Brain, Vol. II. p. 391. For craniological characters, see Skull, Ethnology; and see also Physiognomy, Psychology.

Phrygia, a country in Asia Minor, the extent and boundaries of which varied very much at different periods of ancient history. In prehistoric ages it is believed to have comprised the greater part of the peninsula, but at the time of the Persian invasion it was limited to the districts known as Lesser Phrygia and Greater Phrygia—the former stretching along the shores of the Propontis and the Hellespont to Troas (afterwards part of Mysia), the latter occupying the centre of Asia Minor. Phrygia was in general a high and somewhat barren plateau, though its pastures supported immense flocks of sheep, noted for the fineness of their wool. The most fertile part was the valley of the Sangarius, but the most beautiful and populous district was the south-west, at the base of the Taurus, where the Mæander and other streams had their rise. The mountains and streams yielded gold; Phrygian marble was anciently celebrated, and the cultivation of the vine appears to have been extensively carried on. The Phrygians were apparently closely related to the Armenians, and have left their traces in almost all parts of Asia Minor. Later they were forced within narrower limits by the intrusion of Semitic and other aliens —Lydians, Carians, Thracians. In the 6th century Crœsus conquered all that was left of Phrygia, and in 549 he succumbed to the Persians. The influence of Phrygian religion on Greek mythology seems to have been great. Among their deities were Men or Manes, Cybele, and Athys; and Phrygia was a great centre of orgiastic worship and celebrations.

See W. M. Ramsay, *The Cities and Bishoprics of Phrygia* (1895–97). For the Phrygian Mode, see Harmony; for the Phrygian cap, see Bonnet.

Phryné, a celebrated courtesan, was the daughter of Epicles, born at Thespiæ in Bœotia, and originally earned a livelihood by gathering capers; but as the fame of her marvellous beauty spread she obtained numerous lovers, who lavished gifts on her so profusely that she became enormously rich. In proof of this the story goes that she offered to rebuild the walls of Thebes if the citizens would allow her to place this inscription on them: 'Alexander destroyed them; Phryne, the courtesan, rebuilt them.' The Thebans declined the proposal. Her enemies accused her of profaning the Eleusinian mysteries. Summoned before the tribunal of the Heliasts, she was defended by the rhetorician Hyperides, one of her lovers, who, perceiving that his eloquence failed to convince the judges, threw off her robe and showed her naked loveliness. She was immediately acquitted, and carried in triumph to the Temple of

Venus. The famous 'Venus Anadyomene' of Apelles is said to have been a portrait of Phryne. Praxiteles, also a lover of hers, employed her as a model for his 'Cnidian Venus.'

Phry'nichus. (1) an Athenian tragic poet, who gained his first dramatic prize in 511 B.C., twelve years before Æschylus, and his last in 476, when Themistocles was his *choragus*. He seems to have gone to the court of Hiero in Sicily, and to have died there. He introduced masks representing women, and to the light mimetic chorus of Thespis added the sublime music of the dithyrambic choruses. His most famous tragedies were the *Phœnissæ*, which is supposed to have inspired the *Persæ* of Æschylus, and another which had for its subject the capture of Miletus by the Persians. So overpowering was its effect that the audience burst into a passion of tears, fined the poet a thousand drachmæ for so harrowing a description of the sufferings of a kindred people, and forbade the piece ever again to be represented. His scanty fragments will be found in Nauck's *Tragicorum Græcorum fragmenta* (1856).

(2) A poet of the old Attic comedy, who was honoured by the abuse of his great contemporary Aristophanes (*Ran.* 14) for his low buffoonery. His fragments are collected in Meineke's *Fragmenta Comicorum Græcorum* (1839–57) and Koch's *Comicorum Atticorum fragmenta* (1880 *et seq.*).

(3) A Greek grammarian and sophist who flourished under Marcus Aurelius, and wrote a collection of select specimens of Attic usage intended for the benefit of his friend Cornelianus, secretary to the emperor. It consists of about four hundred short unconnected *dicta* on the orthography, signification, and use of particular words, and upon the rules of accidence, especially in verbs. The edition by Lobeck (1820) was followed by *The New Phrynichus*, by W. Gunion Rutherford (1881).

Phthalein. See DYEING, Vol. IV. p. 141.

Phthiotis, the south-east corner of Thessaly (q.v.), the home of Achilles.

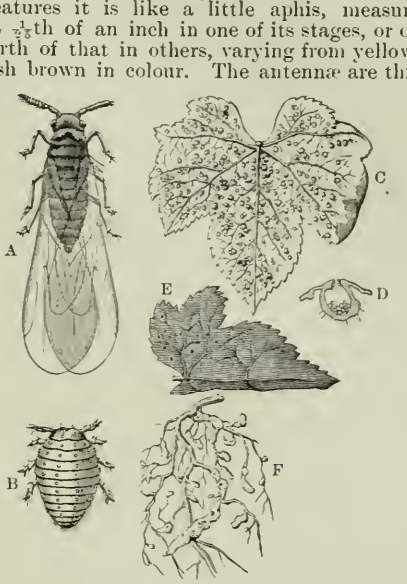
Phthisis. See CONSUMPTION.

Phylactery (Gr. *phylactērion*, 'an amulet'), the name given in the New Testament to small square boxes of parchment or black calf-skin, containing strips of parchment or vellum with certain texts of Scripture (Exod. xiii. 2–10, 11–17; Deut. vi. 4–9, 13–22) written on them. The phylacteries are worn on the left arm and on the head by all Jews (except Karaites) above thirteen years of age on week-day mornings during the time of prayer. This is done in accordance with their interpretation of Exod. xiii. 9–16. Some Russian and Polish Jews wear phylacteries all day; and they have at times been worn as amulets against demons. The writing of phylacteries is in the hands of privileged scribes (*Sofcrim*) only, and many and scrupulous are the ordinances which they have to follow in the execution of this task.

Phyllite, a schistose clay-rock, containing a variable proportion of quartz in grains, together with mica, usually chlorite, and sometimes many accessory minerals. The rock is more crystalline than clay-slate, and passes into mica-schist. The surfaces of the folia in phyllite are frequently finely wrinkled.

Phyllotaxis. See LEAF, Vol. VI. p. 548.

Phylloxe'ra (Gr. *phyllon*, 'a leaf,' and *xēros*, 'dry'), a genus of insects belonging to a family (Phylloxerinæ) nearly related to aphides and coccus insects, and included within the sub-order Homoptera in the order Hemiptera or Rhynchota. Two or three species occur in Europe, living like many related forms as parasites on plants. Most important is *P. vastatrix*, which ravages the vine, and has cost France alone a pecuniary loss far exceeding that of the Franco-German war. It seems to have been discovered in North America in 1854, and in all likelihood was carried thence to Europe, where it appeared about 1863. It now occurs in all vine-growing countries. In some of its features it is like a little aphis, measuring about $\frac{1}{75}$th of an inch in one of its stages, or only a fourth of that in others, varying from yellow to reddish brown in colour. The antennæ are thick,



Life-history of Phylloxe.a (from Leunis).

A, a winged female; B, a wingless female from the root; C, under surface of a vine-leaf, showing the wart-like galls; D, an enlarged section of one of the galls, showing the eggs within it; E, upper surface of a vine-leaf, showing the openings of the galls; F, some of the roots of the vine, showing the nodosities caused by the parasites.

with three joints; the legs are short and thick; there is no trace of the 'honey-tubes' characteristic of aphides; the winged forms, which are all parthenogenetic females, have four wings. As in the nearly related genus Chermes—a destructive parasite of conifers—the life-history is exceedingly complex.

Let us begin with the winged females, which in Europe appear from August to October. Each lays about four parthenogenetic ova on the under surface of the vine-leaves. These ova develop in late autumn into males and females—wingless and without the characteristic piercing and sucking mouth-organs—which migrate to the stem of the vine. There each female lays a single egg under the bark. This egg lies dormant throughout the winter, and develops in April or May into a wingless but voracious 'vine-louse.' This form may pass to the leaves, on which it lays parthenogenetic eggs, and forms galls; but in Europe it attacks the roots, and lays its eggs there. From these in about eight days young develop, which become mature females in about twenty days, and lay more eggs in the roots. Half a dozen or more of these parthenogenetic generations follow in rapid succession throughout the summer. The roots become knotted and deformed; the whole plant suffers, and, though it may survive for several seasons, eventually dies. In midsummer, among the subterranean forms, a generation is born whose members, after four, instead of the usual three, moultings associated with adolescence, become the larger winged females with which we began.

The destruction of this scourge of the grape-vine, without also injuring or destroying the plants, has hitherto proved impracticable, owing to the difficulty experienced in reaching its

subterranean haunts without disturbing or destroying the roots. Water, wherever it can be applied to the soil so as to saturate and keep it saturated for a time, has proved a safe and effectual destroyer, because the insect cannot live in a medium saturated with water for long. Chemical remedies, such as bisulphide of carbon, have been employed experimentally with success, but are found to be too expensive for general application on a large scale, even were the practical difficulty of conveying them into all depths of the soil and diffusing them in it surmountable. Several cases of attacks of phylloxera on vines in vineries in England have occurred since 1865. These attacks have been usually met by the process of 'stamping out.' The vines were destroyed by burning, the earth in which they grew was wholly removed, the walls of the vinery and the floor of the border on which the earth rested were thoroughly cleansed with salts or corrosives, and a fresh start was made with new earth and new vines; but while practicable to this limited extent, the remedy is obviously inapplicable to vineyards in districts collectively covering thousands of acres. In some of the French vineyards grafting the cultivated vines on certain of the native vines of America has been tried with some success. Although the insect seems to feed on the roots of these vines, the greater vigour of the American stocks appears to enable them to resist the injuries inflicted on them. Other chemicals—petroleum, tar, &c.—have been occasionally found helpful. Another method tried is the cherishing and multiplication of natural enemies of the phylloxera: these are numerous, and include *Hophlophora arctata*, *Polyxenus lagurus*, *Thrips*, *Aphidius*, &c. The extent of the disease in France is noted at FRANCE, Vol. IV. p. 774. The devastations were not serious in Austria and Portugal till 1872, in Germany till 1881; but France has suffered by far the most. Other species, including perhaps some varieties, occur on the oak, the hickory, the chestnut, and the willow.

See M. Cornu, *Études sur le Phylloxera vastatrix* (1879); J. Lichtenstein, *Histoire du Phylloxera* (1878); C. V. Riley, *Sixth Annual Report of the State Entomologist of Missouri* (1874); and L. Dreyfus, *Ueber Phylloxerinen* (1889).

Phylogeny (Gr. *phylon*, 'race,' and *genesis*), a biological term applied to the evolution or genealogical history of a race or tribe. It is used in contrast to 'ontogeny'—the development or life-history of an individual; witness Haeckel's 'biogenetic law:' 'Ontogeny is a recapitulation of Phylogeny.' See DARWINIAN THEORY, EMBRYOLOGY, EVOLUTION, HEREDITY.

Physalia. See PORTUGUESE MAN-OF-WAR.

Physalis. See WINTER CHERRY.

Physeter. See WHALE.

Physicians, THE ROYAL COLLEGE OF, was founded by the munificence of Thomas Linacre (q.v.), a physician and scholar. In 1518, through the influence of Cardinal Wolsey, he obtained from Henry VIII. letters-patent granting to John Chambre, himself, and Ferdinandus de Victoria, the acknowledged physicians to the king, together with Nicholas Halsewell, John Francis, Robert Yaxley, and all other men of the same faculty in London, to be incorporated as one body and perpetual community or college. They were permitted to hold assemblies, and to make statutes and ordinances for the government and correction of the College, and of all who exercised the same faculty in London and within 7 miles thereof, with an interdiction from practice to any individual unless previously licensed by the president and College. Linacre was the first president, and held the office till his death in 1524. The meetings of the College were held at his house in Knightrider Street, which he bequeathed to the College, and which until the year 1860 continued in the possession of that body. About the time of the accession of Charles I. the College, requiring more accommodation, took a house at the bottom of Amen Corner, which was subsequently purchased by Dr Baldwin Hamry, and in 1649 was given by him to his colleagues. This was the seat of the College till 1666, when it was destroyed by the great fire of London. A new College was then built in Warwick Lane, and opened in 1674 under the presidency of Harvey's friend, Sir George Ent; and here the meetings were held till 1825, when the present edifice in Pall Mall East was opened under the presidency of Sir Henry Halford.

The reason for forming the incorporation, as set forth in the original charter, is 'to check men who profess physic rather from avarice than in good faith, to the damage of credulous people;' and the king (following the example of other nations) founds 'a college of the learned men who practise physic in London and within 7 miles, in the hope that the ignorant and rash practisers be restrained or punished.' The charter further declares that 'no one shall exercise the faculty of physic in the said city, or within 7 miles, without the College license, under a penalty of £5;' that, in addition to the president, 'four censors be elected annually to have correction of physicians in London and 7 miles' circuit, and of their medicines, and to punish by fine and imprisonment;' and that 'the president and College be exempt from serving on juries.' Four years later, in 1522–23, an act was passed confirming the charter, and enacting that 'the six persons beforesaid named as principals and first-named of the said commonalty and fellowship shall choose to them two men of the said commonalty from henceforward to be called and cleped Elects, and that the same elects yearly choose one of them to be president of the said commonalty;' and further directing that, in case of a vacancy by death or otherwise, the surviving elects shall choose successors.

In 1540 an act was passed in which it was declared explicitly that 'surgery is a part of physic, and may be practised by any of the company or fellowship of physicians'—a doctrine which in later times has been totally repudiated by the collegiate body, who, until a few years ago, would not admit to their privileges a member of the Royal College of Surgeons unless he formally resigned his surgical diploma. Other acts were passed in 1553, 1814, and 1858; the last known as the 'Medical Act,' providing for the granting of a new charter to the College, which was obtained in 1862. Finally, in 1860, 'an Act to Amend the Medical Act' was passed, which repeals the provisions of the Act of 1522–23 as to the elects, and declares that the presidency shall in future be an annual office, open to the Fellows at large, who shall also be the electing body. As at present constituted, the College consists of Fellows, Members, Licentiates, and Extra-Licentiates (in 1891, 298 Fellows 466 Members, 4037 Licentiates, and 30 Extra-Licentiates). The *Fellows* are elected from members of at least four years' standing, who have distinguished themselves in the practice of medicine, or in the pursuit of medical or general science or literature. The government of the College is vested in the president and Fellows only. The present *Members* consist of persons who had been admitted, before 16th February 1859, licentiates of the College; or extra-licentiates who have complied with certain conditions; and of persons who have attained the age of twenty-five years, and who, with rare exceptions, must be

graduates in medicine of a recognised university or licentiates of the College, who do not dispense or supply medicine, and who, after being duly proposed, have satisfied the College 'touching their knowledge of medical and general science and literature.' No candidate is admissible if engaged in trade or connected with a druggist's business, or who even practises medicine in partnership with another practitioner, so long as the partnership lasts, or who refuses to publish, when required, the nature and composition of any remedy he makes use of. The *members* are alone eligible for the Fellowship. They have the use of the library and museum and the privilege of admission to all lectures; but they do not take any share in the government or attend or vote at meetings. The examiners for the membership are the president and censors. The *Licentiates* are not members of the corporation; they have access to the museum, lectures, and reading-room, but are not allowed to take books away from the library; they may compound and dispense medicines for *patients under their own care;* and in their qualifications very much resemble those who have diplomas both from the College of Surgeons and the Apothecaries' Hall. They must be twenty-one years of age, and must have been engaged in professional studies for four years before being admitted to examination. The fee for admission as a Fellow is thirty guineas, exclusive of stamp-duty; the Member's fee is also thirty guineas, and the Licentiate's fifteen guineas.

The following bylaws of the College should be generally known: (1) No Fellow of the College is entitled to sue for professional aid rendered by him. This bylaw does not extend to Members. (2) No Fellow, Member, or Licentiate of the College is entitled to assume the title of Doctor of Medicine unless he be a graduate in medicine of a university. (3) No Fellow or Member of the College shall officiously, or under colour of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner.

The Royal College of Physicians of Edinburgh had its rise in 1617, in an attempt to incorporate the practitioners of medicine, and raise the standard of the profession. King James I. of England looked favourably on the proposal, and granted an order for its establishment. King Charles I. also gave the matter his attention and referred it to the Privy-council, and Cromwell in like manner issued a patent in its favour; all these attempts, however, were frustrated by the religious and political dissensions of the times, and it was not until 1681 that the body became incorporated under a charter from Charles II. A new charter with many important provisions was issued in 1861. To the Physicians belongs the honour of having suggested in 1725 the plan of an infirmary in Edinburgh for the sick poor, which has developed into the present magnificent institution. From the first they undertook its medical charge gratuitously. The Royal Edinburgh Asylum for the Insane at Morningside was also first suggested by them in 1791. The College, which in 1890 had over 190 Fellows, possesses a library of upwards of 30,000 volumes, a valuable and interesting museum of materia medica, and a splendidly equipped laboratory for the purpose of aiding the prosecution of scientific research. An important arrangement was made in 1859 between this college and the Royal College of Surgeons (q.v.) of Edinburgh, making it competent for the two to combine, in order, by a joint examination, to give a double qualification, embracing medicine and surgery. In 1884 a further consolidation of the Scottish medical corporations took place, by the institution of a triple qualification, granted by the Edinburgh colleges and the Faculty of Physicians and Surgeons of Glasgow conjointly.

Physic Nut (*Curcas*), a genus of plants of the natural order Euphorbiaceæ, whose species are tropical shrubs or trees, having alternate, stalked, angled or lobed leaves, and corymbs of flowers on long stalks. The Common Physic Nut of the East Indies (*C. purgans*), now also common in the West Indies and other warm parts of the world, is a small tree or bush, with a milky juice. It is used for fences in many tropical countries, and serves the purpose well, being much branched and of rapid growth. The seeds are not unpleasant to the taste, but abound in a very acrid fixed oil, which makes them powerfully emetic and purgative, or in large doses poisonous. The expressed oil, commonly called *Jatropha-oil*, is used in medicine like croton-oil, although less powerful; it is also used in lamps. Other species are *C. multifidus* and *C. lobatus*.

Physics, or Physical Science (Gr. *physikos*, 'natural'), comprehends in its widest sense all that is classed under the various branches of mixed or applied mathematics, natural philosophy, chemistry, and natural history, which branches include the whole of our knowledge regarding the material universe. In its narrower sense it is equivalent to Natural Philosophy (q.v.), which until of late years was the term more commonly used in Great Britain, and denotes all knowledge of the properties of bodies as bodies, or the science of phenomena unaccompanied by essential change in the objects; while chemistry is concerned with the composition of bodies, and the phenomena accompanied by essential change in the objects, and natural history, in its widest sense, includes all the phenomena of the animal, vegetable, and mineral world. The use (now obsolescent) of the term *Physic* for a branch of this last—viz. the science of medicine—is not peculiar to the English language. The Old French usage recognised *physique* in the sense of medicine; while almost all languages have used some form of the word *physician* for a practitioner of the art. See Science.

Physiocratic School, a school of political economists in France headed by Quesnay and Gournay, who, in opposition to the Mercantile System (q.v.), regarded agriculture as the great source of national well-being, and sought to regulate legislation accordingly. Turgot (q.v.) was the most conspicuous member. See Political Economy.

Physiognomy (from a Latin shortened form of the Gr. *physiognomōnia*), the art of judging of the character from the external appearance, especially from the countenance. The art is founded upon the belief, which has long and generally prevailed, that there is an intimate connection between the features and expression of the face and the qualities and habits of the mind; and every man is conscious of instinctively drawing conclusions in this way for himself with more or less confidence, and of acting upon them to a certain extent in the affairs of life. Yet the attempt to reach this conclusion by the application of certain rules, and thus to raise the art of reading the human countenance to the dignity of a science, although often made, has never yet been very successful. Comparisons were instituted for this purpose between the physiognomies of human beings and of species of animals noted for the possession of peculiar qualities, as the wolf, the fox, &c. The subject was prosecuted by Della Porta (died 1615), Campanella, Cardan, Ingegneri, and especially by Lavater (q.v.). Darwin's *Expression of the Emotions in Man and Animals* (1873) is regarded as the first attempt to base a rational physiognomic system on a basis of modern scientific

research; Mantegazza, in *Physiognomy and Expression* (Contemp. Sc. Series, 1890), claims to have begun where Darwin left off. Piderit, in *Mimik und Physiognomik* (2d ed. 1886), proceeds on the obvious fact that the most valuable data are not to be derived from the bony framework of the countenance, but in the mobile parts which express emotion; features which constantly express the same emotion come to be stamped with permanent physiognomic characters. Pathological physiognomy is a systematised effort to diagnose mental or bodily ailments by examination of the varying facial expression. Another practical application of physiognomic study is found in what has been called *Criminology;* see Havelock Ellis, *The Criminal* (Contemp. Sc. Series, 1891).

Physiography, a term formerly used of a branch of mineralogy, was adopted by Professor Huxley as a convenient name for an exposition of the principles that underlie physical geography, and including the elements of physical science. Physiography is thus understood to involve a compendious discussion of gravitation, heat, the composition of the crust of the earth, the movements of the sea, the phenomena of the atmosphere, and many cognate subjects, treated in this work under separate heads. See GEOGRAPHY.

Physiologus. See BESTIARY.

Physiology (Gr. *physis* and *logos*, 'discourse upon nature') is the science which treats of the behaviour of living beings, and of the functions of their parts. It is thus the sister-science to Morphology (q.v.), in which the outer form of living creatures and the structure and arrangement of their parts are considered. Both are included under the more general term Biology (q.v.). A peculiar use of the term *physis* is due to Hippocrates, who applied it to a spiritual entity which he supposed to be everywhere present, and to keep the processes of the body in order. This use of the word is still kept alive in oft-repeated phrases, as when in speaking of a sick person it is recommended that the cure be left to nature. There is an Animal Physiology, of which this article will mainly treat, and a Vegetable Physiology (q.v.); also a Comparative Physiology, which, however, is still very imperfect, for the details of the life-processes have been investigated in not more than a dozen animals. Indeed, comparative physiology consists chiefly of a series of inferences as to function from comparative morphology, and these must be often erroneous. There is a still wider science, which might be called Universal Physiology. For as all the organs of the body are mutually related, so that if one be deranged all the others will be more or less affected, so are there close relationships between the various creatures of the globe. Thus, to quote Semper, *Animal Life* (1881): 'If the American prairies were to cease to produce grass, the first result would be the utter extinction of the now numerous herds of buffaloes, and on their existence depends that of the surviving remnant of the ancient Indian population of America. If the various insectivorous birds of North America were exterminated, within a very few years beyond a doubt all the produce of the rich agricultural districts of that continent would be destroyed. If we change the mode of life of any single animal, the change will instantly have an influence on all the other animals whose healthy existence was in any way dependent on its normal function before it was altered.' The most obvious relation of this sort is that which exists between plants and animals; similar ones hold good for human beings in their relationship to other living things, and to each other. Thus we see in Political Economy, the science which treats of the laws of human activities, a department of the science of physiology. A still wider significance might be given to the science; for in view of the fact that the intimate relations between chemical, physical, and living processes are becoming daily more evident, it would be quite consistent that morphology should deal not only with the forms of plants and animals, but also with those which the dust assumes in the crystal, pyramid, and star, while physiology would treat of the forces and chemical processes concerned.

Knowledge of the bodily functions has been gained in three ways: (1) by observing the normal states of living things; (2) by experiments upon these; (3) by studying the processes of disease. No science can advance rapidly or with certainty without experiment, and most of our precise knowledge of physiology has been gained in this way, from the time when Galen proved that the arteries during life contain blood, or when Harvey demonstrated the circulation of that blood. As an example of how we may learn from disease, we may note the discovery that the spleen produces white blood-corpuscles, following from the observation that in morbid enlargement of that organ the blood contains an increased number of these cells.

The functions of the body consist of (1) Movement, (2) Nutrition, (3) the activities associated with the Nervous System, (4) Growth and Reproduction—the latter being considered as continued growth. Movement is performed by the contraction of muscles, definitely arranged, especially with relation to the skeleton or supporting structure. Nutrition is a general term including all those processes concerned in the supply of matter and energy to the body, and the removal of waste matter. It may be considered under three headings: (1) the introduction of food into the body and its carriage to the tissues; (2) the changes of this matter within the tissues; (3) the removal of waste matters from the tissues and from the body—Excretion (q.v.). The first includes (*a*) the eating and drinking of solid and liquid food, and the intaking of oxygen, a part of Respiration (q.v.); (*b*) the Digestion (q.v.) of the food; (*c*) its absorption into the Blood (q.v.); (*d*) the circulation of the blood and its associate the Lymph (q.v.), by means of which the tissues are bathed in a stream of food, and the waste matters removed from them. The nervous system is the co-ordinator of all the processes of the body; it consists of the Brain, Spinal cord, Sympathetic system, and the associated Nerves and smaller Ganglia; in close connection with it are the sense-organs, the eyes, ears, nose, tongue, and general nerves of touch and temperature; the brain is the seat, or at all events the chief seat, of consciousness, and the 'organ' of thought and other mental processes. The functions of the body are dealt with in separate articles; here we shall give a short account of their relations to each other.

Let us first consider the life of the simplest animals. Almost invisible to unaided sight, flourishing in the stagnant water of ponds, without separate organs, they are little more than tiny masses of jelly-like Protoplasm (q.v.). Their life seems to consist in movement, nutrition, growth, and reproduction; possibly they possess the elements of consciousness. For movement a source of energy is required; this is found in their food—minute organisms, and organic particles dissolved in the water in which they live. These consist of substances of high potential energy. They are either plants which are able to utilise the energy of the sun for their growth, or remains of plants or animals which have fed upon plants (see VEGETABLE PHYSIOLOGY). Thus we see in animal

protoplasm a machine for the transformation of potential energy into energy of motion. This machinery is constantly breaking down and being repaired, the protoplasmic matter is continually being replaced by new matter similarly combined. But, as the protoplasm is extremely complex, the simpler substances of the food have to be combined and recombined in a series of stuffs of increasing complexity until the complex living matter itself is formed. These combinations are supposed to be due to a ferment-like power of the protoplasm. This power it is which makes growth possible — i.e. the actual increase in amount of protoplasm. The growth of a crystal out of its solution is probably a process not utterly unlike, though much simpler. Growth of a crystal may seemingly be endless, but growth of a cell never proceeds beyond a certain point, when the process known as Cell-division occurs. The mass of protoplasm divides into two halves, and each half goes on to live as before. The necessity for cell-division arises partly from the conditions of the food-supply. Food is absorbed through the surface of the cell, but with growth the mass to be fed increases faster than surface; therefore starvation must occur at a certain stage of growth unless the cell divides. The higher animals are built up of numberless cells which have all arisen, by division, from a single cell, the ovum; but instead of becoming separated they have all kept together, joined probably by strands of protoplasm. The cells are massed into tissues and the tissues into organs, the organs having special functions. This difference in the behaviour of the cells of different parts of the body is known as Division of Labour (q.v.). We can form some idea of its origin. Imagine a cell to divide many times, but the daughter-cells to remain loosely joined together; the outer and inner cells would live under different conditions and would assume different functions. The whole story of the evolution of life, both in the origin of individual forms and in the growth of nations, is simply the process of the division and organisation of labour. For just as an organism is a collection of cells, each having its own life, yet all bound together for mutual service, so is a nation a collection of individual men and women. And as the perfection of an animal is measured by the completeness of the division of labour among its cells, so is the civilisation of a nation measured by the harmony of organisation of its labour. Further, just as there have been many species of animals which have appeared, lived for a time, and then given place to higher species, so there have been civilisations which have flourished for a time and then died away. Any fairly complex civilisation will serve as a type of the division of labour in the body of one of the higher animals. First there are the persons concerned in the getting of food, like the limbs and mouth of an animal. Then the food is prepared for use by other labourers; such are the digestive organs of the animal. The food has to be distributed to all members of the community by merchants and carriers; the blood and the blood-vessels perform this function. The whole community has to be warned of dangers, directed and governed, and made to act harmoniously by the statesmen of a nation; the same things are done by the sense-organs, brain, and nervous system of an animal.

We have already noted that the source of all the energy of an animal lies in its food. We know that this is either burned as it were within the tissues, used as fuel for the protoplasmic machinery, or used to keep that machinery in repair; in either case the food-stuffs have to be prepared before they can be used. Such preparation is called *digestion*, which consists in making the solid food-stuffs soluble. The digested food is absorbed into the blood, and all of it, except the fat, is carried direct to the liver. This organ, amongst other functions, regulates the composition of the blood; thus, it stores the sugar in its cells, and gives it out as the other tissues require. Muscular tissue is the great consumer of sugar, which is to the cells what coal is to the steam-engine. But there is another and most important food-stuff that requires no digestion. This is oxygen, which is needed by the protoplasm for its life, and also for the burning of fuel within the living machinery to get heat and energy of motion. The oxygen is held in the Blood (q.v.) by means of a special substance which greedily absorbs it from the air in the lungs, and yet gives it up readily to the protoplasm of the tissues. The blood as is well known circulates round and round the body, pumped by the heart. It is a stream of food material by which each cell of the tissues is fed. For each cell is close to a capillary, which is a very thin walled blood-vessel, through which the fluid food oozes, and thus bathes the tissues. The matter which has thus passed out of the blood-vessels is collected into another system of vessels, the lymphatics, and eventually emptied into one of the great veins. The lymph stream is also the drain into which is thrown by each cell the waste products of its activity. The carbonic acid that is formed in the tissues is carried away by the blood, and escapes out of the system from the lungs. Some of the useless water is also got rid of in the same way, and some more of it is sweated out by the glands in the skin; the rest is filtered out of the blood by the kidneys. There are many other waste matters besides carbonic acid and water. These are to a large extent prepared for excretion in the liver, and to some extent actually taken out of the blood by that organ, being poured into the intestine, mixed with other matters, dissolved in a fluid called Bile (q.v.). They are all taken out of the blood by the kidneys, and cast out of the body along with the water filtered out by the same organs, as urine.

This finishes our sketch of the labours of the inferior members of the cell community. The more skilled workmen are the cells of the sense-organs and the nervous system; these are described in other articles. As has been noted, their function is to inform the community of what is going on in the outside world, and to keep in harmony all the diverse labours of the various organs.

The function of Reproduction is treated in that article. There remains only the duration of life to consider and the fact of death. The general theory of the length of life is set forth in the article on longevity. The usual view of death is that it is inherent in living matter; that there is some cause which renders the cells of the body, after a certain period of life, and after a certain number of divisions, less and less able to nourish themselves, to continue dividing, and to keep the body in repair. Recently it has been suggested by Weismann that death has been evolved by natural selection as a preventive against the continuance in life of maimed individuals (for no one can escape slight injuries) that would be only a burden to the species.

For Comparative Physiology, see the articles on the various functions and groups of animals.

The History of Physiology, in its limited sense as the study of the life-processes of individual organisms, is the history of an ever-deepening analysis. The science begins with the study of the general habits of animals; the life-processes are then resolved into the functions of the various organs, the organs are analysed into their component tissues, the tissues into cells (see CELL),

and lastly, the essential constituent of the cell is discovered in Protoplasm (q.v.). The last three stages, beginning with the analysis of organs into tissues, have been developed within the last hundred years. The history looked at from this point of view is enlarged upon in the article BIOLOGY; here we shall give a history of a more detailed nature. Preyer divides it into five periods—(1) the speculative period; (2) that associated with the name of Aristotle; (3) headed by Galen, (4) by Harvey and Haller, and (5) by Müller. The first period opens with the beginning of medical science in India, China, and Egypt. The Jews were acquainted with many laws of practical hygiene and dietetics. Then came the philosophers of Greece. Matter was supposed to consist of four elements, fire, air, earth, and water. The essence of life was referred first to one and then to another of these elements by various philosophers: by Thales to water, by Anaximenes to the air, by Xenophon to the earth, by Pythagoras to fire or heat. Hippocrates, the father of medicine, about 450 B.C., was the first to proceed in a purely rational spirit. Observing carefully the facts of disease, he strove to found the art of medicine upon the results of experience. He attributed diseases to natural causes, and not to special visitations of the gods; and as already noted, he postulated a spiritual essence universally diffused; this he called Nature, Physis, and to this he ascribed the maintenance of things in their normal state, and their restoration if disturbed. The second period is headed by Aristotle, the father of natural history, about 350 B.C. He dissected many animals, and attempted to discover the uses of the various parts. It is difficult to estimate correctly the exact value of Aristotle's work in physiology; it must be measured more by the methods of research which he initiated than by the actual results achieved. Thus, to give an example of his ideas on the subject, the heart he imagined as the seat of the 'rational soul;' the nerves he supposed to arise in the heart; of their function he was ignorant. What is perhaps more surprising is that he described the brain as an inert viscus, cold and bloodless, whose only function was to cool the heart, and not comparable in importance to the other organs of the body. Erasistratus, the grandson of Aristotle, about 300 B.C., was perhaps the first to carefully dissect the human brain. He traced the connection of nerves with it, and even noticed that the complexity of the convolutions of the gray matter was greatest in man, and that they were to some extent a measure of the intelligence. The next 400 years were barren of any useful advance; the practice of medicine reached perhaps its lowest point. The literature is occupied with discussions as to the 'animal and vital spirits,' terms used before Aristotle to express the powers of living things. The animal spirits were those that ruled over those actions of living things that were supposed to be quite different from anything that takes place in things not living, while the vital spirits were those that were concerned in those processes going on in the body which were the result of purely chemical and physical laws. We no longer discuss whether the vital spirits live in the heart and the animal in the brain, but we have not yet settled the exact relationship between the processes of the living world and those of inorganic matter.

About 150 A.D. Galen, a Roman, revived the sounder method of experimental inquiry; he is the leader of the third period. He perceived that mere dissection of dead animals gives no infallible information as to the functions of the living, and accordingly performed many experiments upon living animals. He proved that during life the arteries contain blood and not air, as was thought to be the case up to that time, by simply opening a vessel of a living animal. He also directed much of his study to the brain and nervous system. He was the first to state definitely that the brain, spinal cord, and nerves are the organs of sensation, intelligence, and the originators and guides of properly ordered voluntary movements; and he finally refuted the doctrine of Aristotle by showing that the brain was hot and not cold, and by arguing also that if it were a mere cooler of the blood it need not be elaborately organised. He pointed out that the brain was of the same substance as the nerves, but softer, 'as it should necessarily be, inasmuch as it receives all the sensations, perceives all the imaginations, and then has to comprehend all the objects of the understanding, for what is soft is more easily changed that what is hard.' He discovered also that the nerves of sensation and of motion are distinct, and thus explained the double supply of nerves to the tongue and eyes. For centuries Galen exercised an undisputed sway over the practitioners of medicine and the students of allied philosophy.

Some centuries afterwards the so-called Arabian physiology arose. Avicenna, about the year 1000, was its chief exponent. Once more, however, the discussions were about the nature and residence of the animal and vital spirits. Albertus Magnus, in the 13th century, and Paracelsus, in the 15th century, are representatives of mediæval mysticism. About the same time, during the revival of learning, the mathematicians and chemists were busy seeking to explain bodily functions in terms of mechanical, chemical, and physical laws. In the 16th century Villanovanus described correctly the action of the lungs as purifiers of the venous blood. The study of human anatomy was revived by Vesalius in Italy, and continued by Fabricius; and in the beginning of the 17th century Harvey, who had studied in Italy, made perhaps the most important of all physiological discoveries, that of the circulation of the blood.

This discovery inaugurates the fourth period of the history of physiological research; by it a sound foundation for the whole science was laid, and the development of surgery and medicine made possible. Then, after the invention of the microscope, came many active investigators; among them may be mentioned Malpighi and Leeuwenhoek; and thus the foundations of Histology (q.v.) were laid. Haller, near the end of the 18th century, gave to physiology the form that it now possesses. He attempted to discard from the science all statements of a vague and mystical character, he added many minor discoveries to the store of facts, and ranged the whole in a logical sequence.

The great leader of the fifth period, Johannes Müller, during the first half of the 19th century, gave to the science a greater width. He connected as one philosophy the truths of chemical physics, comparative anatomy and physiology, and embryology. Embryology was founded as a science by Von Baer. Cuvier developed comparative anatomy, and thus gave a foundation to the study of comparative physiology. Lamarck enunciated the laws of evolution. Berzelius placed animal chemistry upon a sound basis. The discovery of the mechanical equivalent of heat by Joule, the enunciation of the cell-theory by Schleiden and Schwann, and the discovery of protoplasm as the essential constituent of the cells by Von Mohl and Du Jardin are the great steps which have placed us in our present position. The discovery of reflex action by Marshall Hall, of inhibitory nerve action by Weber, and of the glycogenic function of the liver by Claude Bernard mark important advances. With the work of this last mentioned the physiology of Protoplasm (q.v.) begins. The conception of evolution, rendered

acceptable by Darwin's work, is the great harmoniser of all science.

This history of physiology may be shortly summarised as follows. Even to early inquirers it was obvious that many of the life-processes of animals are the result of the action of a set of machines, which, as we know, were supposed to be kept in action by the 'vital spirits.' These machines were called organs, and the work performed was spoken of as their functions. The whole body was conceived of as made up of various organs, and the labours of physiologists were directed towards discovering their functions, a work which to this day is incomplete. This may be called the first phase of physiological philosophy; it lasted until the promulgation of the cell-theory and the rapidly following discovery of protoplasm. The idea of protoplasm is to natural science of nearly as much importance as the doctrines of the conservation of matter and energy are in chemistry and physics. The chief labours of physiologists for a very long time will be directed towards attaining exact conceptions of the nature of this protoplasm in terms of chemistry and physics. The old question of animal and vital spirits is still unsolved; we are not able to say whether there is any abrupt distinction between ordinary matter and that which is called living matter, and which forms 'the physical basis of life.' Is it merely that living matter is more complex and unstable than ordinary matter, and therefore far more sensitive to external impulses in the form of ethereal and molecular vibrations; or is there some special vital force at work? If we fully understand the first theory we shall probably believe that there is no such vital force. At any rate the surest path to its discovery lies in determining how far the *objective* phenomena of life are explicable in terms of ordinary chemical and physical laws. When we find any activity of living matter which we can be certain cannot be so explained, then, and not till then, may we postulate a vital force. Supposing such a discovery ever to be made, it is necessary to observe that it will merely widen our chemistry and physics. The discussion of the subjective consciousness of life is an entirely separate one. Ordinary philosophy postulates two entities, matter and spirit; Materialism holds that matter when it reaches a certain stage of complexity becomes conscious; Monism, which is becoming the fashionable scientific creed, teaches that matter in motion and consciousness are the two sides—one seen from without, the other felt from within—of a single entity.

We may fitly close by quoting Foster's statement of the present problems of physiology. He speaks of them as threefold. '(1) On the one hand, we have to search the laws according to which the complex unstable food is transmuted into the still more complex and still more unstable living flesh, and the laws according to which the living substance breaks down into the simple, stable, waste products, void, or nearly void, of energy. (2) On the other hand, we have to determine the laws according to which the vibrations of the nervous substance originate from extrinsic and intrinsic causes, the laws according to which these vibrations pass to and fro in the body, acting and reacting upon each other, and the laws according to which they finally break up and are lost, either in those larger swings of muscular contraction or in some other way. (3) And lastly, we have to attack the abstruser problems of how these neural vibrations, often mysteriously attended with changes of consciousness, as well as the less subtle vibrations of the contracting muscles, are wrought out of the explosive chemical decompositions of the nervous and muscular substances—i.e. how the energy of chemical action is transmuted into, and serves as the supply of that vital energy which appears as movement, feeling, thought.'

Phytelephas. See IVORY (VEGETABLE).

Piacenza, a city of Northern Italy, on the right bank of the Po, a little below its confluence with the Trebbia, by rail 43 miles SE. of Milan and 35 NW. of Parma. Situated at the end of the Via Æmilia and at the last convenient crossing-place eastwards on the Po, it has always been an important city, both strategically and commercially, since its foundation (as *Placentia*) by the Romans in 219 B.C. It is defended with bastioned walls and an outer ring of forts. Its streets are broad and regular, but many of them unfrequented and grass-grown. The cathedral, in the Lombard-Romanesque style (1122–1233), has an immense crypt, a campanile 223 feet high, and paintings by L. Carracci, Guercino, and others. The church of Sant' Antonino, the original cathedral, was founded in 324, but has been several times rebuilt. The church of Santa Maria della Campagna is adorned with fine frescoes by Pordenone; and it was for San Sisto that Raphael painted the celebrated Sistine Madonna, sold in 1754 by the monks to Frederick Augustus of Saxony. Among the other buildings are the Palazzo Farnese (1558), once a sumptuous edifice, but since 1800 in use as barracks; the communal palace (1281), its lower story built of marble and the upper of brick; the palace of justice, and others. A couple of miles to the east of the city is the theological seminary founded by Cardinal Alberoni. The municipal library contains 120,000 volumes. The principal square is adorned with colossal bronze equestrian statues of Alessandro and Ranuccio Farnese. Manufactures of silks, cottons, pottery, hats, &c. are carried on. The more notable facts in the history of Piacenza have been its capture by the Gauls in 200 and by Totila in 546, the meeting here of two church councils in 1095 and 1132, its active zeal as a member of the Lombard League in the 12th century, the sacking of it by Francesco Sforza in 1447, and its union with Parma (q.v.). Pop. (1897) 35,500.—The *province* has an area of 950 square miles and a pop. of 230,000.

Pia Mater. See BRAIN.

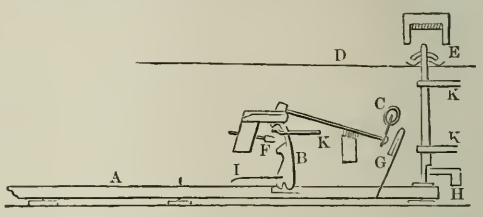
Piana Dei Greci, a town of Sicily, 10 miles SW. of Palermo. It was the chief Albanian colony in Sicily in the 15th century.

Pianoforte (Ital. *piano*, 'soft,' and *forte*, 'loud'), a stringed musical instrument, played by keys, developed out of the clavichord and Harpsichord (q.v.), from which the pianoforte differs principally in the introduction of hammers, to put the strings in vibration, connected with the keys by a mechanism that enables the player to modify at will the intensity of the sounds; whence the name of the instrument. The invention of the pianoforte must be accredited to Bartolomeo Cristofali, a native of Padua, who produced his instrument in 1714. Other claimants to the honour are a German organist of the name of Schröter, and Marius, a French harpsi-

chord maker. The first pianoforte seen in England was made at Rome by Father Wood, an English monk there. In Germany the invention met with more rapid encouragement and development than in Italy. The Silbermanns in Strasburg and Stein of Augsburg improved the discoveries of their countryman Schröter, and many Germans are found to maintain that the pianoforte is an independent invention indigenous to the Fatherland. In England the manufacture of the instrument was at first chiefly in the hands of foreigners, principally Italians. Italian pianoforte-makers opened many shops, but the English makers ultimately rivalled and surpassed them. The English pianoforte has been brought to its present state of perfection by Broadwood, Collard, Brinsmead, and others. Erard made many improvements in France; Germany has long been famous for its pianos, including those of Bechstein; and the American pianos of Steinway and Chickering are well known.

The compass of the early pianoforte was, like that of the harpsichord, four to five octaves, and has gradually increased to seven octaves, or occasionally more. The most natural of the various forms which the instrument assumes is that of the grand pianoforte, derived from the harpsichord, with the strings placed horizontally, and parallel to the keys. The strings are stretched across a compound frame of wood and metal, composed of bars, rods, and strengtheners of various kinds—appliances necessary to resist the enormous tension. This framework includes a wooden sound-board. The mechanism by which hammers are connected with the keys is called the *action* of the instrument. In the earliest pianofortes the hammer was raised from below by a button attached to an upright wire fixed on the back-end of the key. The impulse given to the hammer caused it to strike the string, after which it immediately fell back on the button, leaving the string free to vibrate. This was called the *single action*. As the hammer, when resting on the button with the key pressed down, was thus necessarily at a little distance from the string, the effectual working of this action required that a certain impetus should be communicated to the hammer to enable it to touch the string. Hence it was impossible to play very piano, and it was found that, if the hammer was adjusted so as to be too close to the string when resting on the button, it was apt not to leave the string till after the blow had been given, thereby deadening the sound. This defect was remedied by a jointed upright piece called the *hopper*, attached to the back-end of the key, in place of the wire and button. When the key was pressed down the hopper, engaging in a notch in the lower side of the hammer, lifted it so close to the hammer that the lightest possible pressure caused it to strike; and at this moment, when the key was still pressed down, the jointed part of the hopper, coming in contact with a fixed button as it rose, escaped from the notch, and let the hammer fall clear away from the string. To prevent the hammer from rebounding on the string a projection called the *check* was fixed on the end of the key, which caught the edge of the hammer as it fell, and held it firmly enough to prevent it from rising. A necessary part of the action is the *damper*, which limits the duration of each particular note, so as to cause it to cease to sound as soon as the pressure is removed from the key. It consists of a piece of leather resting on the top of the string and connected with the back-part of the key by a vertical wire. When any key is pressed down its damper is raised off the string, so as to allow the sound produced to be clear and open; but immediately on the finger being lifted off the key the damper-wire falls, and the damper again presses on the string, muffling and stopping the vibration. The pianoforte possesses two pedals, the loud and the soft. By the former the dampers are raised, the result of which is to prolong the sound of the notes and cause them to run into one another. The employment of this pedal is designated by the word *ped.* written below the treble staff, while an asterisk is used to denote its cessation. The soft pedal, on the contrary, diminishes the sound, by removing a string from the impact of each of the hammers. Its employment in the music is denoted by the words *una corda*. One further frequent and important addition to the action may be alluded to. In the mechanism above described the key must rise to its position of rest before the hopper will again engage in the notch of the hammer for another stroke; hence a note cannot be repeated until time has been allowed for the full rise of the key. The *repetition action* is a contrivance, varying in different instruments, for getting rid of this defect by holding up the hammer at a certain height while the key is returning.

Great difference of detail exists in the actions of different makers. Some are more complicated than others; but in all are to be found the same essential parts, only modified in shape and arrangement. The subjoined figure represents one of the simplest grand pianoforte actions now in use. A is the



key; B, the lever which raises the hammer; C, the hammer; D, the string; and E, the damper: F is the button which catches the lever after it has struck the hammer; G, the check; H, the damper pedal-lifter; I, the spring; and K, K, K are rails and sockets. Formerly the strings of the pianoforte were all of thin wire; now the bass-strings are very thick, and coated with a fine coil of copper-wire; and the thickness, strength, and tension of the strings all diminish from the lower to the upper notes. A grand pianoforte has three strings to each of the upper and middle notes, and now, generally, only two to the lower notes, and one to the lowest octave. When the soft pedal is pressed down the hammers are shifted sideways, so as to strike only two strings instead of three, or one string instead of two.

Besides the full or concert grand, there is the semi-grand or square piano with curtailed keyboard, now superseded by the cottage piano, of which the upright grand is merely a larger form. In the cottage piano the strings run vertically from top to bottom of the instrument; and the difference in form necessitates alterations in the details of the action, but the general principle is the same. The pianette, a small form of the cottage, has also come into great favour. The pianoforte has attained a widespread popularity, owing chiefly to the fact that it can render harmony; though the violin is proving a serious rival to it in domestic circles. In England the manufacturers who have for some time past enjoyed the highest repute are Messrs Broadwood, Brinsmead, and Kirkman. Messrs Brinsmead have lately introduced a patent pianoforte called the *Sostenente*, in which, by a number of hammers playing consecutively on a string, and so closely as to cause no interruption in the sound, any note may be sustained (whence the name *sostenente*) for an indefinite length of time,

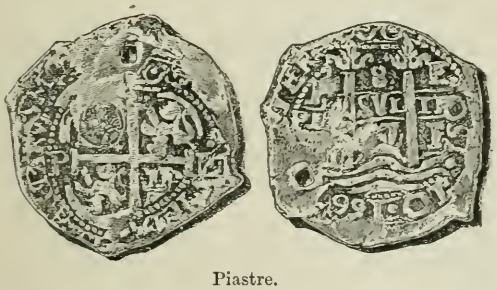
and the same solemn and majestic effect may be produced upon the pianoforte which has heretofore been confined exclusively to the organ. The latest development to which the pianoforte has been carried is that introduced by an Austrian of the name of Janko. A great number of his pianos are now being made. Recognising the complete change which has passed over pianoforte music since the days when Mozart and Haydn wrote and, so to speak, created the literature of the instrument, Herr Janko has endeavoured to adapt the piano to the long stretches, chords, and difficult arpeggios which are the characteristics of modern playing, and were utterly unknown, or rather unemployed, in the days of the classical writers. Accordingly, he constructs his pianos with six keyboards, which rise in tiers above one another in the manner of an organ. The notes are so grasped that tenths and twelfths can be easily spanned by reaching a finger to a keyboard above or below that on which the hand is travelling; and, with a sweep of the wrist, which would scarcely cover more than two octaves on the old keyboard, an arpeggio can be executed through the whole compass of the piano's notes. The objections to Herr Janko's improvement come mainly not from the public but from the music publishers; for, while to a beginner on the instrument it is immaterial what system of fingering be adopted, publishers are naturally jealous of a new pianoforte which would render useless and compel complete remodelling not only of all the fingering, but perhaps of the staff.

Music for the pianoforte is written in two staves, and with the treble and bass clefs. Many of the most eminent musicians have devoted themselves to composing for the pianoforte, and some composers of note, as Hummel, Chopin, Thalberg, and Heller, have almost entirely confined themselves to that instrument. Amongst the greatest modern pianists have been Madame Schumann, Liszt, and Rubinstein. See Rimbault, *The Pianoforte* (1860); Grove's *Dictionary of Music and Musicians;* and the histories of music and of musical instruments (such as Hopkins's *Musical Instruments*, 1887).

Piarists, or 'Fathers of the Pious Schools,' a religious congregation for the education of the poor, founded at Rome in 1617 by a Spanish priest, Joseph of Calasanza, and confirmed in 1621 by Gregory XVI. They were chiefly active in Poland and Austria.

Piassava. See Fibrous Substances.

Piastre (Gr. and Lat. *emplastron*, 'a plaster;' in the Romance languages, anything spread out or flattened, 'a plate,' 'a coin'), an old Spanish



Piastre.

silver coin worth about 4s. It was divided into 8 silver reals, and hence was termed a *piece of eight*, the name invariably applied to it on the Spanish Main (see Dollar). The Italian piastre, or *scudo*, was an imitation of the Spanish coin, and was nearly equal to it in value. The Turkish piastre is a silver coin worth about 2d. in English reckoning and 4 cents in United States currency. Usually 125 piastres = £1 sterling and 100 = 20 francs. The lira contains 100 piastres. Pieces of 1, 2, 5, 10, and 20 piastres are struck in silver.

Piatigorsk, a town in Russian Caucasia, at the southern foot of Mount Beshtau (4587 feet), facing Mount Elburz and the Caucasus Mountains, and 124 miles by rail NW. of Vladikavkaz, is celebrated for its sulphur-springs. Ranging from 83·7° to 117·5° F. in temperature, they are useful for abdominal and rheumatic affections. Pop. 13,665.

Piatra, a town of Moldavia, 60 miles W. by S. of Jassy, romantically situated on the Bistritza, at the (eastern) foot of the Carpathians, has a trade in timber and a pop. of 13,890.

Piazza (more fully *Piazza Armerina*), an episcopal town of Sicily, 16 miles SE. of Caltanisetta. Pop. 17,038.

Piazzi, Giuseppe, Italian astronomer, was born at Ponte in the Valtelline, July 16, 1746, and entered the order of the Theatins at Milan in 1764. After holding professorial chairs of Philosophy, Mathematics, and Theology at Genoa, Malta, Ravenna, and Rome, he was appointed in 1780 to the chair of Mathematics in Palermo; and there, with the aid of government, he established an observatory in 1789. The first task he set himself to was to make a catalogue of the stars, published in 1803, and again extended in 1814. On the night of the 1st January 1801 he discovered a new planet, the first of the group of planetoids between Mars and Jupiter, and named it Ceres. He died, 22d July 1826, at Naples.

Pibroch (Gaelic, *Piobaireachd*, 'a pipe tune'), a form of bagpipe music, generally of a warlike character, including marches, dirges, &c. According to Sir Walter Scott, connoisseurs in pipe-music affect to discover in a well-composed pibroch the imitative sounds of march, conflict, flight, pursuit, and all the current of a heady fight. The rhythm is very irregular and difficult for a stranger to follow, but when played by a good piper it has a very powerful effect. The earliest mention of the military music of the bagpipe is in 1594 at the battle of Glenlivet, but the various pibrochs belonging to the different clans are mostly of modern composition.

See Macdonald, *Ancient Martial Music of Caledonia* (about 1805); Mackay, *Collection of Ancient Piobaireachd, or Highland Pipe Music* (1838); and Glen's *Collection of Piobaircachd*.

Picardy (*Picardie*), an ancient province in the north of France, was bounded on the W. by the English Channel, and on the E. by Champagne. The capital of this province was Amiens. The territory now forms the department of *Somme*, and portions of the departments of *Aisne* and *Pas-de-Calais*.

Picaresque. See Novels.

Picayune, a name derived from the Carib language, and used in Louisiana for a small coin worth 6¼ cents, current in the United States before 1857, and known in different states by various names (fourpence, fippence, fip, sixpence, &c.).

Piccolo. See Flute.

Piccolomini, an old and distinguished family of Italy, settled at Siena, who subsequently obtained possession of the duchy of Amalfi. It produced numerous celebrated *littérateurs* and warriors, one pope (see Pius II.), and several cardinals. One of the most illustrious members of this family was Ottavio, Duke of Amalfi, born in 1599. He entered the Spanish military service, and, being

sent to aid the Emperor Ferdinand II., fought against the Bohemians at the battle of the Weisse-Berg (1620), then in the Netherlands, and after that in Wallenstein's army at Lützen (1632). He was one of the chief agents in effecting the fall of the all-powerful general, by betraying his secrets to the emperor. Then he greatly distinguished himself in the battle of Nördlingen (1634). In the following season he was sent to aid the Spaniards in the Netherlands, and speedily drove out the French, but had not much success against the Dutch. He was withdrawn by the emperor in 1640 to stay the Swedes, who, under Banér, were threatening the hereditary possessions of Austria. This purpose he accomplished; but, though he was successful against these northern invaders in the Palatinate, he was worsted in Silesia by Torstenson. Returning to the Spanish service in 1643, he was sent again to the Netherlands to take the command of the Spanish troops. But his success was not nearly so decisive as before, the prestige of the Spanish infantry having been destroyed by Condé at Rocroi (1643). After the signing of the peace of Westphalia (1648) Piccolomini was created a field-marshal by the emperor, and was sent as plenipotentiary to the Congress of Nuremberg (1649). He died at Vienna, 10th August 1656, leaving no children; his son Max, who figures in Schiller's *Wallenstein*, is only a poetical fiction.

Pic du Midi, a summit of the Pyrenees, 9466 feet high, in the south-east corner of the French department of Basses-Pyrénées.

Pichegru, CHARLES, French general, was born a labourer's son at Arbois in Jura, 16th February 1761, and was educated by the Minorite friars at Arbois and at the college of Brienne. He enlisted into an artillery regiment in 1783, and showed such capacity and courage on the Rhine in the fiery service of the young republic that by 1793 he was a general of division. In October of that year he was given supreme command on the Rhine, and in conjunction with Hoche and his army of the Moselle he drove back the Austrians, relieved Landau, and overran the Palatinate. Next year he continued his career of triumph in the Netherlands, and showed in three campaigns within one year consummate generalship and a fortunate audacity worthy of the great Napoleon. After by swift movements defeating the Austrians in detail, he broke their forces at Fleurus, June 27, 1794, and, continuing the struggle into the winter, crossed the Meuse and the Waal on the ice, entered Amsterdam, January 20, 1795, and soon occupied the whole of Holland. During this campaign occurred the famous capture by the French hussars of the Dutch ships frozen in the Helder. Recalled to Paris by the Thermidorians, the 'Sauveur de la Patrie' crushed an insurrection of the *faubourgs* at Paris, 1st April 1795, next proceeded to the Rhine, and took Mannheim. But at the height of his fame he turned traitor, and sold himself for vast promises to the Bourbons. With deliberate treachery he remained inactive before the enemy, and allowed Jourdan to be defeated. The Directory becoming suspicious superseded him by Moreau, and Pichegru retired to Arbois. In 1797 he took his place, first as member, next as president, of the council of Five Hundred, and continued his Bourbon intrigues, but on the 18th Fructidor (4th September) was arrested and deported to Cayenne. Escaping in the June of next year, he made his way to London, was attached to the Austro-Russian army in 1799, and thereafter lived in Germany and England until the formation of the Bourbon conspiracy of Georges Cadoudal (q.v.) for the assassination of the First Consul. The pair reached Paris secretly, but found it impossible to gain over Moreau. They were soon betrayed to the police, and Pichegru was seized in bed and carried to the Temple, February 28, 1804. Here, on the morning of the 6th April, it was found that he had anticipated justice, and ended his dishonoured life with his own hands. The traitor knew that he had justly forfeited his life to his country's laws, and there is no justification for the royalist slander that he was made away with by Napoleon.

See the Lives by Gassier (1814), Pierret (1826), Vouziers (Dôle, 1870); also the *Mémoires* by Montgaillard (1804).

Pichiciago. See CHLAMYDOPHORUS.

Pichincha ('boiling mountain'), the most populous province (205,000 in 1896) of Ecuador, embraces the Quito plateau and its slopes. Area, 8300 sq. m. The soil is fertile in the west. The province takes its name from the active volcano of Pichincha, 8 miles NW. of Quito, the chief town. It has five peaks, two of which (15,918 feet) Mr Whymper ascended in 1880. The enormous crater, nearly a mile across at the top and perhaps 1500 feet in diameter at the bottom (which is 2500 feet below), is said to be the deepest in the world.

Pichler, KAROLINE, novelist, was born 7th September 1769, at Vienna, her maiden name being Greiner; and between 1800 and her death, 9th July 1843, published novels and dramas sufficient to fill a collected edition of 60 volumes, of which the most notable are *Agathokles* (1808), *Frauenwürde* (1808), and *Die Belagerung Wiens* (1824). Her autobiographical *Denkwürdigkeiten* (1844) fill 4 vols.

Pickerel. See PIKE.

Pickering, a market-town in the North Riding of Yorkshire, 32 miles NNE. of York. It has a fine ruined castle, which was Richard II.'s first prison, and was dismantled by the Roundheads, and an interesting parish church. Pop. (1881) 3931; (1891) 3676.

Pickles, a term generally applied to vegetables preserved in vinegar, with or without spices; though pickled applies to animal food preserved in salt (see PRESERVED PROVISIONS). The vegetables most pickled in Britain are cabbage, cauliflower, gherkins or young cucumbers, French beans, onions and eschalots, walnuts, mushrooms, and nasturtiums. *Piccalilly* or Indian pickle is made of cucumber, cauliflower, mustard-seed, and flower of mustard. For the methods of preparing pickles reference must be made to a cookery-book. Capers (q.v.) are imported; also olives preserved in brine and in vinegar, and several preparations of the mango fruit. The food value of pickles as a condiment is touched on at DIET, Vol. III. p. 809; and for adulterated pickles, see ADULTERATION.

Pico. See AZORES.

Pico della Mirandola, one of the most curious figures in the history of the Renaissance, was born in 1463, and was the son of Francesco Pico, Count of Mirandola and Concordia in the Modenese. He was a wonderfully precocious boy, and in his youth he visited the chief universities of Italy and France. In 1486 he issued a challenge to all comers to engage with him in public discussion at Rome, but the debate was forbidden by the pope on the score of the heretical tendency of certain of the nine hundred theses which Pico had offered to maintain. An *Apologia* which he issued in his defence exposed him to considerable persecution until Alexander III. in 1493 absolved him of the charge of heresy. He spent much of his life in travelling, and became known as a generous benefactor of the poor. He was an intimate friend of Politian and Lorenzo de' Medici. He died of fever in 1494, and Savonarola, who had been anxious to enrol him among the Friars Preachers, vested him

after death in the habit of the order. Mirandola was the last of the schoolmen. He endeavoured to reconcile the Catholic theology with mediæval philosophy, and his works are a bewildering compound of mysticism, scholasticism, and recondite knowledge. He interpreted the Mosaic text by the Neoplatonic doctrine of the microcosm and the macrocosm, and maintained that in natural magic lay the strongest testimony to the truth of the Gospels. He appealed to the authority of the Cabbalists and Pythagoreans as well as to the Apostles; he exhibited, along with a childlike credulity, an argumentative ingenuity worthy of the subtlest schoolman. He was a humanist as well as a theologian, and was the author of various Latin epistles and elegies and of a series of florid Italian sonnets. His writings are of little value, but the magic of his personality survives. A theologian and an erotic poet, a philanthropist, a scholar, and a traveller, an adherent at once of Duns Scotus and of Politian, he was one of the most chivalrous, generous, and versatile of men; his character is as engaging as it is curious and complex.

See *G. P. della Mirandola*, his life by his nephew (trans. by Sir Thomas More; Nutt, Lond. 1890), and Pater's *Studies in the Renaissance*.

Picotee. See CARNATION.

Picquet. See PIQUET.

Picric Acid (Trinitrophenol), $C_6H_2(NO_2)_3OH$. This substance appears in the form of pale yellow crystalline scales. It is obtained by the action of nitric acid on phenolsulphonic acid. Equal parts of phenol and concentrated sulphuric acid are mixed together, and placed in a suitable vessel, which is heated till the mixture reaches 212° F. (100° C.). Nitric acid of the specific gravity 1·3 is then added. On cooling, a crystalline mass is produced which is filtered and drained. A washing with cold water follows, and then the picric acid is further purified by recrystallising it from water containing a small proportion (0·1 per cent.) of sulphuric acid. Picric acid is easily soluble in hot, but only slightly in cold water. It is also soluble in alcohol and ether. Its taste is intensely bitter, and its tinctorial power is very great, the solutions of it having a strong yellow colour (see DYEING, Vol. IV. p. 141). It has been much used for dyeing silk, wool, and leather. As it does not adhere by itself to vegetable fibre, it serves for a test to distinguish cotton from wool or silk. The presence of cotton in a mixed fabric can therefore be detected by steeping it in a hot solution of the acid, and afterwards washing it. Then, with the aid of a microscope, the difference between the wool or silk, both of which retain the dye, and the cotton, which does not, will be made clear. The salts of picric acid are a very important ingredient in explosives (see MELINITE, GUN-COTTON, SHELL). It was formerly called Carbazotic Acid.

Picrite, one of the peridotites or olivine-rocks. It is particularly rich in olivine. The other principal minerals are augite and plagioclase. Magnetite or ilmenite, or both are generally present. Biotite occurs not infrequently, and apatite occasionally. The rock is often more or less altered into serpentine.

Pictet, ADOLPHE (1799–1875), a native of Geneva, and a writer on the Celts and the primitive Aryans. To the same Genevese family belong Marcus Auguste Pictet (1752–1825), physicist; François Jules Pictet (1809–72), zoologist and palæontologist; and Raoul Pictet, chemist and physicist, known in connection with the liquefaction of oxygen.

Picton, SIR THOMAS, British general, was born in August 1758, at Poyston in Pembrokeshire, entered the army as ensign in the 12th Foot in 1772, and two years later joined his regiment at Gibraltar. In 1794 he went out to the West Indies, and was given a command under Sir John Vaughan. He took part in the conquest of several islands of the West Indies, including Trinidad, and was appointed (1797) governor of the last named, being shortly afterwards raised to the rank of general. In 1803 he was superseded, but immediately after appointed governor of Tobago. He found it necessary, however, to return to England, to take his trial on a charge of having permitted, under the old Spanish laws, a female prisoner to be tortured. He was found guilty of sanctioning unlawful torture; but on appeal he was in a new trial acquitted. He saw active service again in the Walcheren expedition (1809), and was made governor of Flushing after its capture by the English. Early in the following year he was summoned to Spain, and put in command of the 'Fighting Division,' and with it rendered brilliant service at Busaco, during the subsequent expulsion of the French from Portugal, at Fuentes de Onoro, at the sieges of Ciudad Rodrigo and Badajoz, at Vittoria and in the battles of the Pyrenees, at Orthez and before Toulouse. Napoleon's escape from Elba once more called Picton into the field; he fought at Quatre Bras and was wounded, but kept the fact hidden that he might not miss the great day he saw coming, and he fell leading his men to the charge at Waterloo, 18th June 1815. See *Memoirs of Sir T. Picton*, by H. B. Robinson (2 vols. 1835).

Pictou, a port of entry on the north coast of Nova Scotia, on a large and sheltered harbour, 85 (by rail 114) miles NNE. of Halifax. The town contains several mills and factories, and coal, mined in the vicinity, is exported. Pop. 5000.

Picts. This is the name by which, for five and a half centuries (296–844 A.D.), the people that inhabited eastern Scotland from the Forth to the Pentland Firth were known. In the Irish chronicles they are generally styled Picti, Pictones, Pictores, or Piccardaig—all forms of the same root; but sometimes the native Gaelic name of Cruthnig is applied to them, and their country is called Cruithen-tuath, the equivalent of Latin Pictavia and Old Norse Pettland, which still survives in the name of the Pentland Firth. There were Cruithni or Cruthnig also in Ireland—never, however, called Picti. They formed the petty kingdom of Dál-araide (County Down and part of Antrim) and bordered on the Irish Dalriada; and, as the kinglets of both these provinces were contemporary with the whole extent of Pictish rule, much confusion is thereby caused as to what refers to Scotch and what to Irish Cruithnig in the annals. Other Irish Cruithnig appear sporadically, not to say enigmatically, in Meath and in Roscommon. There does not seem to have been any difference in language and customs between these Irish Cruithnig and the rest of the people of Ireland, at least in historic times. They were probably early invaders from Britain belonging to the Pictish race.

The Picts are first mentioned in connection with the campaigns of Constantius Chlorus in Britain in 296 and 306. Eumenius, his panegyrist, speaks of 'Caledonum aliorumque Pictorum silvas et paludes' (the Caledonians and other Picts), which implies the inclusion of the former in the latter people. Caledonia is the name given by Tacitus to Scotland north of the Firths of Forth and Clyde, and he describes the Caledonians as a noble race of barbarians, who fight in chariots as well as on foot, with long swords and short shields, and whose fair red hair and large limbs argued a German origin. Ptolemy (120) places fourteen tribes in Tacitus' Caledonia, inclusive of the Caledonians

themselves, and the more easterly ten of these may be claimed as Picts. So troublesome were these northern tribes to the Roman province that in 208 the Emperor Severus came to Britain and vainly attempted their subjugation. The contemporary historians mention only two tribes north of the Forth and Clyde wall—the Mæatæ and the Caledonii—and Tacitus' noble barbarians appear in their pages but squalid savages, having no cities, knowing no agriculture, possessing wives in common, and tattooing their bodies with pictures of all kinds, to show which 'they wear no clothing,' says Herodian. Yet they have chariots and weapons as described by Tacitus, with dagger and peculiarly knobbed spear. One hundred years later the Caledonians and other Picts, as already said, are encountered by Constantius, and still fifty years later they are harassing the Roman province (360) now in company with the Scots, who are first mentioned at this date, and who appear as great sea-wanderers, starting from Ireland and Scotland both, it would seem, and attacking the whole seaboard of the province, especially Wales. The Picts and Scots are helped in this 'continual vexing' of the Britons by the Saxons and Atecotti. The Picts are represented at this time as divided into two nations called Dicalidonæ and Vecturiones, or rather Verturiones, to accept Professor Rhys's happy emendation of Ammianus' text, for this latter form may be identified with the historic Fortrenn (Strathearn and Menteith). Theodosius the elder in 369 subdued these northern foes and restored the district between the walls to Roman Britain, and the usurper Maximus signalised his assumption of power in 383 by an energetic campaign against the Picts and Scots. During the next quarter of a century the Romans were losing their hold on Britain, and their northern foes pressed on the province with great persistence. First the northern wall was rebuilt, then abandoned; and lastly the southern wall was repaired by the last legion sent. In vain did the brave Stilicho gaze on the 'figures fading on the dying Pict,' as Claudian says, for they burst on the Romanised Britons with more fury than ever, and the calling in of the Saxons against the Picts and Scots made the last state of the Britons worse than their first.

At this point the light of Roman history is withdrawn from us, and we have to depend on vague references in native writers—on Gildas of Wales (6th century), on Adamnan (704), on Bede (731), on Nennius (9th century), and on the Irish and other annalists of the middle ages, the best of whom is Tigernach (1088). There is a Pictish Chronicle, perhaps composed in the 10th century, but preserved only in a MS. four hundred years later in date. Gildas describes the Picts and Scots as 'differing somewhat in manners,' and 'shrouding their villainous faces in bushy hair rather than clothing' their lower limbs. Bede points out that the Picts are divided into a southern and a northern division by the Grampians. The southern Picts were converted to Christianity by St Ninian (*circa* 400), and the northern Picts over a century and a half later by St Columba. Bede also notes and mythically explains the system of succession among the Picts, whereby the reigning monarch was succeeded not by his son but by either his brother or his sister's son, descent being counted through the females. This curious rule is amply confirmed by the Pictish list of kings. Scotland in Bede's time, and for more than a century previously, was divided among four nations: the Saxons and Britons were south of the Firths, and north of them were the Picts east of Drumalban, and the Scots to the west with Dalriada or Argyllshire as their head centre. The annals say little of the Isles and north-west coast, whether they were held by Scots or Picts, though subsequent history makes it clear that the Scots had long colonised them, for the sons of Erc in 501 were but the last of many Scottic invaders and colonisers. That the four nations of Bede's day spoke four different languages is clear from his oft-repeated statement to that effect, and his handing down a word in this Pictish tongue (*pcanfahel*). Columba, according to Adamnan, had to employ an interpreter twice in dealing with the Picts, while Cormac of Cashel mentions a word (*cartit*) belonging to the *berla cruithnech* or Pictish language.

In the ninth year of the reign of Brude Mac-Mailchon, the year 563, Columba landed in Scotland to convert the Picts. Brude had his royal residence near Inverness, and was 'a most powerful king,' Bede says, for he represents him as granting Iona to Columba, though Tigernach says that Conall of Dalriada made the gift. But the Picts were carrying on war among the Isles at the time, as the life of St Comgall shows, and Brude had hostages from the king of the Orkneys. Brude's successor, Gartnait, seems to have fixed his capital at Abernethy, the church of which he founded. The Picts were subjugated by Oswald, king of Northumbria, and made tributary by his brother Oswiu after 654. They remained under the Anglian yoke for thirty years; but Brude, son of Bile, asserted his rule among the northern Picts, and meeting the Anglian king Ecgfrid at Dunnichen in 685 defeated and slew him, and thus ended the Anglian rule over the Picts. About 710 Naiton or Nectan, son of Derile, was king of the Picts, and, as Bede tells us, he conformed under Anglic influence to the Roman Church in regard to the celebration of Easter, going indeed so far as to expel recalcitrant Columban clerics across Drumalban. Following a custom not unfrequent at the time, Nectan resigned his throne and became a cleric. A fierce struggle ensued for the throne, during which Nectan emerged from his monastery, but eventually Angus, son of Fergus, petty king of Fortrenn, crushed all his rivals and reigned for thirty years, when this 'sanguinary tyrant' died in 761. His brother Brude died king of Fortrenn in 763, for evidently Angus' monarchy had collapsed and the provincial kings again came to the front. Unfortunately the next eighty years of Pictish and Scottish history is exceedingly difficult to unravel, for only lists of kings and a reference or two in the Annals of Ulster are all the material which is to hand. Ciniod was king after Brude, but his rights were disputed by Aed of Dalriada; and after his death in 774 there is much confusion in the Chronicles, as there must have been in the facts. Dalriadic princes struggle with Pictish princes and with one another for the throne, till Constantine of Dalriada established himself about 815 as king over both. His and his brother's reign ended in 834, and a time of confusion followed, native Pictish princes striving against Eoganan of Dalriada, and he ultimately succeeding. The year 839, which ended his reign, saw a great defeat and slaughter of the Picts by the Danes, with confusion once again, from which emerged in 844 Kenneth MacAlpin, the Scot, as king over both nations, henceforward not to be disunited. Many things contributed to the overthrow of the Pictish kingdom, such as it was, and of the Pictish language: the disunion, physical and otherwise, between northern and southern Picts; the rule of female succession which allowed Anglic, Briton, and Scottic princes to rule in right of their mothers, with the consequent degradation of marriage which matriarchy implies; and the superior culture of the Scots, Christian and literary. Nor must it be forgotten that we really do not know much about

the Isles and west coast north of Argyll, nor indeed of the counties north of Inverness, from the time of Brude MacMailchon till the Norsemen came. It is quite certain that the Scots colonised these very early, and had, indeed, established themselves in Perthshire. Aidan, the son of Gubhran, makes expeditions to Orkney, and fights the Picts and defeats them on the Forth, or even farther eastward, in Mearns. This aggressive energy, combined with the other facts of the situation above enumerated, would easily enable the Scots to supersede the Picts in power and language.

The real 'Pictish question,' however, is what the language was which they spoke. This question must not be confused with another if allied one, What race did the Picts belong to? The Picts may have spoken a Celtic language though racially possessed of little Celtic blood, and may have retained non-Celtic customs as survivals of a lower culture, as indeed they did in the case of female succession. Four hypotheses have been formed in regard to the language and origin of the Picts. The first, started by Pinkerton and put by Sir Walter Scott into the mouth of the 'Antiquary,' is that they were Teutons, speaking a Gothic dialect; the second, maintained by Dr Skene, is that they were Gaelic-speaking Celts, and that they and not the Scots finally conquered in the 9th century; the third, due to Professor Rhys, is that the Picts were non-Aryans, whose language was overlaid by loans from Welsh and Irish; and the fourth, held by two of the most eminent Celtic scholars of the day, Professor Windisch and Dr Whitley Stokes, is that they were Celts, but more nearly allied to the Cymry than to the Gael.

The materials for deciding the linguistic relations of the Picts, though fairly abundant, consist almost entirely of names—those in the classical writers, in the king lists, and in the Book of Deer, and the still or lately existent place-names of ancient Pictavia. The main agreement between the Gallo-Cymric and Gaelic languages is their dropping of Aryan initial *p;* their main difference is their developing the labialised guttural *qu*—the one like the Greeks into *p*, and the other, the Gaelic, like the Latins into *q* or *c*. This fact led Professor Rhys to call them respectively P Celts and Q Celts. No native initial *p* exists in old Gaelic language. The name Picti, which was usually regarded as the Latin for 'painted men,' is now considered inseparable from Pictones or Pictavi of Gaul, now Poitou, and is therefore Celtic of the P group. An old Gaelic equivalent is supposed to exist in *cicht* ('engraver'), which leaves the old idea of 'painted or pictured men' intact. Further, the Gaelic name *cruthni* is derived from *cruth* ('form, figure'), Welsh *pryd;* and the Welsh name for Pict is actually Prydyn. The form Prettania, undoubtedly used by the best Greek writers for the Latin Britannia, makes it possible that the Cruthnig gave their name to Britain. The meaning of Bede's Pictish word *peanfahel* is practically explained by himself as Wall's Head, where *pean*, with its *p*, answers to Welsh *penn* ('head') and not to Gaelic *cenn*. Similarly *Pern* and *pant* in the king lists belong to the P group; but more striking still is the *pett* of the Book of Deer, which signifies 'a portion of land,' corresponding to Welsh *peth*, and, etymologically to Gaelic *cuit* ('portion'). *Pet* or *pit* is a prefix in place-names in Pictland from Sutherlandshire to the Forth at the present day, some two hundred being easily counted, though the Gaelic *Bal* has considerably extruded it in western Pictland. It is similar to *Aber* as a place-name prefix, which is found all over Pictland. This is the Abbor or Apor of the Book of Deer and the Chronicles, and corresponds only to Welsh *Aber*, older *Aper*, 'a confluence.' Minor points in the phonetics of the Pictish names are the preservation of *st* and *nt* as in Cymric; *ch*, as in Ochil, Welsh Uchel, but Gaelic Uasal; *it*, in Naiton, for Gaelic Nectan, being Cymric; Elphin for Alpin or Albin; Bridei for Brude, where *u*, as in Welsh, changes to *i;* the Cymric forms of the prefix *ur* or *wr* for Gaelic *for* or *fer;* and others. Names like Talorg and Morcunn remind us of Gaulish Argio-talus, 'silver-brow,' and of Welsh Morgan. Modern place-names like Dee ('goddess'), Don for Divona ('goddess'), Tay, Eden, Nith or Nethy, and Ythan can hardly be paralleled outside Gallo-Cymric ground. The *sp* of Spey and Spean is evidence of non-Gaelic origin. Dr Whitley Stokes, who has brought together in a list all the extant Pictish words from Tacitus down to the mediæval annalists in his work *On the Linguistic Value of the Irish Annals*, sums up the philologic arguments with sufficient temperateness thus: 'The foregoing list of names and other words contains much that is still obscure; but on the whole it shows that Pictish, so far as regards its vocabulary, is an Indo-European and especially Celtic speech. Its phonetics, so far as we can ascertain them, resemble those of Welsh rather than of Irish.' The conclusion to which we come is that the Picts, whatever traces they show of a non-Aryan racial element, with its consequent survival of lower ideas of marriage-laws, spoke a Celtic language belonging to a branch of Celtic allied to the Cymric, but dialectically different from the Welsh of Bede's time; and that this dialect of the Gallo-Cymric stock was a wave of Celtic speech from the Continent previous to the Gaulish which held England when Cæsar entered Britain.

See Skene's *Chronicles of the Picts and Scots* (Edin. 1867), where all the post-classical material is brought together, and his *Celtic Scotland*, vol. i. (Edin. 1886); Professor Rhys's *Celtic Britain* (Lond. 1884), and his Rhind Lectures for 1889 in the *Scottish Review;* Dr Whitley Stokes's work above mentioned; Professor Windisch's article, 'Keltische Sprachen,' in Ersch and Gruber's *Encyklopädie;* Adamnan's *Columba* (Edin. 1874); Hennessy's *Annals of Ulster* (Dublin, 1887); Bede's *Ecclesiastical History* and the other documents in the *Monumenta Historica Britannica;* Father Innes' *Critical Essay* (1729; new ed. Edin. 1879); and Pinkerton's *Inquiry into the History of Scotland.*

Picts' Houses, the name popularly given in many parts of Scotland to the rude underground buildings, more commonly and accurately called Earth-houses (q.v.). The Brochs (q.v.) are also sometimes called Pictish Towers. For the Picts' Work, see CATRAIL.

Piedmont, or PIEMONT (Fr. *pied*, 'foot,' *mont*, 'mountain'), a former Italian principality, which now forms the north-west part of the kingdom of Italy, is by the Alps separated from Switzerland on the N. and from France on the W.; on the E. lies Lombardy, and on the S. Liguria and Genoa. It included the duchy of Monferrat and part of the old duchy of Milan, and now embraces the provinces of Alessandria, Cuneo, Novara, and Turin, and covers 11,389 sq. m., with a pop. (1889) of 3,297,157. For an account of its geographical features, see ITALY. From the end of the 12th century the name Piedmont was used as a collective title for the territories ruled over by the House of Savoy on the east side of the Graian and Cottian Alps; the history of the region will be found under ITALY, SARDINIA, SAVOY, and WALDENSES. See, too, S. Butler's *Alps and Sanctuaries of Piedmont* (new ed. 1890).

Piepowder Court, in England, an ancient court held in fairs and markets to administer justice in a rough and ready way to all comers, called also the Court of Dusty Foot (Old Fr. *pied pouldré*). Its jurisdiction seems to have been confined mostly to petty vagabonds, pedlars, and other wanderers. The court has long been obsolete, its jurisdiction merged in the court of Petty Sessions (q.v.).

Pierce, Franklin, fourteenth president of the United States, was born at Hillsborough, New Hampshire, November 23, 1804. His father, Benjamin Pierce, a farmer who had risen in the war of independence to the rank of major, in 1827 and 1829 became governor of New Hampshire. Franklin Pierce was educated at Bowdoin College, and was an officer in a college military company, in which his biographer, Nathaniel Hawthorne, was a private. He graduated in 1824, studied law, and was admitted to the bar in 1827. From 1829 to 1833 he was a member of the state legislature, and for two years was its speaker; he was then elected to congress, a Democrat of the school of Jackson. In 1837 he was elected to the United States senate, of which he was the youngest member. In 1842 he resigned his seat, and returned to the practice of law. He refused the Democratic nomination for governor, as well as an appointment to fill a vacancy in the senate; and he declined the office of attorney-general offered him by President Polk. He remained, however, among the leaders of his party, zealously advocated the annexation of Texas, with or without slavery, and, after his opponents, the Whigs and Free-soilers, had been victorious at the polls in 1846, volunteered as a private for the Mexican war. The president made him a brigadier-general, and in August 1847 he joined General Scott, and led his brigade in the battles of Contreras and Churubusco. In 1852, in consequence of the conflicting claims of the leaders of the Democratic party at the Baltimore Convention, he was nominated as a compromise candidate for the presidency, against General Scott, the Whig nominee, and received the votes of all but four states. President Pierce in his inaugural address defended, on constitutional grounds, slavery and the Fugitive Slave Law; and his cabinet, which was an eminently able one, included Jefferson Davis as secretary of war. Pierce's view as to slavery was that it was the price paid for the Union by the framers of the federal constitution, and that, therefore, in honesty it must be maintained. The principal events of his administration—in importance far before the treaty for reciprocity of trade with the British American colonies and the treaty with Japan, or the filibustering expeditions of Walker (q.v.) to Nicaragua and of others to Cuba, with the resultant abortive Ostend (q.v.) Manifesto—were the repeal of the Missouri Compromise (see Missouri) and the passing of the Kansas-Nebraska Act (see Kansas), which kindled a flame of civil war in the new territory that ultimately set the whole Union in a blaze. Pierce, with his rigid regard for constitutional obligations, was intensely hostile to the free-state settlers and to abolitionists in general. At the close of his term of office in 1857 he spent three years in Europe; and afterwards, having no sympathy with the party which subsequently came into power, he took no part in politics. He died at Concord, 8th October 1869. As a lawyer Pierce was an eminent and eloquent pleader; as a statesman his administration would have passed for skilful and successful had it not been for the slavery storm which rose and wrecked it; while as a man he was amiable and generous, and of spotless integrity. There are Lives by Hawthorne (1852) and D. W. Bartlett (1852), and a Review of his administration by A. E. Carroll (1856).

Pieria, a coast district of ancient Macedon, at the base of the Olympus, and between the Peneus and Haliacmon. It was the fabled birthplace of the Muses and of Orpheus.

Pierre, the capital of South Dakota, is a small town in the centre of the state, on the Missouri River, at the mouth of Bad River, 781 miles by rail WNW. of Chicago.

Pierson, Henry Hugo, composer, was born at Oxford in 1815, in 1844–45 filled the chair of Music in Edinburgh, and from 1846 lived in Germany, dying at Leipzig, 28th January 1873. Among his works were the music for the second part of Goethe's *Faust*, the operas *Leila* and *Contarini*, and the oratorios *Jerusalem* and *Hezekiah*.

Piers Plowman. See Langland.

Pietà (an Italian word signifying *piety*, in the sense in which that term indicates or includes affection for relatives), the name given in the language of art to representations of the Virgin Mary embracing the dead body of her son. It is a counterpart to the *Madonna* with the infant Jesus in her arms.

Pietermaritzburg, or Maritzburg, capital of Natal (q.v.), occupies a fine situation near the Umsundusi river, 54 miles N. of Durban, and 2218 feet above sea-level. The chief buildings are the Legislative Assembly Buildings, Government House, the Colonial Offices, Town-hall (rebuilt 1899, after being burnt), the supreme court, the post-office, railway station, police barracks, &c. Fort Napier, the headquarters of the imperial troops, overlooks the city from a hill on the south-west. There are a college library and museum, asylums, a park, botanical gardens, &c. The city takes its name from its founders (1839), the Boer leaders Pieter Retief and Gert Maritz. There is railway connection with Durban, with the Orange Free State, and with Johannesburg and Pretoria in the Transvaal. The place has steadily increased in importance with the development of the colony, especially since the establishment of the railways. Pop. (1887) 15,767; (1898) 24,595, about half whites, the rest Kaffirs and Indian coolies.

Pietists, a designation given at the end of the 17th century to a religious party in Germany, which, without forming a separate sect, was distinguished rather by fervour and zeal than by peculiarities of religious opinion. See Church History, Vol. III. p. 240, the articles on Spener and Francke; and the Histories of Pietism by Heppe (1879) and Ritschl (1880–86).

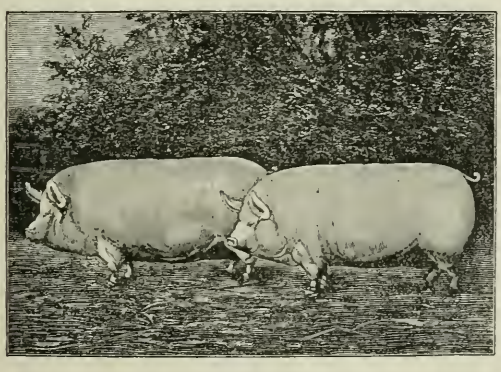
Pietra-dura, a name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as jasper, carnelian, amethyst, agate.

Piezometer (Gr. *piezō*, 'I press,' *metron*, 'a measure'), an instrument for measuring the compressibility of fluids, by observing the extent to which an air-bubble which marks the upper level of liquid in the capillary neck of a flask is depressed by the application of an external pressure acting through liquid surrounding the flask.

Pig, or Hog (*Sus*), a genus of artiodactyle ungulate mammals, of the family Suina (see Boar, where the characteristics of the wild species are discussed, with an illustration). The term Swine is commonly applied to the genus in Britain. The body is covered more or less with bristles and hairs; the skin is very thick; the limbs short and stout; the neck, which is carried straight forward from the trunk, is very thick and strong; the face moderately prolonged and truncated, always terminating in a movable cartilaginous disc, furnished, as in the mole, with a special small bone, and employed with wonderful expedition in

turning up the soil in search of roots and other food. In most of the improved varieties the face is much shorter than in the wild boar or ancient pig. There are six incisors, two canine teeth, and fourteen molars in each jaw, the lower incisors projecting forwards; the canine teeth long and strong, projecting and curved, becoming formidable tusks in wild boars, and large and powerful even in the females in a wild state. The feet have each four toes, the lateral ones small, and scarcely touching the ground, all separately hoofed. The tail is short. The stomach shows mere traces of division. The food is chiefly vegetable, but perhaps no animals may more properly be called omnivorous; and although, even in a wild state, pigs are not to be reckoned among beasts of prey, they not unfrequently, even in domestication, kill and eat small animals that come in their way, as many a housewife has had occasion to observe in respect to chickens. The Common Pig (*S. scrofa*) appears to be a native in the wild form (see BOAR) of most parts of Europe and Asia; the domestic European breeds are apparently descended from the European wild boar, crossed with domesticated Asiatic breeds. Like the other thick-skinned animals with which it is allied—the elephant, rhinoceros, hippopotamus, and tapir—the pig delights in humid and shadowy places. The pig usually grows until five years old. Its natural life ranges from fifteen to thirty years. Although the use of its flesh was prohibited to the Jews, and the prohibition has been adopted in the Mohammedan law, the pig has been a domesticated animal from a very early period, and its flesh constitutes a large part of the food of many nations. The fecundity of the pig is great; with proper treatment it will produce two litters annually, generally of four to eight pigs each, although sometimes there are as many as fourteen in a litter. Vast quantities of the flesh are consumed in various forms, as pork fresh or salted, bacon, ham, &c. Brawn (q.v.) is an esteemed luxury. The fat of the pig, which is produced in a thick layer under the skin, is an important article of commerce, and of various use under the name of Lard (q.v.). The skin of the pig is made into leather, which is particularly esteemed for saddles. The bristles, especially of the wild boar, are much used for brushmaking. Indeed, there is no food-producing animal which is of greater benefit to mankind than the pig.

There are numerous varieties of the domestic pig. Some have erect and some pendant ears, and those are most esteemed which exhibit the



Improved Yorkshire Pigs.

greatest departure from the wild type, notably in shorter and less powerful limbs, less muscular and more rounded forms, wider ribs and greater wealth of flesh. The *Chinese* breed and the *Neapolitan* have been of great use in the crossing and improving of the breeds commonly reared in Britain, giving rise to the improved white and black breeds respectively. The Chinese breed is renowned for its fertility, as well as for the rapidity with which, without materially increasing in offal or bone, it lays on flesh. Its head is short and thick, ears erect, legs very short, chine high and broad, and jowl wide, belly hanging very near to the ground. As a rule it carries a small quantity of hair. The skin is usually dark, but the flesh is delicate and white. These valuable characteristics distinguish the improved Yorkshire pigs which are now so much esteemed all over the British Isles as well as in several foreign countries. The Neapolitan breed is entirely black, with little hair, moderately short in the face, ears small and erect, short in the leg, moderately long and thick in the body, remarkably easy to fatten, but scarcely so robust in constitution or so prolific as the Chinese pig.

Besides many local varieties of recognised merit, there are at least six improved breeds of swine reared extensively in the British Isles. The White Yorkshire are divided into the three sub-varieties known as the Large, Middle, and Small White Breeds. Then there are the black Berkshire, the Suffolk breed (some black and others white), and the red Tamworth. The black Suffolk pigs are sometimes spoken of as the Small Black breed. The Tamworth is a large-sized pig, rather stronger in the bone than the other sorts, with a long face. It is noted for a high proportion of lean meat. The Large White is the most widely distributed variety. It is being used extensively and with excellent results in the improvement of the pigs in Ireland, Scotland, and on the continent of Europe. The pigs of America are descended mainly from the Berkshire, Poland-China (a breed developed in 1816–38), white Suffolk, Chester, Cheshire, Essex, Jersey red, and Victoria (a breed originating at Saratoga about 1855). The first swine seem to have been introduced into Hayti by Columbus in 1493, and into Florida by De Soto in 1538; within a century pigs bred in Virginia, Canada, and Nova Scotia. The extent of the pork-packing business in America may be estimated from the figures given at CHICAGO. See also PORK. It used to be said that pigs were indigenous in the Polynesian area, but most likely they were introduced by the earliest navigators. Allowed to run wild, they multiply rapidly under favourable conditions; thus in New Zealand they became at one time a nuisance, and in Nelson province three men killed 25,000 pigs in twenty months.

Pigs are profitably kept wherever there is much vegetable refuse on which to feed them, as by cottagers having gardens, farmers, millers, brewers, &c. They are often allowed to roam over fallow ground, which they grub up for roots, and over stubble-fields, which they glean very thoroughly. It was an ancient practice to allow pigs to feed in woods, where they consumed acorns, beechmast, and the like. When they are fed, as is sometimes the case, chiefly on animal garbage, their flesh is less palatable and less wholesome. The pig has a reputation, which it does not deserve, of peculiar filthiness of habits. It is true that it wallows in the mire, as the other pachydermata also do, to cool itself and to provide itself with a protection against insects, and it searches for food in any puddle; but its sleeping-place is, if possible, kept scrupulously clean. The too common filthiness of pigsties is rather the fault of their owners than of their occupants; and a clean and dry sleeping-place is of great importance to the profitable keeping of pigs.

The Hog Cholera or Swine Plague, due to the presence of a bacterium, caused terrible havoc in the United States in 1870–80, though hardly

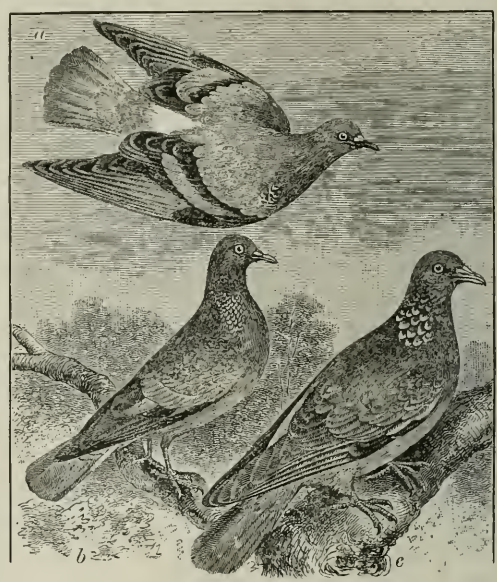
known twenty years before. As in the splenic fever of sheep, due also to bacteria, attempts have been made to ward off the more violent form of the disease by inoculating animals with a milder type.

The pig is not inferior to other quadrupeds generally in intelligence, but it excels most of them in obstinacy. It can be easily rendered very tame and familiar. Its acuteness of scent has been turned to account in making it search for truffles; and a tale is told of a pig having been successfully used as a pointer. The pig has sometimes served as a beast of draught.

The *Bosch Vark*, or Bush Hog of South Africa (*Choiropotamus africanus*), is about 2 feet 6 inches high, covered with long bristles; it has projecting tusks, a large callous protuberance on each cheek, and long, sharp, tufted ears. It is gregarious, subsists chiefly on vegetable food, and makes destructive inroads on cultivated fields. The forests of the island of New Guinea produce a species or variety of pig (*S. papuensis*) more widely different from the common pig than its breeds are from one another. It is 18 or 20 inches high, with short ears, and very short tail. The Babiroussa (q.v.) is another species of pig; see also WART-HOG.

See Coburn, *Swine Husbandry* (New York, 1877); Gilbert, *Pig-keeping for Amateurs* (1882); Long, *Book of the Pig* (2d ed. 1889).

Pigeon (Ital. *pigione*, *piccione*, or *pipione*, from *pipiare*, Lat. *pipire*, 'to peep or cheep'), a name sometimes applied, like Dove (q.v.), to all the species of Columbidæ, and sometimes almost restricted to those still included by ornithologists in the genus Columba; having a bill of moderate length, hard, and a little arched at the point, the base of the upper mandible covered with a soft thick skin, in which the nostrils are pierced; the feet with toes divided to the base, and formed both for walking and perching; the wings rather large and pointed; the tail of moderate length, and generally square at the end. The species of this group are very numerous, there being nearly 150 different kinds, and they are found in all parts of the world. Some of them build their nests in trees, and others in rocks. They invariably lay only two eggs at a time, but breed several times in the year, both the male and the female taking part in the process of incubation, as also in that of feeding the young birds. The origin of all the domesticated varieties of the pigeon is the Blue Rock-pigeon (*C. livia*), the *Biset* of the French, a bird of extensive geographical range, being found as far north as the Faroe Islands, and in nearly all parts of the eastern hemisphere. It is found in large numbers on the British coast, particularly on the Orkney Islands and the Hebrides, and also in the Mediterranean. Its food consists partly of molluscs and other small animals, and partly of grain and seeds; and it often pays unwelcome visits to the cornfields within its radius. In a wild state the blue rock-pigeon exhibits great uniformity both of size and plumage; it is not quite 12 inches in length from the tip of the bill to the end of the tail; the prevailing colour is bluish gray, in some parts with green and purple reflections, and having two broad and distinct black bars across the closed wings; the lower part of the back is whitish; the tail is a deep gray with a black bar at the end; the bill is dark brown; the legs and feet reddish orange. There are also the Stock-dove or Smaller Wood-pigeon (*C. œnas*), found all over southern and mid Europe, a species found in woods; and the Ring-dove, Wood-pigeon, or Cushat (*C. palumbus*), very common in all parts of Europe and Asia and in northern Africa, and the largest of the British species. These are all the British species of pigeon. In addition we may mention the Ring-tail Pigeon (*C. caribbea*), a West Indian species; the Bald-pate or White-headed Pigeon (*C. leucocephala*), also found in the West Indies and Florida; the Double-crested Pigeon (*C. dilopha*),



a, Rock-dove (*Columba livia*); *b*, Stock-dove (*C. œnas*); *c*, Ring-dove (*C. palumbus*).

found in the northern parts of Australia, and having, as its name indicates, a double crest, one half on the back part of the head, and the other springing from the forehead. There are other varieties, too numerous for mention.

As already stated, only the blue rock-pigeon has been domesticated, but this species lends itself very readily to the restrictions of civilised life. The changes brought about in it are very varied and remarkable; and the description of his experiments upon the pigeon by Darwin are of the deepest interest. For many centuries and in all lands pigeon-breeding has been a favourite pursuit with all classes of society. In India several of the native rulers have very extensive establishments for the breeding of pigeons. In Persia and in Asia Minor the pigeon is very largely and carefully bred; and in the latter country especially many of our most beautiful varieties have been produced. From North Africa we have also received at least one fine breed. Throughout Europe this pursuit is followed with a great amount of enthusiasm, more especially in Italy, Germany, France, and Belgium, as well as the United Kingdom. In Belgium the sport of pigeon-flying or racing is the national sport engaged in by all sections of the community; and to that country we owe the variety known as the Homing Pigeon (see CARRIER PIGEON). In the United Kingdom, as in America, there are enormous numbers of breeders who devote themselves to what are known as 'fancy pigeons,' by which term are known those bred for their special points or characteristics. Of these there is a great and ever-increasing variety, which it is impossible to describe in detail, as there are in all some two hundred breeds, many of which have several distinct colours. The following are some of the most prominent: *Carrier* (q.v.).—This is not, as is commonly supposed, a member of the homing family, though undoubtedly it was at one time used to carry messages. It is much longer in feather than

the blue rock, and is specially characterised by having an abnormal development of the beak and eye wattles, the former of which is like a round fleshy ball pierced by the beak. *Dragon.*—Of a similar type, rather lighter in body, and with less heavy wattles. *Barb.*—A heavy-wattled pigeon; but in this case the eye-wattle is the chief point, and it is bred so that the head has the appearance of a bobbin or reel. These three varieties make up the *Wattled Pigeons;* and they are all very valuable when bred to perfection. *Pouters.*—The Pouting Pigeon is equally high class, the name arising from the great development of the crop, which has a globular form, and stands out from the neck. Of these the best known is the English Pouter; and there is also the Norwich Cropper; the former a large bird, and the latter a smaller one. The smallest of this family is the diminutive Pigmy Pigeon. In these the head, which is at the back of the crop, is often almost buried by it. *Jacobin.*—A breed in which the head and neck feathers are largely developed, the former in the shape of a hood, so that the head is often buried within it, and the latter falling on to the shoulders, leaving a round space between, known as the rose. *Fantail.*—In this the characteristic which gives the variety its name is that the tail-feathers spread themselves out transversely to the body in the shape of a fan, and in good specimens evenly so. The head is thrown back, often touching the tail, with a nervous motion, the body poised on short legs, and the bird looking as if it were falling backwards. *Tumblers.*—In these the name is derived from the tumbling or turning motion when flying in the air, and good well-trained birds have been known to remain on the wing for many hours without cessation. They are divided into two sections—viz. Flying Tumblers—i.e. those which are bred for this quality, and Fancy Tumblers, in which the propensity is lost or suspended through disuse. A very valuable breed is the Short and Long Faced Tumbler, of which there are several varieties, notably the Almond, so called from its rich coloured plumage. The Nun and the Magpie are supposed to be descended from the same family. Allied to the flying tumblers are the Rollers and the Tipplers. *Frilled Pigeons.*—These include a very large variety, the greater portion of which originated in the Orient. They are thus called because the throat or chest is decorated with a frill of curled feathers, more or less perfect. Some have in addition a crest on the head, and there is an almost endless variety of colour and of markings, the richest—those known as Oriental Frills—being of much later introduction than the Owls and Turbits. One, the White African Owl, is the smallest of all domestic pigeons, and comes from Tunis. *Antwerps.*—A very massive-built bird in which there is a considerable admixture of homer blood. Of the other prominent varieties the homer has already been referred to; the Russian Trumpeter has a large crest and very profuse leg-feathering; the Runt is the largest of all pigeons, and on the continent of Europe is extensively bred for the table. The system of exhibitions which has grown up of late years has done much to stimulate the breeding of fancy pigeons, and very high prices are paid for the best specimens. On numerous occasions £100 has been given for a single pigeon, and £50 is quite a common price.

For the keeping of pigeons different forms of houses may be adopted. When they are permitted to fly about they may have either small cotes for, say, four pairs, mounted on tall poles—and these can be made very attractive—or they may be accommodated in larger houses. Fancy pigeons are usually restrained by what are called flights or aviaries, which consist of a large space attached to the house, the sides and top made of wire-netting, so that the birds cannot get away. It would be too great a risk to permit valuable birds to fly. Whether in confinement or at liberty each pair of pigeons must be supplied with a nest of their own, which is better if double, as often they are sitting on eggs and feeding young pigeons at the same time. In the nest-boxes pans are placed of the usual construction for this purpose. Pigeons are prolific breeders, and will lay several nests during the year, each time a couple of eggs. The male and female, if permitted to do so, continue faithful to each other from year to year, a circumstance noted by Pliny and others of the ancients.

See Dovecot, and books on pigeons and pigeon-keeping by Tegetmeier (1868), Piper (1871), Foulton (1876), Brent (1878), Wright (1879), Lucas (1886), Ure (2d ed. 1889), Lyell (1889), and the present writer (1891).

Pigeon-shooting. In the days of the Red House, at Battersea, the members met four times a week in their enclosure on the banks of the Thames for the purpose of pigeon-shooting. The traps mostly in use at that time were what were known as 'H' and 'T.' Betting was frequently heavy when men like Lord Huntingfield, Lord Winchelsea, Lord Kennedy, Sir Richard Sutton, Sir Charles Kent, Captain Ross, and Mr George Osbaldeston were present. Captain Ross in 1828 killed at 30 yards rise, from five traps, seventy-six birds out of eighty; three of the other four settled on the fence, and the fourth bird was hard hit, although the shooter's first barrel missed fire. The shooter handled a 12-bore gun by William Moore, charge of powder and shot unlimited. Captain Ross won the Red House Club Cup, value 200 guineas, both in 1828 and 1829; and in 1841, in a match at Edinburgh with Lord Macdonald, he at 35 yards rise killed fifty-two birds out of fifty-three. When the Red House Club was closed in 1850, trap-shooting was for some years out of fashion, until it occurred to Mr Frank Heathcote that a system of handicapping might be advantageously adopted in order to place good and bad shooters on something like an equality. Many successful meetings were now held under Mr Heathcote's management at the Old Hornsey Wood House, until the ground was wanted for building and other purposes. Mr Heathcote in 1867 rented for £700 a year the Hurlingham estate at Fulham (q.v.); and a club being formed, the property was subsequently purchased for £20,000. After the appointment of Captain the Hon. D. J. Monson to the post of manager, the club flourished to such an extent that for several years prior to 1891 it had its full complement of 1500 members, under the presidency of the Prince of Wales. As regards the shooting members there are not more than 200, and fully half of these never fire at a pigeon. This can easily be accounted for, as a gentleman can get himself elected almost immediately as a shooting member, whereas in the ordinary ballot for members he might have to wait two or three years. In 1891 over 200 candidates were down for election. The entrance-fee is 15 guineas, with an annual subscription of 5 guineas. The polo-ground is the best in the country, and during the height of the London season it is nothing unusual to see three or four thousand of the élite of London society in the park and grounds.

Pigeon-English. See China, Vol. III. p. 195.

Pigments used in artistic work vary much in permanence; not a few of the pictures painted by distinguished artists during the 18th and the first half of the 19th century are already more or less faded by the action of light or otherwise injured by impurities in the atmosphere of rooms. It is

imprudent to expose any kind of artistic work in colours to direct sunlight or even, it would seem, to the light of electric arc lamps. The following refers to the durability of pigments employed in oil-painting, when continuously exposed to fairly strong daylight. Among blue colours, ultramarine, both real and artificial, is permanent; while Prussian blue is liable to some change, and indigo is fugitive. Among red colours, vermilion and the red ochres are perfectly durable; while the madder reds and purples can hardly be so thoroughly relied upon, and the carmine and crimson lakes, from cochineal, quickly give way. Among the yellows, raw sienna, yellow ochre, as well as the cadmium and Naples yellows, are quite stable; while Indian, chrome, and lemon yellows, and also aureolin, although less so, are yet fairly durable, but gamboge and yellow lake are not. Among greens, oxide of chromium undergoes no change, terre verte is practically permanent, and so also is emerald green, but it is blackened by contact with cadmium yellow. Among browns, burnt sienna, raw and burnt umber, cappagh brown, and Caledonian brown do not at all fade; but hardly as much can be said of madder brown, Cologne earth, and Vandyke brown, although these are fairly durable. Asphaltum or bitumen has a tendency to move on the canvas unless very carefully prepared, and its rich brown colour is not altogether permanent. Lampblack, ivory black, and charcoal black are quite durable, so also are flake white, zinc white, and baryta white. It is generally the case that a colour produced by a mixture of permanent pigments is also permanent, and it may be added here that flake white (white lead), so much used to mix with other colours for light tints, is liable to discolour when exposed to sulphuretted hydrogen (an occasional impurity in coal-gas), and this colour has also a tendency to tarnish when kept in the dark.

The above remarks on colours made up with oil apply equally to water-colour pigments, with a few exceptions. These are vermilion, especially if artificial, Naples yellow, chrome yellow, and madder brown, the permanency of which cannot be relied upon in Water-colours, under which head some further remarks on this subject will be found.

Fuller information about the pigments named above, as well as others, will be found under the heads Asphalt, Black, Blue, Green Pigments, Lakes, Ochres, Purple Colours, Red Colours, and Yellow Colours. The oils and varnishes used as media for pigments, as well as the nature of the prepared canvas or paper used for painting upon, have all a bearing on the preservation of the colours of a picture. See the *Chemistry of Paints and Painting*, by A. H. Church (1890). The history of the introduction of the principal pigments is given at Painting, Vol. VII. p. 702.

Pigments of Animals. That animals are often brightly coloured is evident. Some of the simplest, such as many Radiolarians, are brilliant; sponges are often suffused with pigment; sea-anemones and corals are justly compared to flowers; many marine worms have an iridescent sheen; the Echinoderms are almost always bright; many crustaceans have a jewel-like radiance; myriads of insects are lustrous; the shells of molluscs are rich in beauty; the fishes gleam in silver and gold and many hues; even the amphibians are sometimes gaily pigmented; some lizards and snakes seem like flashes of colour; birds are often brilliantly decorated; and mammals have a subdued but often rich colouring in their fur. But all the colours of animals are not due to pigments, for air-spaces in hairs and feathers make these structures white; crystals of guanin or lime often produce a silvery glimmer; striation and other physical peculiarities of the surface cause iridescence.

The most important Pigments.—(*a*) Pigments called lipochromes are among the commonest, occurring in the skin of crustaceans, molluscs, fishes, and birds, in yolk of egg, in the vascular fluid of invertebrates, and also in flowers. Carotin, lutein, tetronerythrin, yellowish chlorophanes, and rosy rhodophanes are representative examples. The reddish pigment conspicuous on many crustaceans is probably a rhodophane, and into this or analogous lipochromes the bluish and greenish pigments of some lobsters and crabs seem to be converted when the animals are boiled or preserved in alcohol or treated with acids. (*b*) Melanoid and lipochromoid pigments, usually of a dark colour, sometimes derivable from (*a*) or from the substances which give rise to (*a*), occur, for instance, in Gorgonid corals, shells of molluscs, the ink of Sepia, the eyes of vertebrates, and in tumours. (*c*) Uranidin pigments of a yellow colour, becoming brown or dark-violet in association with ferments, occur in Tunicates, Gastropods, insects, and sponges. (*d*) Hæmoglobin and its derivatives, of pre-eminent importance in connection with respiration, are of wide occurrence. Hæmoglobin itself, the red pigment of the blood which enters easily into a loose union with oxygen, is present in all vertebrates except Tunicates, Amphioxus, and two or three (perhaps anæmic) fishes. Among invertebrates it is known in some molluscs, crustaceans, and 'worms,' in the larva of the dipterous insect Chironomus, and in a few Echinoderms. It is not known to occur in any cœlenterate, sponge, protozoon, or plant. Among the important derivates of hæmoglobin are hæmatoporphyrin in the oviduct of birds, giving some of the colour to the egg-shells, bilirubin in the bile, and biliverdin, another bile-pigment, which also occurs in the shells of some snails. As respiratory pigments ought also to be reckoned the hæmocyanin in the vascular fluid of molluscs and Arthropods, various violet and purple floridine pigments from sponges and from the Polyzoon Bugula, and, according to Sorby, the aphidein of aphides. (*e*) Chlorophyll, the almost constant colouring matter of plants, apparently consisting of a mixture of two pigments (chlorophyll-green and chlorophyll-yellow), perhaps occurs in a few animals, green infusorians, the fresh-water sponge, the green hydra. It is not quite certain, however, that the green pigment of these animals is identical with that of plant-green; it may be a closely analogous substance. Chlorophyll-yellow is a lipochrome and occurs in many animals. (*f*) Indigo pigments are said to occur in the urine of mammals, and in the purple secretion of the whelk Purpura. The secretion of Murex, which turns violet in the light, has not been sufficiently investigated.

Physiology of Pigments.—Within recent years many of the pigments of animals have been analysed, and some facts about their relationships have been discovered. But in regard to the conditions of their formation, and the purposes which they may serve within the body, comparatively little is known. As the soil may influence the colouring of flowers, so the food given to birds may affect the brightness of their plumage. There are several facts of a similar nature. Cold seems to be one of the conditions which induce a winter change of colouring in a few birds and mammals, and in the butterflies *Arasehnia levana* and *A. prorsa*, which seem to be diversely coloured varieties of one species. Light, which is so important a factor in the development of chlorophyll in plants, has also an influence on the pigmentation of animals. Thus, apart from the effects of keeping animals in darkness, it has been shown by E. B.

Poulton that surrounding colours modify those of some caterpillars, and J. T. Cunningham has demonstrated that young flat-fishes when illumined on the normally shaded and unpigmented side develop pigment-cells on that surface.

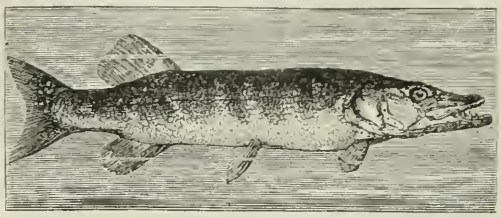
But in regard to the internal conditions of the formation of pigment we are more ignorant. Their relation to the general metabolism of the body is one of the unsolved problems of comparative physiology. Some seem to be of the nature of waste-products, a few are perhaps reserve substances, many may be called by-products of metabolism. On the other hand it is well known that many pigments are auxiliary to some of the important functions of the body. Thus, hæmoglobin and analogous substances are important in connection with respiration; the chlorophyll of plants is essentially associated with assimilation; the pigments found in the eyes of animals seem to aid in the visual function.

External Utility of Colouring.—In many different ways the colouring of animals is of importance to their well-being in the struggle for existence. Thus, the green insects and reptiles which live in the grass or on trees, the sandy-coloured beasts which are hardly to be detected against a background of similar colour, the white animals which are almost invisible among the snow illustrate protective colouring. This colour-resemblance between animals and their surroundings is sometimes marvellously exact, and doubtless of great advantage. Moreover, not a few animals, among crustaceans, fishes, amphibians, and reptiles, have the power of changing their colour, for the pigment-cells expand or contract under nervous stimulus, and this is in some cases advantageously protective. The conspicuous colours of some unpalatable or noxious animals may be an expression of their constitution, while, according to a theory of another order, they warn off possible molesters. It may also be that colours are sometimes useful in assisting mutual recognition between individuals, or in indicating attitudes and movements. Finally, in many animals the sexes differ markedly in colour, the males being almost always brighter than their mates. According to some, this depends on the constitutional peculiarities of maleness and femaleness, while Darwin has emphasised that the brightness of males has been enhanced by the selective taste of the females, and Wallace has urged that natural selection has retarded female butterflies and birds from attaining a brightness which would expose them during the weakness or preoccupation of the reproductive period to the hungry eyes of their enemies. But our recognition of the way in which variations of colouring are fostered or eliminated in the course of natural selection must not lead us to forget the primary problems of the origin of the pigments, and of the physiological conditions which determine their distribution.

See BILE, BLOOD, CATERPILLARS, CHLOROPHYLL, ENVIRONMENT, FLOWER, MIMICRY, SEX, and SEXUAL SELECTION. C. Fr. W. Krukenberg in his *Grundzüge einer vergleichenden Physiologie der Farbstoffe und der Farben* (Heidelberg, 1884) has given an admirable account of the animal pigments, with a bibliography of important researches, such as those of Kühne, MacMunn, Moseley, and Sorby. See also M'Kendrick, *Text-book of Physiology* (1888); Halliburton, *Physiological and Pathological Chemistry* (1891). For the relation between colour and the external conditions of life, see Semper's *Animal Life* (Inter. Sc. Series, 1881); and for the importance of colour in the external life of animals, Poulton's *Colours of Animals* (Inter. Sc. Series, 1890).

Pigott, RICHARD. See PARNELL.

Pike (*Esox lucius*), a well-known fresh-water fish abundant in the temperate parts of Europe, Asia, and America. The body is long and covered with small cycloid scales; the dorsal fin is near the tail; the mouth is large, with strong, sharp teeth; the lips have no barbels; the stomach is without the usual pyloric appendages; the open (physostomatous) air-bladder is simple; the gill-aperture is very wide. The fish is olive-gray above, silvery white on the belly, and is mottled with pale spots; in length it may measure from 2 to 4 feet; and it may attain a weight of 10 to 20 lb., or in rare



Pike (*Esox lucius*).

cases, it is said, about 60. The genus includes besides four or five other species, notably the *Muskallunge* of the North American lakes, a 'grand game fish,' often 6 feet long, in habit a dauntless marauder. Another of smaller size (*Esox reticulatus*) is the common *Pickerel* of the eastern states. All three are valuable food-fishes.

The common pike or *Jack* (Scotch *Gedd*) is said to spawn when three years old. The ova are usually laid in March, but the spawning is protracted. There is great mortality among the young, which take about a week to hatch. Growth is at first rapid, and continues more slowly for years. The longevity of the fish is great, but the records of pike which have attained to 250 years are as unsatisfactory as the evidence for longevity usually is. There is no doubt, however, that they may outlive their keepers; and it is also true that they sometimes venture ashore, and that they sometimes lie in a torpid slumber in the pools. But the most characteristic quality of pikes is voracity. Feeding for the most part on frogs and small fishes, they are often prompted by hunger to bid for higher game, such as ducks, geese, water-hens, and water-rats. Thoreau describes the pike as the 'swiftest, coarsest, and most ravenous of fishes, which Josselyn calls the river-wolf. It is a solemn, stately, ruminant fish, lurking under the shadow of a lily-pad at noon, with still, circumspect, voracious eyes; motionless as a jewel set in water, or moving slowly along to take up its position; darting from time to time at such unlucky fish or frog or insect as comes within its range, and swallowing it at a gulp. Sometimes a striped snake, bound for greener meadows across the stream, ends its undulatory progress in the same receptacle.' The Bony Pike (Lepidosteus) is a Ganoid, and the name is sometimes applied to the marine Gar-fish (Belone) and to some American perches. See BONY PIKE, GAR-PIKE.

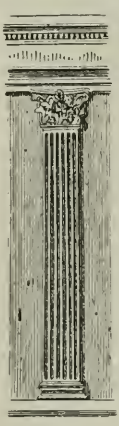
See the articles ANGLING and PISCICULTURE; Pennell's *Book of the Pike* (3d ed. 1884); and Bickerdyke's *Angling for Pike* (1888).

Pike, a word loosely used for almost any kind of lance or Spear (q.v.), whether larger or smaller headed, as used by infantry troops, and now superseded by the bayonet. The naval boarding-pike is a lance about the length of a man. The short pike, called *half-pike* or *spontoon*, long carried by some classes of infantry officers in most European armies, was a kind of Halbert (q.v.) with a smaller but ornamented head, and was rather an emblem of dignity than a fighting weapon. In 1804, when a French invasion was threatened, pikes were distributed by government through the country; and the secret manufacture of iron pike-heads was one of

the most disquieting features of the Radical reform agitation in 1819 and during the Chartist troubles.

Pike's Peak, a peak of the Rocky Mountains, in Colorado, 65 miles S. of Denver, discovered by Captain Pike, U.S.A., in 1806. It is situated in 38° 50′ N. lat. and 105° 2′ W. long., and rises to a height of 14,134 feet. On its summit is one of the highest meteorological stations in the world; while at the base, at Colorado Springs, there is a low-level station. A railway to the top, 9 miles long (4½ miles of curves), with a maximum gradient of 1 in 4, has been constructed.

Pilaster, in Classical Architecture, a square pillar, sometimes standing free, but usually attached to a wall, from which it projects $\frac{1}{5}$th, $\frac{1}{4}$th, or other definite proportion of its breadth. Greek pilasters, or antæ, were of the same breadth from top to bottom, and had different capitals and bases from those of the orders with which they were associated. The Romans gave them a taper like the columns, and the same capitals and bases.



Pilaster.

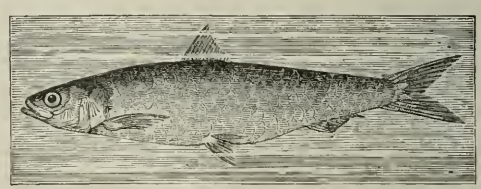
Pilate, PONTIUS, the fifth Roman procurator of Judæa and Samaria, from 26 to 36 A.D. He was personally convinced of the innocence of Jesus, and tried to save him, yet sent him to be crucified to appease the raving mob of Jerusalem, washing his hands before the people to show that he took no responsibility for his death. His rapacity and cruelties caused many outbreaks, which were sternly suppressed, and at length culminated in the murder of a number of Samaritans on Mount Gerizim, which caused such loud complaints that Vitellius sent him to Rome to answer to Cæsar (36 A.D.). Eusebius tells us that Pilate made away with himself; others say that he was banished to Vienna Allobrogum (*Vienne*), or beheaded under Nero. In the Eastern Church there is a persistent tradition that he eventually embraced Christianity like his wife, and indeed in the Ethiopic Church Pilate is commemorated as a saint, his day falling on June 25. Pilate is said by Justin Martyr, Tertullian, and Eusebius to have forwarded to Tiberius for his own justification an account of the judgment of Jesus, but the so-called *Report*, and *Acts of Pilate*, as well as the two letters of Pilate to Tiberius, have no claim to authenticity.

Many legends have clustered round the sinister figure of Pontius Pilate. One relates how his body was flung into the Tiber, and caused the river to overflow, and how it was next thrown into the Rhone near Vienne, but (according to the latest form of the mediæval legend) again caused so great a storm that it was carried to Mount Pilatus near Lucerne, and there sunk securely in the deep pool on its top. But here again it made storms arise, and every year to this day on Good Friday the devil lifts him out of the pool and sets him on a judgment-seat, where he washes his hands anew.—Pilate's wife, traditionally called Procla or Claudia Procula, from her solemn warning to her husband against putting Jesus to death, has been regarded as a Christian by Origen, Chrysostom, and Hilary. In the Greek Church she is a saint, her day falling on October 27. See R. A. Lipsius, *Die Pilatus-Acten* (Kiel, 1871).

Pilatus, MOUNT (Lat. *Mons Pileatus*, 'the hooded peak,' from its top being frequently enveloped in cloud; the legends connecting Pilate (q.v.) with the place have presumably grown out of the altered name), an isolated mountain at the western end of the Lake of Lucerne, rising opposite the Rigi. The lower half is clothed with wood and meadow, where in summer over 4000 head of cattle are pastured; the upper portion is a mass of bare and jagged peaks, rising in the Tomlishorn to 6998 feet. Below the summit lies Lake Pilatus (see preceding article). On two of the peaks there are hotels; and since 1889 there has been a tooth-and-rack railway from Alpnach to the top, whence there is a splendid view of the Bernese Alps. In 1891 a steel tower was undertaken, to be 300 feet in diameter at its base and 840 feet high, and so pierce any enveloping cloud.

Pilau, or PILLAF, a dish common in Turkey, Egypt, Syria, and India, consists generally of rice, thoroughly boiled, drained, and gently stirred with butter, pepper, and finely-chopped onions. For the tables of the wealthy, fowls, lamb, mutton, shreds of ham or bacon, variously cooked, but always much boiled or roasted, are placed on the top of the rice, and served up with it.

Pilchard (*Clupea pilchardus*, or *Alosa sardina*), an important fish of the family Clupeidæ. The pilchard is nearly equal in size to the herring, but rather thicker, and the lines of the back and belly are straighter; the scales are also larger and fewer; and the dorsal fin is rather farther forward. The mouth is small, and in the adult fish destitute of teeth; the under-jaw is longer than the upper. The upper part of the body is bluish green, the sides and belly silvery white, the cheeks and gill-covers tinged with golden yellow, and marked with radiating striæ, the dorsal fin and tail dusky. The pilchard is an inhabitant of more southern seas than



Pilchard (*Clupea pilchardus*).

the herring. In British seas it is abundant off the coasts of Devon and Cornwall, and the south and south-west coasts of Ireland; towards the east end of the English Channel it becomes scarce, and off the more northern coasts of the British Isles it is only taken occasionally in small numbers. It extends in abundance throughout the Bay of Biscay, along the west coast of Portugal, and the shores of the Mediterranean; its southern limit is Madeira. In France this fish is known as *la sardine*. It is true that the sardines in oil imported into Great Britain are smaller than the majority of English pilchards, but they are of the same species. The English pilchard is usually about 10 inches long. The French sardine is said by Moreau to be from 12 to 20 cm. in length—i.e. 5 to 8 inches—sometimes reaching 25 cm. or 10 inches. The fish used for preserving in France are certainly young and not full grown. Pilchards are now prepared in oil in the same way as French sardines, at Mevagissey in Cornwall, and have an extensive sale; so are Sprats (q.v.) at Deal. The fish are captured both by drift-nets and seines; the former method is pursued along the south coast of Devon and Cornwall, while the principal seat of the seine-fishery is St Ives. The drift-net fishing begins in August and continues with fluctuations until the following April, the largest number being landed in November, December, and January. The drift-nets are each 120 yards in length, and a fleet consists of twelve to fifteen, fastened together, and extending to nearly a mile. They

are 6 fathoms in depth, and the meshes are usually thirty-six to thirty-eight to the yard. The mesh of the nets used on the French coast is much smaller, not exceeding $\frac{5}{8}$ths of an inch square. The smallest seines used at St Ives are 160 fathoms long, with a depth of 8 fathoms at the centre, and 6 fathoms at the wings; the meshes are $\frac{3}{4}$ths of an inch square. In the seine the fish are not meshed: if they were they would cause the net to sink. There are only six 'stations' or places fit for hauling the seine at St Ives, and over two hundred seines. The nets are therefore divided into groups, and each net has to await its turn at the station to which it belongs. The regulations of the fishery are contained in the Sea-fisheries Act, 1868, 31 and 32 Viet. chap. 45, sect. 68. The seine-fishery is carried on principally between August and Christmas. Most of the pilchards landed in Devon and Cornwall are salted for the Mediterranean market, especially Italy. They were formerly cured dry, the fish being piled in heaps with salt on a floor, and the brine and oil draining away from them constantly. After remaining thus about a month the fish were sifted from the salt, washed, packed in barrels, and subjected to pressure which forced more oil from them. But at present the salting is carried out in watertight vats, so that the brine formed rises over the fish, and they are kept steeped in the liquid for several weeks or months. They are then washed, packed, and pressed as before, the oil being collected and sold principally for the use of leather-dressers. This wet process produces much cleaner and brighter-looking fish than the old dry process. Twelve thousand to fifteen thousand hogsheads of these cured pilchards are annually exported to the Mediterranean, each hogshead containing from 2500 to 3000 fish, and weighing 476 lb. gross. A large number of pilchards are also used as bait for long-line and hand-line fishing, and a good many are eaten fresh locally or in distant markets.

Unlike herrings, the pilchards which are captured are not in breeding condition, but are fat, with small reproductive organs. In fact the habits of the pilchard are the direct converse of those of the herring. The pilchard is found feeding near shore in more or less abundance for nine months of the year, but in June, July, and August, when as a rule none are being caught near shore, spawning pilchards are found at some distance, 10 to 50 miles or more, from the land. At this season a few are occasionally taken in mackerel nets, in which the largest ones are meshed in consequence of their swollen condition. The ova, unlike those of the herring, are quite transparent, and buoyant like those of the cod and mackerel; they pass through their development while suspended separately in the sea-water. Like the herring, the pilchard feeds upon minute crustacea and other animals, some adult, some larval, which swarm in the sea.

The principal foreign fisheries are at Concarneau and other places in the Bay of Biscay, the mouth of the Tagus in Portugal, and Marseilles, Nice, and other ports in the Mediterranean. In Scotland the pilchard is known as the *Gypsy Herring*, *Garvie Herring* (the sprat being *Garvie*), or *Crue Herring*.

Pilcomayo, a river of South America, which takes its rise in two branches in the Bolivian Andes, in the department of Potosí, flows in a very winding course south-east through the Gran Chaco, separating Paraguay and Argentina, and finally joins the Rio Paraguay a little below Asuncion. Its length is said to be 1700 miles, but this is mere guess-work, as no one yet has explored its entire course, and what is known of it is too tortuous for a basis on which to estimate the whole. The volume of water brought down is comparatively insignificant, much being spent in lagunes on its way; at the mouth there is scarcely any perceptible current, and the breadth is not 60 yards, while within the first 200 miles it narrows more than once to less than 20 yards, and moreover divides into branches, among some of which explorers, like Captain Page, have lost their way. There have been many attempts, all fruitless, made to open the river route between Argentina and Bolivia; since 1556 a score of expeditions have been sent out, and many of the explorers have perished. Some have obtained 6-feet soundings for 255 miles from the mouth, but then came rapids, where the river was not more than 2 feet deep; the upper stream, too, is rendered impassable by numerous rapids, and long canals would be required to open the river to navigation. In its upper course its sands are auriferous and the banks fertile; lower down the valley is swampy. The river's water is rendered like brine by the great salt lakes of the Chaco—in which part the river is buried for hundreds of leagues in a great forest of fan-palms.

Piles are usually squared logs of wood used in engineering operations, such as dams, bridges, and roads (see COFFERDAM, &c.) They are sharpened at the point, and, if necessary, protected with iron points, to enable them to cut through the strata they encounter as they are driven into the ground. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings, roads, &c. may be placed. Cast-iron is also used for piles, which are cast hollow. Common piles are driven in by machines called *pile-drivers*. In these a heavy weight (or monkey) is raised to a considerable height between two guides, and then let fall on the head of the pile. The application of steam to these drivers has made them very powerful engines—Nasmyth's steam-hammer being a well-known instance. See also LAKE-DWELLINGS.

Piles, or HÆMORRHOIDS, are small tumours situated either within or on the verge of the anus. The first step in their development is the dilatation of one or more veins in this region. They consist of folds of skin or mucous membrane, with the subjacent tissues in an inflamed, infiltrated, or permanently thickened condition, and usually contain enlarged veins, though these sometimes become obliterated. There are several varieties of these tumours. Sometimes the pile is mainly composed of a little knot of varicose veins; in this case it is readily emptied by pressure of the fluid blood contained in it, which, however, returns when the pressure is removed. Sometimes the blood coagulates, either in a dilated vein, or, if this has given way, around it, forming a solid tumour surrounded by tissues thickened in consequence of inflammation; or the tumour may consist of a kind of erectile tissue formed by an abnormal condition of the vessels of the mucous membrane; this variety is especially liable to bleed. These tumours are divided into *bleeding* and *blind* piles, according as they are or are not accompanied with hæmorrhage; and into *internal* and *external* piles, according as they are within or without the sphincter muscle of the anus.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a feeling of heat, fullness, and dull pain about the lower part of the bowel, becomes conscious of a sensation as if there were a foreign body in the anus, and on examination after an evacuation discovers a small tumour, usually about the size of a grape, which either remains outside or is retracted, according as it originated without or within the sphincter. This tumour gradually increases, and others form around it, until a mass at length results as large as a pigeon's egg, or larger. In its ordinary *indolent* state the tumour

has little sensibility, and occasions comparatively little annoyance; but when it is *inflamed* (from strangulation by the sphincter muscle, or from any other cause) it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes of the bladder also) difficult and painful. In women an inflamed pile may cause pain in the back, irritation of the womb, with mucous discharge, and many other anomalous symptoms. In severe cases the patient can neither stand nor sit with comfort, and only finds relief in the horizontal position. In internal piles the most important symptom, sometimes the first to be noticed, is hæmorrhage, which may be so profuse or so often repeated as to threaten the patient's life.

Piles may be caused by any circumstances which cause congestion in the lower bowel, such as luxurious and sedentary habits of life, pregnancy, and such diseases of the liver as tend to check the return of blood from the veins of the rectum. Moreover, anything that causes irritation of the rectum, such as excessive use of purgatives, dysentery, inflammation of the prostate gland, &c., may cause piles. But of all causes constipation is probably the most frequent; it operates in producing them partly by the pressure of the accumulated and hardened fæces upon the veins carrying the blood away from the rectum, and partly by the straining and irritation such fæces occasion during their evacuation.

In the treatment of piles it is expedient to relieve the congested state of the lower bowel by one or two doses of sulphate of magnesia, and a cooling vegetable diet, after which the continued use of mild laxatives should be resorted to. A teaspoonful of an electuary, consisting of an ounce of confection of senna, half an ounce of cream of tartar, and half an ounce of sulphur, if taken in the middle of the day, usually acts gently about bedtime, which is far the best time for the bowels of patients of this kind to act, as the parts irritated by the passage of the evacuation become quieted during the night. In long-standing cases, in which there is general relaxation of the mucous membrane, the confection of pepper in doses of a drachm may be given thrice daily with advantage, or a scruple of common pitch may be taken at bedtime in the form of pills or in capsules. Preparations of witch-hazel (*Hamamelis virginica*) are also useful. Amongst the milder forms of local treatment must be mentioned (1) the injection of the rectum with cold water both before and after the motion; (2) washing the anus with yellow soap and water after each evacuation—this should never be omitted by any one who suffers from piles; (3) the application of gall ointment or of other astringents; and (4) the injection of astringent lotions, as, for instance, of sulphate of iron, in the proportion of a grain to an ounce of water. When the piles are inflamed, leeches to the anus (but not applied directly to the tumours) are sometimes required; but the inflammation generally subsides under the influence of rest in the horizontal position, fomentations, poultices, and low diet. In severe and prolonged cases operative interference becomes necessary. For external piles removal with scissors is usually employed. In certain forms of internal piles the application of caustics, especially nitric acid, sometimes suffices. Where their removal is required it may be effected either by ligature or by cauterisation.

The treatment of the hæmorrhage that frequently accompanies piles requires a few words. If the bleeding is moderate in quantity, and has continued for some time without inducing weakness or any other bad symptom, it is not expedient to interfere with it. When, however, it obviously requires checking, the effect of cold water injected into the rectum, as already recommended, should be tried, and, in case of its failing, astringent injections should be had recourse to. At the same time the patient should remain in the horizontal position, and take the medicines usually prescribed for internal hæmorrhage, amongst which may be especially mentioned witch-hazel, oil of turpentine, in doses of twenty drops three or four times a day, or ergot of rye in divided doses to the extent of a drachm daily. In rare cases it is necessary to tie a vessel, or to touch it with a red-hot wire (through the speculum), or to plug the anus.

Pileus (Lat., 'a hat'), the upper expanded portion of many Fungi (q.v.).

Pilewort. See Ranunculus.

Pilgrim (Ital. *pellegrino*, Lat. *peregrinus*, 'a visitor of foreign lands'). A pilgrim is one who visits, with religious intent, some place reputed to possess especial holiness. The early Christians, like the Jews and the pagan Gentiles, regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the Passion of our Lord at Jerusalem. St Jerome refers the practice of visiting Jerusalem to the discovery of the Holy Cross by St Helena. He himself was a zealous pilgrim; and throughout the 4th, 5th, and 6th centuries pilgrims habitually undertook the long and perilous journey to the Holy Land from almost every part of the West. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by St Jerome. St Basil speaks in the same terms of the tomb of the Forty Martyrs; and the historian Theodoret tells of not only visiting such sanctuaries, but of hanging up therein, as offerings, gold and silver ornaments, and even models of hands, feet, eyes, &c., in commemoration of the cures of diseases supernaturally obtained as the fruit of these pious visits. The Pilgrimage, however, pre-eminently so called, was that of the Holy Land; and, even after Jerusalem had been occupied by the Saracens, the liberty of pilgrimage, on payment of a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage that the well-known Military Orders had their origin. The Crusades may be regarded as a pilgrimage on a great scale; the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the Crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the West were, in Italy—Rome, Loretto (q.v.), Assisi; in Spain—Compostella, Guadalupe, Montserrat; in France—Fourvières at Lyons (q.v.), St Denis; in Germany—Maria Zell, Cologne, Trèves; in Switzerland—Einsiedeln; in England—Walsingham, Canterbury, and many others of minor note; in Scotland, Whithorn, Whitekirk (near North Berwick), Loretto (near Musselburgh), Scone, Dundee, Paisley, and Melrose; in Ireland, Lough Derg (q.v.), and many places connected with the life or death of the early Irish saints. The pilgrim commonly bound himself only by a temporary vow (differing in this from the palmer), which terminated with the actual visit to the place of pilgrimage, or at least with the return home, and by which he was bound for the time to chastity and to certain other ascetic observances. The costume consisted of a black or gray gabardine, girt with a cincture, from which a shell and scrip were suspended, a broad hat, ornamented with

scallop-shells, and a long staff. Many abuses arose out of these pilgrimages, the popular notions regarding which may be gathered—although, probably, with a dash of caricature—from Chaucer's *Canterbury Tales*, and from Erasmus' account of the pilgrimage to Walsingham (*Peregrinatio religionis ergo*). Pilgrimages have gone much into disuse in France since the Revolution. In late years, however, pilgrims have resorted in large numbers, not only to the ancient sanctuaries of Fourvières, Puy, &c., but also to La Salette, Paray-le-Monial, and since 1858 to Lourdes. There were special pilgrimages by English Catholics to Pontigny (1874), Holy Island (1887), and Iona (1888). Knock (q.v.) has become since 1880 a resort of Irish Catholics. Positivists also visit the places connected with the lives of selected great men. Benares is one of the great places of pilgrimage for Hindus; and the Hajj to Mecca is the goal of every true Moslem's ambition. See Jusserand's *English Wayfaring Life in the Middle Ages* (Eng. trans. 1888).

Pilgrimage of Grace, the name given to a rising of the rural population in the counties of Lincolnshire and Yorkshire in the end of 1536. When the commissioners charged with the suppression of the minor monasteries arrived in Lincolnshire, reports were spread abroad among the people that all the church jewels and plate were to be taken away, that most of the churches were to be pulled down, that new taxes were to be levied, and that the rights of the commons were in other ways to be vexatiously interfered with. The rising began at Louth on 1st October; 20,000 men soon gathered at Lincoln, under the leadership of Dr Mackerel, Abbot of Barlings, a shoemaker named Melton, better known as Captain Cobbler, and some of the dispossessed monks and gentry. But the approach of the Duke of Suffolk from the south, and a proclamation by the Earl of Shrewsbury, who was drawing near from the west, stating that what had been done was with the consent of parliament, and promising a free pardon to the rebels, caused them to disband and go away home (October 13). In the meantime a similar rising for precisely similar causes had taken place in Yorkshire; it began on 9th October in the East Riding, the chief leader in the movement being a lawyer named Robert Aske. The rebels, 40,000 in number, took York and Pontefract, capturing in this last town Lord Darcy and the Archbishop of York (not unwilling to be captured). The king sent against them the Earl of Shrewsbury and the Duke of Norfolk, and on the reading of a similar proclamation to that in Lincolnshire they dispersed to their homes. In the following year Aske, Sir Robert Constable (who had been associated with Aske in the leadership), Lord Hussey (suspected of complicity in the Lincolnshire movement), Mackerel, and others, about twenty in all, were executed. See Gairdner's Preface to *Calendar of State Papers, Foreign and Domestic: Henry VIII.*, vol. xi. (1888).

Pilgrim Fathers, the first English colony which settled in Massachusetts (q.v.). The company, numbering one hundred men, women, and children, set sail from Plymouth in the *Mayflower* on 6th September 1620, bound for the banks of the Hudson; but after a long and stormy voyage they landed (21st Dec.) on the bleak shores of Cape Cod, and founded the settlement of Plymouth (q.v.).

See Deverell's *Pilgrims and the Anglican Church* (1887); Goodwin's *Pilgrim Republic* (Boston, 1888); the *History of the Plimouth Plantation*, reproduced from the MS.—itself restored to the U.S. in 1897—of William Bradford, the pilgrim who became governor of the colony; and books by John Brown (1895) and E. Arber (1897).

Pilibhit, a town in the North-west Provinces of India, 30 miles NE. of Bareilly; pop. 33,799.

Pillar, a detached support like a column; but its section may be of any shape, whereas the column is always round. Pillars have been used in all styles of architecture, and their forms and ornaments are usually amongst the most characteristic features of the style. The Greek and Roman pillars (or columns) are the distinguishing elements in the various orders. In Gothic architecture, also, the pillars or piers are of different forms at the various epochs of that style. In the Norman period we have plain massive pillars, square, circular, and octagonal, frequently ornamented with zigzag ornaments, spiral bands, &c. on the surface (fig. 1). As vaulting progressed, the system of breaking the plain surface of the pier, and giving to each portion of the vaulting a separate little column or shaft to support it, was introduced. This was done either by attaching shafts to the pillars, or by cutting nooks in the pillars and setting little shafts in them, thus: *a*, *b*, fig. 2. In the Early Pointed style a plain circular or octagonal pillar, with a number of small shafts attached around it, is a favourite arrangement, thus: *c*, *d*, fig. 2. In this style the attached shafts are very frequently banded to the main pillar at different heights, and they are sometimes made of a finer material, such as Purbeck marble. In the Decorated style the pillar is of a lozenge form, and not so much ornamented with detached shafts as with mouldings; plain, circular, or octagonal pillars, however, are used in this, as in all the styles. The mouldings and shafts

Fig. 1.
Norman Clustered Pillar.

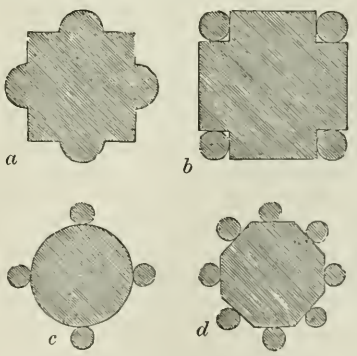


Fig. 2.

are usually filleted; and some of the mouldings run up into the arch without any cap. In Perpendicular the same idea is further carried out; the mouldings become thinner, and are more frequently run up into the arch without caps. See FLAMBOYANT.

Pillar-saints, an English rendering of the Greek *stylitai*, the name of a class of hermit-ascetics, chiefly Syrian, who crucified the flesh by living on the summit of pillars in the open air. The most noted was Simeon called Stylites (q.v.).

Pillau, a Prussian town and fortress of the third rank on a spit of land at the entrance of the Frisches Haff, 30 miles W. of Königsberg by rail. Pop. 3434.

Pillnitz, the ordinary summer residence of the royal family of Saxony, in a beautiful situation on the Elbe, 5 miles SE. of Dresden. The palace embraces three main buildings or 'castles,' and is surrounded with beautiful parks and gardens. Here, in August 1791, the Declaration of Pillnitz was framed, according to which Austria and Prussia agreed to take common action on behalf of the royal family of France against the Republicans.

Pillory, an engine for the public punishment of criminals, disused in Britain since 1837, but previous to that time commonly employed, as it also was in France and Germany. It consisted of a stout plank fixed like a signboard on the top of a pole, the pole being supported on a wooden platform elevated above the ground. Above, and parallel to this plank, another of like dimensions was placed in a similar position with respect to the pole, and fixed to the former by a hinge, being thus capable of being moved upwards from it, or closed upon it, when necessary. A large circular hole was cut, with its centre in the line of junction of the two planks, and two corresponding holes of smaller size were formed, one on each side of it; the large hole was for receiving the neck, and the two smaller the wrists. When a criminal was to be placed in the pillory he was made to mount and stand upon the platform; the upper of the two hinged planks was raised to allow the culprit's neck and wrists to be inserted in their proper grooves, and then brought down into its place, and fastened by a padlock, or in some other way. The pillory seems to have existed in England before the Conquest, in the form of the *stretch-neck* (an instrument by which the neck only was confined), and was originally intended, according to the 'Statute of the Pillory' (51 Hen. III. chap. 6), for persons guilty of forestalling and regrating, using deceitful weights and measures, perjury, &c. Its use was exclusively confined to this class of offenders till 1637, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favourite mode of punishing libellers against the government, and many eminent men were accordingly from this time pilloried, among them Leighton, Lilburn and Warton the printers, Prynne, Dr Bastwick, and Daniel Defoe. These sufferers were popular favourites, and the encouragement, applause, and sympathy of the crowd around converted the intended punishment into a triumph; but such men as Titus Oates, and the class of offenders including perjurers, swindlers, polygamists, &c., who were objects of popular hatred and disgust, were pelted with rotten eggs, garbage, mud, sometimes even with more dangerous missiles. In 1797 the preacher Thomas Evans was pilloried for singing a seditious Welsh song; so too, in May 1812 was Eaton, the publisher of Paine's *Age of Reason;* and in 1814 the celebrated naval hero Lord Cochrane, afterwards Earl of Dundonald, was sentenced to stand an hour in the pillory, but in the latter case the government did not dare to carry the sentence into effect. The punishment was abolished for all offences save perjury in 1815; and the perjurer Peter James Bossy was the last to stand in the London pillory, in the Old Bailey, for one hour, on 22d June 1830. In France the pillory was anciently called *pilori* (a word of unknown origin), and in recent times *carcan*, from the iron collar by which the criminal's neck was attached to the post; and even so late as 1840 a woman who had poisoned her husband was at least sentenced to the pillory at Tulle as part of her punishment.

Defoe's occupancy of the pillory on the 29th, 30th, and 31st July 1703 was memorable in many ways, and helped to deprive the pillory of its terrors. He ingeniously took the opportunity of publishing on the first day of his appearance there his vigorous *Hymn to the Pillory;* the crowd was on his side, and instead of pelting him with unpleasantnesses, crowned the pillory with flowers and drank the martyr's health. 'Dauntless on high stood unabashed Defoe,' like a new Simeon Stylites, and his temper was apparently infectious.

See Douce's *Illustrations of Shakespeare,* Griffith's *Chronicles of Newgate,* Andrews' *Punishments in the Olden Times,* and Jewitt in the *Reliquary* for April 1861. See also Jougs, Cang, Stocks, and Stool of Repentance.

Pills are the most generally convenient and popular of all forms of medicine. They are formed from masses of a consistence sufficient to preserve the globular shape, and yet not so hard as to be of too difficult solution in the stomach and intestines. This form is especially suitable for drugs which operate in small doses, as aloes, colocynth, &c., while the disagreeable taste is always less than when the drug is given in solution. It is also useful where it is desired that the drug shall not dissolve in the stomach or upper intestines, but shall act only in the lower intestines. In such cases the pills may be coated with keratine, which is only soluble in the lower bowels. Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most substances require the addition of a material termed an excipient for converting it into a pill-mass. The excipients in most common use are bread-crumbs, hard soap, extract of liquorice, mucilage, syrup, treacle, honey, castor-oil, and conserve of roses. From the property of preserving pills for a long time in a properly soft state the most valuable excipient is the conserve of red roses; and, perhaps, next to it treacle is the most valuable excipient, as it does not undergo any change by time, but maintains a proper consistence, and preserves the properties of vegetable powders unimpaired for years. It is common to place pills in some fine powder to prevent them from adhering to each other, and to conceal their taste. For this purpose liquorice powder, wheat-flour, starch, and magnesia are generally used in Britain, and lycopodium on the Continent. Pills retain their moisture and activity far longer in small bottles than in the ordinary pasteboard boxes. The ordinary weight of a pill is five grains; if it much exceeds that weight it is too bulky to swallow conveniently if consisting of vegetable matter. It is very common to meet with patients who express their inability to take this form of medicine. If, however, they practise with a small globular mass towards which they feel no repugnance, as a pellet of bread or a currant, placing it on the back of the tongue and gulping it down with water, they will soon get over the difficulty.

To many people the taste of pills is a great deterrent, and various methods of coating the pills are resorted to for their benefit. Formerly coating with gold or silver leaf or with a little tolu resin dissolved in chloroform were the only methods; but more recently gelatine-coated, sugar-coated, and pearl-coated pills have been prepared in vast quantities and have become very popular. There is, however, always a risk of the deterioration of such pills, owing to the length of time which they may be kept before being sold. See also Quack Medicines.

Pilocarpine. See Jaborandi.

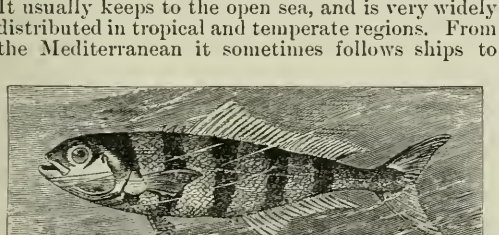
Pilot is a person specially deputed to take charge of a ship while passing through a particular sea, reach, or dangerous channel, or from or into a port. Pilots are of three classes—(1) those licensed to act in districts where the pilotage is compulsory; (2) those licensed to act where the pilotage is not compulsory; (3) unlicensed pilots. British pilots are licensed by the Trinity Houses of London, Hull, Newcastle-on-Tyne, and Leith, and by Pilotage Commissioners in other ports. The British pilotage laws were consolidated by 6 Geo. IV. chap. 125 and in 1853, but extensive changes were made by the Merchant Shipping Act of 1855, part v., and minor changes in 1862, 1872, 1874, and 1889. By the last of these acts the monopoly of employment claimed by licensed pilots has been strengthened. The scale of pilotage fees paid by the ship depends upon the distance piloted and the ship's draught of water. The fees earned are sometimes retained by the pilot earning them, less deductions for collection, superannuation, sick, or widows' funds, and sometimes they are thrown into a joint stock.

In the United States the several states make their own pilotage laws, which generally provide for the appointment of commissioners with power to make all needful rules and regulations.

A British pilot-boat must have conspicuously painted upon it its number, owner's name, and the port to which it belongs, and must show a large flag of two horizontal stripes, the upper white and the lower red. At night a pilot-vessel on its station shows a white light, and in addition shows a flare at intervals not exceeding fifteen minutes. Shipmasters or mates are often licensed to act as pilots for their own vessels.

By British law no owner or master of any ship is answerable to any person whatever for any loss or damage occasioned by the fault of any qualified—i.e. licensed—pilot acting in charge of such ship, within any district where the employment of such pilot is compulsory by law, but this law is not international nor universal. In general, foreign nations are more stringent than Britain in excluding aliens from their pilotage services for military reasons.

Pilot-fish (*Naucrates ductor*), a well-known fish which accompanies sharks and follows ships. It usually keeps to the open sea, and is very widely distributed in tropical and temperate regions. From the Mediterranean it sometimes follows ships to



Pilot-fish (*Naucrates ductor*).

British coasts. In length it is about a foot, in shape like a mackerel, in colour variable, though generally grayish blue with five transverse dark blue bands. The first dorsal fin is represented by a few spines. Its zoological position is beside the horse-mackerels in the family Carangidæ.

Many wonderful stories are told about the pilot-fish, which seems to be the *Pompilus* of the ancients. It is said to guide the shark to its prey—nay, more, to show sailors their desired course. It certainly is a very frequent companion of the shark, especially if that fish be swimming alone, but the precise nature of the association is doubtful. The pilot-fish probably follows the shark as it follows a ship for the sake of scraps of food, and perhaps eats the parasitic crustaceans, &c., with which the skin of the shark is often infested. Moreover, companionship with the shark probably protects the pilot-fish from its enemies.

Piloty, Karl von, head of the new Munich school of painters, was born in that city on 1st October 1826, studied at its academy, and sat at the feet of Schnorr and Schorn and the modern French and Belgian masters of colour. In 1856 he was appointed professor of Painting at the Munich Academy, and in 1874 succeeded Kaulbach as director of the same. He died in his native city on 21st July 1886. All his best pictures belong to the class of historical genre; several of them adorn the sumptuous palaces of art built by the Bavarian kings at their capital, as the Maximilianeum and the New Pinakothek. Piloty was a pronounced realist; he strove to reproduce nature exactly, even to the minutest details, but did not steer clear of the dangers that beset the endeavour to carry out these principles to their most rigorous conclusions. He distorts the relative importance of essentials and subordinate details, and, in spite of his skill as a portraitist, his pictures frequently have a theatrical air. His drawing was strictly objective; but he allowed his personal tastes all the more freedom in the choice of subject and in the employment of colour. Most of his pictures have melancholy subjects and a pathetic effect or sad background; amongst the best of them may be quoted 'Seni beside the Body of Wallenstein,' 'Nero amid the Ruins of Rome,' 'Wallenstein's March upon Eger,' 'Galilei in Prison,' 'Columbus,' 'Death of Cæsar,' 'Announcement of the Sentence of Death to Mary Stuart,' 'Thusnelda in the Triumph of Germanicus,' and 'Death of Alexander the Great.' Piloty was an excellent teacher, his principal endeavour being to develop the individual genius of his pupils, amongst whom were Makart, Defregger, Lenbach, Max, Dietz, and others. See the *Art Journal* for 1865; Mrs Howitt-Watts' *Art-student in Munich* (2d ed. 1879); and Rosenberg, *Die Münchener Malerschule* (1887).

Pilpay. See Bidpai.

Pilsen, the second town of Bohemia, situated in a fertile and beautiful valley, 67 miles by rail SW. of Prague. There are numerous active industries, producing building materials, machinery, metal-work, porcelain, spirits, liqueurs, leather, &c. In the neighbourhood are mines of iron, alum, vitriol, coal, and sulphuric acid. But the town is most widely known from giving its name to the most approved kind of Bohemian beer, which is brewed to the extent of 9 million gallons a year, and (whether made there or elsewhere) is now largely imported into Britain. The town was stormed by Zizka in the Hussite war and by Count Mansfeld in the Thirty Years' War (1618); it was Wallenstein's headquarters in 1633-34. Pop. (1890) 50,221.

Pimento, also called Allspice or Jamaica Pepper, a well-known spice, the dried fruit of *Eugenia Pimenta*, a small West Indian tree chiefly confined to Jamaica, which grows to the height of 20 or 30 feet, and has oblong or oval leaves about 4 inches long, of a deep shining green, and numerous axillary and terminal trichotomous panicles of white flowers, followed by small dark purple berries. The pimento-tree is cultivated in some of the West Indian Islands. It is a very beautiful tree, with straight white trunk and much-branching head; about the month of April it is covered with an exuberance of flowers, which diffuse a rich aromatic odour. The leaves

and bark partake of the aromatic property for which the fruit is valued. The fruit, when ripe, is filled with a sweet pulp, and the aromatic property which so strongly characterises it in an unripe state has in a great measure disappeared. The gathering of the berries, therefore, takes place as soon as they have reached their full size, which is about that of peppercorns. They are gathered by the hand, and dried in the sun on terraced floors, during which process great care is taken, by turning and winnowing, to prevent them from being injured by moisture. Their colour changes in drying from green to reddish brown. When dry they are packed in bags for the market. Some planters kiln-dry them. The name *Allspice* was given to pimento from a supposed resemblance in flavour to a mixture of cinnamon, nutmeg, and cloves. Pimento is much employed in cookery, and is also used in medicine as a carminative and stimulant to prevent the griping of purgatives, and to disguise the taste of nauseous drugs. It depends for its properties chiefly on a volatile oil, *Oil of Pimento*, which is obtained from it by distillation with water, and is sometimes used to relieve toothache. The leaves are used for tanning, and a large trade is carried on in young shoots of the tree. From 3000 to 4000 bundles (500 to 800 in each bundle) are shipped annually from Jamaica for sticks for umbrellas. The crop of pimento in Jamaica, which alone furnishes the spice to commerce, varies. In 1888 it was 69,559 cwt., and in 1889, 46,179 cwt. The average receipts of the spice in England are about 4,000,000 lb.

Pimpernel (*Anagallis*), a genus of plants of the natural order Primulaceæ, having a wheel-shaped corolla, and the capsule opening by division round the middle. The species are elegant little annual and perennial plants, natives chiefly of temperate climates. The flowers are not large, but very beautiful. The Scarlet Pimpernel (*A. arvensis*) is a common plant in Britain, occurring as a weed in fields and gardens; it is common also in most parts of Europe and in many parts of Asia. The flowers are of a fine scarlet colour, with a purple circle at the eye. There is a common belief in England, mentioned by Lord Bacon, that when this plant opens its flowers in the morning a fine day may be expected; and they certainly close very readily on the approach of rain; hence the popular names it bears in some places—Poor Man's Weather-glass and Shepherd's Barometer. They usually open about eight in the morning, and close about noon. The Blue Pimpernel (*A. cærulea*) is far less common in Britain, but very abundant in some parts of Europe. The Bog Pimpernel (*A. tenella*), frequent in bogs in England, but rare in Scotland, is an exquisitely beautiful plant. Several species are cultivated in flower-gardens. Acrid properties prevail in this genus, and *A. arvensis* has been used medicinally in epilepsy, dropsy, and mania. The name Water Pimpernel is given to *Samolus valerandi*, also called *Brook-weed*, another British plant of the same order, with racemes of small white flowers, growing in watery gravelly places. It is supposed to be the Samolus which Pliny says the Druids gathered fasting, with the left hand, and without looking at it, ascribing to it magical virtues in the cure and prevention of diseases in cattle. Its geographic distribution extends over almost all the world.

Pina Cloth, a beautiful fabric made of the fibres of the leaves of the pine-apple plant. See FIBROUS SUBSTANCES, BROMELIACEÆ.

Pinchbeck is an alloy of zinc and copper, in which the proportions slightly differ from those of ordinary brass, which has 2 parts of copper to 1 of zinc; but 4 of the former to 1 of the latter constitute pinchbeck, which has a reddish-yellow colour, and was at the beginning of the 19th century much employed in making watch-cases and other small articles in imitation of gold. It was named after its inventor, Christopher Pinchbeck, a London clockmaker, who died in 1732. The term is now but little used.

Pinckney, CHARLES COTESWORTH, an American statesman, was born at Charleston, South Carolina, 25th February 1746, was sent to England and educated at Westminster and at Christ Church, Oxford, read law at the Middle Temple, and studied for a while at the military academy in Caen. He afterwards settled as a barrister at Charleston. He was Washington's aide-de-camp at the battles of Brandywine and Germantown, and afterwards, as colonel, saw much active service, until 1780, when he was taken prisoner at the surrender of Charleston, and detained till the close of the war. A member of the convention that framed the constitution of the United States (1787), he introduced the clause forbidding religious tests as a qualification for office. He declined the secretaryship of war in 1794, and of state in 1795; in 1796 he was sent as minister to France, but the Directory refused to receive him, and he had to quit the country. It was while on this mission that, when it was intimated that peace might be granted in return for a money payment, he made the reply, 'Millions for defence, but not a cent for tribute.' In 1804–8 he was twice an unsuccessful Federalist candidate for the presidency. He died 16th August 1825.

Pindar (Gr. *Pindaros*), the chief lyric poet of Greece, was born about 522 B.C. of Theban family at Cynoscephalæ, near Thebes, the capital of Bœotia, a district in which music and poetry were widely cultivated. His family, the Ægeidæ, was an old and illustrious one, often mentioned in the heroic legends. His father or his uncle was a flute-player, and Pindar inherited the musical talent of his family. He made music and poetry his profession, and was placed under the tuition of Lasus, a well-known musician and poet, at Athens. Though Thebes was the bitter foe of that city, Pindar often speaks of Athens with love and veneration. But Pindar seems, as a poet, to have been influenced far more deeply by Corinna and Myrtis, two poetesses then famous, with whom he competed for the prize at public contests. Corinna five times gained the victory over him. She assisted the young poet with her advice, judiciously as it would seem. It is said that she urged him to introduce mythical subjects into his poems, and then, when he had composed an ode introducing almost the whole Theban mythology in the first six verses, she smiled and said: 'We ought to sow with the hand, and not with the whole sack.' He commenced his career as a composer of choral odes for special occasions at the early age of twenty with a song of victory which still remains (*Pyth.* X., composed in 502). He soon reached the highest rank in his profession, and composed odes for persons in all parts of the Greek world. He was employed by the Sicilian rulers, Hiero of Syracuse and Thero of Agrigentum, by Arcesilaus of Cyrene and Amyntas of Macedon, as well as by the free cities of Greece. Wherever he went, he was honoured and loved for his own sake as well as for his art. States vied with one another in doing him honour; great cities like Athens created him their public guest. Though a frequenter of princely houses and king's palaces, he never lost his independence. In his poems he gives advice and reproof as well as praise to his patrons. He warns

the great Hiero to avoid flatterers, and cautions Arcesilaus of Cyrene against undue severity. He resided four years at the court of Hiero. He died about the age of eighty in 443 B.C. Two conquerors—Pausanias, king of Sparta during the Peloponnesian war, and later Alexander the Great, who left no other dwelling in Thebes standing—spared the house of Pindar.

Pindar was in the prime of life when Salamis and Thermopylæ were fought, when Greek energy and enterprise were at their highest, and Greek poetry and philosophy were opening into their richest blossom. But his poetry belongs to the old rather than the new period of literature. In spite of his admiration for Athens, which he calls 'the pillar of Greece,' the spirit of Athens did not lay hold of him. Intellectually, he stands nearer to the age of Homer than to that of his contemporary Æschylus. Pindar's language is Epic, tinged with Doric. He wrote an immense number of poems, including hymns to the gods, pæans, dithyrambs, odes for processions (*prosodia*), mimic dancing songs (*hyporchemata*), choral songs of maidens (*parthenia*), convivial songs (*skolia*), dirges (*threnoi*), and odes in praise of princes (*encomia*). Of all these poems we possess fragments only, often very beautiful, but his *Epinikia* or Triumphal Odes have come down to us entire. They are divided into four books, celebrating the victories won respectively in the Olympian, Pythian, Nemean, and Isthmian games. The special occasion for which these odes were composed explains their character. A victory won either in the chariot-race, for prowess in wrestling or other exercises, or for skill in music was held to confer honour not only on the winner and his family, but also on his city, and received a solemn celebration. It began with a procession to the temple, where sacrifice was offered, followed by a banquet, and concluding with a boisterous revel (*comus*). Thus the festival was partly religious, partly convivial and joyous. For the occasion an ode was composed, and was sung by a chorus either during the procession or, more frequently, at the comus. An intense enthusiasm for athletic sports was one of the most distinctive features of the Greek, as of the English national character. The performance of a triumphal ode by a trained chorus to the music of lyre and flute, amid an enthusiastic concourse of the victor's townsmen, must have been one of the most stirring events of Greek civic life. Pindar treats the victory not as a mere incident, but as connected with the victor's whole life and history. He loves to dwell on the *moral* side of it, not merely on the bodily prowess which gained it, but on the temperance, love to parents, or piety which secured the favour of the gods who granted success. And this is to him no mere poetic fiction, for he has the sincerest faith in the divine superintendence. But it is too much to say, as Paley does (Trans. Pref. p. viii.), that Pindar shows 'unquestioning credulity in the wildest legends.' Of myths relating things unworthy of the gods he says with emphasis: 'I cannot think this way of divine beings!' (as of the myth of Pelops, *Ol.* i., and another regarding Hercules, *Ol.* ix.). The plan of his poetry is intricate, and the connection of the different parts is often very hard to see. Pindar takes up various trains of thought, either relating to the victor, his ancestors, the history of his city, or else moral reflection; he breaks off each of these before the application is seen, and it is not till the end of the poem that he weaves the different threads together and explains the allusions. Thus, says Müller, 'the curiosity of the reader is kept on the stretch throughout the entire ode.' The great merit of Pindar's poetry is its vividness and picturesque power, seen even in single epithets, as when he calls the mountain-mass of Etna, overtowering all heights in the island, 'the forehead of fertile Sicily.' It is this vigour and vividness which suggest Mrs Browning's picture of 'bold, electric Pindar . . . with race-dust on his cheeks,' and eyes that seem to see 'the chariot rounding its last goal.' The description of the happy lot of the good after the final judgment in the Islands of the Blessed (*Ol.* ii.), the voyage of the Argonauts (*Pyth.* iv.), and the vivid picture of the eruption of Etna in the First Pythian illustrate this power. To us his poems are specially interesting because they show as in a mirror the intense admiration of the Greeks for bodily prowess, strength, endurance, and beauty. Such gifts rouse in him a feeling of religious veneration; they come from the gods and are sacred. The groundwork of Pindar's poems consists in those legends which form the Greek religious literature. It will be seen that his life was intimately associated with the observances of Greek religion. In connection with the worship at Delphi he received unique honours. The belief in his devoutness as a worshipper of the gods shows itself in the legend, which apparently sprang up during his life, that the god Pan was seen and heard in a glade between Cithæron and Helicon singing one of Pindar's hymns. When once asked what sacrifice he intended to offer at Delphi, he answered 'a pæan,' a reply not presumptuous, for his odes are full of religious feeling, not formal but real. His protest against myths dishonouring to the gods shows a truly reverent nature and an enlightened belief. Both in its strength and in its deficiencies his poetry reminds us of his claim on his own behalf: 'That man is wise *who knows much by natural genius;*' but the poets, his rivals, '*those who have learned*, the versatile talkers, are but as crows vainly chattering against the divine bird of Zeus.' Thus the distinction between genius and talent is as old as Pindar's time. This high faith in his own poetic inspiration must not be mistaken for self-confidence; but it almost verges on a contempt for art which seems responsible for the frequent intricacy and obscurity of his poetry.

See Böckh (1811–21); Dissen (1830; re-edited by Schneidewin, 1840–47—commentary excellent, but, owing to Schneidewin's death, incomplete); Fennell (1879–83); Bury, *Nemean Odes*, 1891; translations by Cary in verse (1833), Paley (occasionally powerful, but arbitrary; 1869), E. Myers (2d ed. 1883). K. O. Müller's chapter (Müller and Donaldson's *History of Greek Literature*) is full of excellent criticism.

Pindar, Peter. See Wolcot.

Pindaris, or Pindarrees, bands of freebooters or mercenary soldiers who, after the overthrow of the Mogul empire of India, grew (1804–17) to be a formidable power in the Central Provinces, their headquarters being at Malwa. Hastings, to put an end to their depredations, gathered two armies (120,000 men in all) in 1817 and crushed them.

Pind Dadan Khan, a town in the Punjab, stands one mile N. of the Jhelum and 110 miles NW. of Lahore. The people (16,724) make brass and copper utensils, pottery, whips, boats, and woollens, and carry on a large trade.

Pindus. See Greece, Vol. V. p. 384.

Pine (*Pinus*), a genus of trees of the natural order Coniferæ (q.v.). Pinus is distinguished by monœcious flowers, and woody cones with numerous two-seeded scales, the scales having an angular truncated apex. The leaves are linear and very narrow, growing in clusters or in pairs, and surrounded by scarious scales at the base. To this genus belong many noble and useful trees. They mostly grow in mountainous or other exposed situations, and their narrow leaves are admirably

adapted to evade the force of winds, which produce in the tops of pines a peculiar sound, much noticed by the ancient poets, more soft and continuous than in trees of richer foliage. Most of the pines are more or less social, one kind often covering a considerable tract; some of them clothing the sides and even the summits of mountains with magnificent but sombre forests; some growing in lower situations, on otherwise unproductive sandy grounds, as the *Pine Barrens* of North America. The pines growing in the most barren soils, or in the coldest climates and most exposed situations, are often very small, and, although very unlike any other shrubs or bushes, are scarcely to be called trees. Pines are widely diffused over the northern hemisphere, being found on mountains within and near the tropics, and in the colder temperate and the arctic regions descending to the level of the sea.

The Scotch Pine, commonly but erroneously known as the Scotch Fir (*P. sylvestris*), is the

Fig. 1.—Scotch Pine (*Pinus sylvestris*):
a, young shoot with female flower; *b*, twig with male flower; *c*, female flower; *d*, ripe cone; *e*, the same, opened; *f*, pair of needles with section.

only species indigenous to Britain. It has leaves in pairs, about an inch and a half long, the cones about the same length, obtuse, and with unarmed scales. On very poor soils and at great elevations it is reduced to a kind of shrub, but in favourable situations it becomes a lofty tree. A plank five feet and a half in diameter has been obtained from a Scottish forest. The Scotch pine is of quick growth, but has been known to attain the age of 400 years. Its head is somewhat conical or rounded, and the lower branches die off as the tree grows, leaving the older trees bare of branches for the greater part of their height; but it is more apt to send off large branches than most of the Coniferæ. There are still native forests of Scotch pine at Braemar and elsewhere in the Highlands of Scotland; and even in the south of Scotland noble trees are to be seen which, probably, were not planted by man. The Scotch pine is not indigenous to the south of England, but, having been introduced, is spreading rapidly and spontaneously, along with the Pinaster, in some of the heaths and other unfertile tracts. Immense forests of it exist in some countries of Europe, in some of which it is mingled with the Spruce Fir. In the middle and north of Europe and of Asia it is found even in plains near the level of the sea, especially where the soil is somewhat sandy; in the south of Europe it grows only on mountains. Its timber is highly valuable, being very resinous and durable, and is the *Red Deal* or *Red Pine* used in house and ship carpentry. There is very great difference, however, in the timber of Scotch pine growing in different soils and situations, rich soils and sheltered situations being unfavourable to the quality of the timber, which becomes white, soft, and comparatively worthless; and there exist several varieties of Scotch pine, some of which yield timber very superior to others. Many plantations in Britain have, unfortunately, been made of inferior kinds. One of the best varieties is that which forms the northern Scottish forests, often designated *Braemar Pine* by nurserymen. It is remarkable for its very horizontal branches, and is therefore sometimes called *P. horizontalis*. The Scotch pine is not only valuable for its timber, which is available for some purpose at every stage of its growth, but on account of other products. Common Turpentine is obtained from it, and much Tar, Pitch, Resin, and Lampblack (see these heads). Oil of turpentine is sometimes distilled from the cones, and even from the leaves; the leaves have also been used for the manufacture of Pine-wool (see FIBROUS SUBSTANCES, Vol. IV. p. 606). The resinous roots are dug out of the ground in many parts of the Highlands of Scotland, and, being divided into small splinters, are used to give light in cottages instead of candles. Fishermen, in some places, make ropes of the inner bark, which is applied to a very different use, when most soft and succulent in spring, by the Kamchatdales and Laplanders, being dried, ground, steeped in water to remove the resinous taste, and used for making a coarse kind of bread.

The Dwarf Pine (*P. Pumilio*) is found on the Alps and Pyrenees, its trunk often lying on the ground, although sometimes it appears as a bush or low tree. The leaves are in pairs, very like those of the Scotch pine, but a little longer; the cones

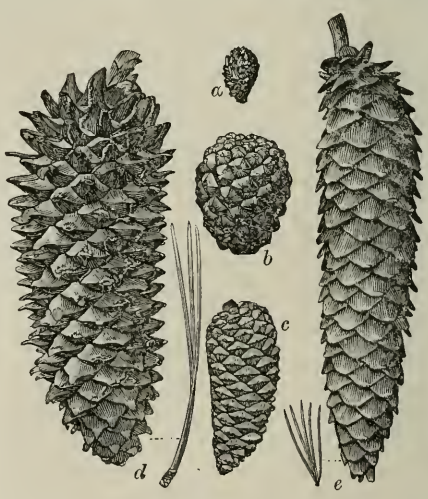

Fig. 2.
Cones of (*a*) *Pinus montana*; (*b*) *P. pinea*; and (*c*) *P. Pinaster*. Cones and needles of (*d*) *P. coulteri*; and (*e*) *P. Lambertiana*. All about ¼ natural size.

are also similar. From the young shoots an oil resembling oil of turpentine is obtained by distillation, which is a kind of universal medicine among the peasantry of Hungary, as is also the resin spontaneously exuding from the tree, which is known as *Hungarian Balsam*. The Black or Austrian Pine, or Black Fir (*P. nigricans*, or *P. austriaca*), is

another species closely allied to the Scotch pine, but remarkable for its very long leaves. It is a native of Austria. It abounds in resin more than any other European tree. To the same group of pines belongs the Seaside or Taurian Pine (*P. Pallasiana*, *maritima*, or *taurica*), which also affords resin in great quantity, and of a very pleasant odour. It is found in many parts of the south of Europe. Its timber is of little value; but great part of the turpentine of the Landes and other maritime districts of France is obtained from it. It yields also part of the *Burgundy Pitch* of the apothecaries' shops. The Aleppo Pine (*P. halepensis*), a native of the south of Europe, Syria, &c., is a very graceful tree of moderate size, with leaves in pairs and slender. It yields a liquid resin or turpentine, which is extracted from it in Provence and elsewhere, and sold as *Venice Turpentine*. The wood is extensively used in the Levant for shipbuilding. The Laricio (*P. Laricio*) has leaves in pairs, lax, and 4 to 8 inches long, cones 2 to 4 inches long, with the scales slightly pointed. It is often called the Corsican Pine. It grows on the shores of the Mediterranean Sea, and is valuable both for its timber and for its resinous products. In the island of Corsica it frequently attains the height of 140 feet. It grows well in sandy soils, and has been made particularly useful for preventing the drifting of the sand, and turning to account the otherwise useless tracts between the mouths of the Garonne and the Adour in France, thus also preserving valuable lands which the sand threatened to overwhelm. The Pinaster or Cluster Pine (*P. Pinaster*) is another of the most important European species. It has cones in whorls of 3, 4, or even 8 together, 4 to 6 inches long, leaves in pairs, and very long. It is found on the shores of the Mediterranean, and also in the Himalayas and in China. It has been used in France to a great extent, in the same way as the Laricio, for covering waste sandy tracts. The timber is of inferior quality, but great quantities of resin are procured from it. It yields *Bordeaux Turpentine*. The Pyrenean Pine (*P. pyrenaica*) is a majestic tree, a native of the Pyrenees, and producing very fine timber. The Calabrian Pine (*P. bruttia*) somewhat resembles the Pinaster. The Stone Pine (*P. pinea*), a tree with a broad umbrella-shaped head, a form often seen also in the Scotch fir, forms a characteristic feature of the scenery of the Mediterranean. It is the *Pinie* of the Germans, the *Pignon* of the French. The leaves are in pairs, 4 to 5 inches long, the cones very large, ovate, and obtuse. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and when fresh, have a sweet taste resembling that of almonds. They are used in Italy and other countries in the same way as almonds and pistachio nuts for the dessert, in various dishes, also in emulsions, &c., under the names of *pinies*, *pinnoles*, and *pignons*. The use of them, however, is almost entirely confined to the countries in which they are produced, as they very soon become rancid. They are sometimes imported into London in the cone, in which way they can be kept longer, but the cost of importation is much increased. The wood of this tree is very useful and beautiful. It yields resinous products only in small quantity. The Cembra Pine, or Swiss Stone Pine, which grows in the central parts of Europe and the south of Siberia—a stately tree, with the lower branches more persistent than they are in most pines, and rigid leaves in groups of three to five—also produces eatable seeds (*Cembra Nuts*). The Cembra Pine yields a pellucid, whitish oil, resembling oil of turpentine, and known as *Carpathian Balsam*.

North America produces many species of pine, some of them very beautiful and very valuable. Besides those long known, and which are found in the states and colonies near the Atlantic, a number of the noblest species of this genus have, since the commencement of the 19th century, been discovered in California and the north-western parts of America. The Red Canadian Pine (*P. resinosa*) is found from Canada to the Pacific, but does not reach far south in the United States. It is the Yellow Pine of Canada and Nova Scotia. It delights in dry and sandy soils, and attains a height of 70 to 80 feet, with a diameter of 2 feet at the base, the trunk continuing of uniform diameter for two-thirds of its length. The leaves are in pairs, and are congregated towards the extremities of the branches. The timber is highly esteemed for strength and durability, and furnishes excellent planks for shipbuilding. It is also used for masts. Somewhat resembling this in botanical characters is the Scrub Pine, or Gray Pine (*P. Banksiana*), generally only 3 to 10 feet high, which begins to appear in the northern parts of the United States upon high mountains, and is interesting as an arctic species, extending farther north than any other. The Yellow Pine (*P. variabilis*, or *P. mitis*) abounds in the Atlantic states from New Jersey to Virginia. It is a tree 50 to 60 feet high, 15 to 18 inches in diameter at the base, with leaves 4 to 5 inches long, usually in pairs, but sometimes in threes upon the younger shoots. The timber is very extensively used for shipbuilding, and is largely exported to Great Britain. At Liverpool it is known as New York Pine. The Jersey Pine, or Scrub Pine (*P. niops*), abounds in the lower parts of New Jersey, and thence to the south-west. The leaves are in pairs, 1 to 2 inches long, the cones armed with strong spines. The tree is rarely 30 or 40 feet high. Great quantities of tar are made from it in Kentucky. The Pitch Pine (*P. rigida*) is a native of the northern and middle parts of the United States, often growing in great miry swamps, and attaining a height of 70 to 80 feet, and a diameter of 2 feet at the base. The leaves are in threes, varying much in length, as the cones do in size. Immense quantities of it are used for fuel. Tar and lampblack are sometimes made from it. The Loblolly or Old Field Pine (*P. tæda*) grows in dry and sandy soils in the lower parts of the southern states, often occupying lands exhausted by cultivation. Vast tracts never cultivated in the southern states are *Pine Barrens*, in great part covered with this species of pine. It attains a height of 80 feet and upwards, and has a wide-spreading crown. The leaves are 6 inches long, in threes, sometimes in fours on young branches; the cones 4 inches high, with strong spines. The timber is not of much value. The Long-leaved Pine, or Southern Pine (*P. palustris*, or *P. australis*), is perhaps the most important of North American forest trees. It furnishes the greater part of the tar, resin, pitch, and turpentine used in the United States. The timber is also very valuable, and is much used for shipbuilding. In England and the West Indies it is known as Georgia Pitch Pine. The tree attains a height of 60 to 70 feet, and a diameter of about 16 to 18 inches; the leaves are in threes, and about a foot long, the cones 7 to 8 inches long, and 4 inches in diameter, with small spines. The seeds are sometimes eaten. The White Pine (*P. strobus*), called in Britain the Weymouth Pine, from its having been largely planted by Lord Weymouth, attains a height of 150 feet, and a diameter of 5 feet and upwards. It has lax sub-triangular leaves in groups of five, and pendulous cones 4 to 5 inches long, with thin smooth scales. It is frequently planted in Britain and on the continent of Europe for its beauty. In its native country it abounds chiefly from lat. 47°

to lat. 43°, and southward to the Alleghanies. The timber is not strong, but easily wrought and durable. Of the species belonging to the north-western parts of America one of the most magnificent is *P. Lambertiana*, which is found on the Rocky Mountains between lat. 40° and lat. 43°, chiefly on sandy soils. It attains a height of 150 to 200 feet, and a diameter of 7 feet and upwards, almost to 20 feet. The trunk is remarkably straight, and destitute of branches for two-thirds of its height; the leaves in fives, the cones upwards of a foot long. The timber is white, soft, and light; and the tree produces great quantities of a pure amber-coloured resin, which, when the wood is partly burned, is changed into a somewhat saccharine substance, used by the Indians as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes. *P. flexilis* is found on the Rocky Mountains, near the head-waters of the Arkansas, and occurs almost to the limit of perpetual snow. It has a dense crown formed of numerous and remarkably flexile branches. The leaves are in fives. The seeds are used as food by hunters and Indians. *P. ponderosa*, another native of the Rocky Mountains, is a magnificent tree, remarkable for the heaviness of its timber, which almost sinks in water. The leaves are in threes, and 9 to 14 inches long. *P. Sabiniana*, *P. Coulteri*, and *P. insignis* are also noble species from the west of North America.

The Himalayas abound in pines, some of which rival in magnificence those of North-west America. The Bhutan Pine (*P. excelsa*), much resembling the Weymouth Pine in its botanical characters, and attaining a height of 90 to 120 feet, abounds in Bhutan, although it is not found in the neighbouring countries of Sikkim and Nepal. The wood is highly valuable, being durable, close-grained, and so resinous as to be used for flambeaux and candles. The Cheer Pine (*P. longifolia*) of India is a tree of remarkable and most graceful appearance, with leaves in threes, very long, very slender, and generally pendulous. It is abundant on the crests of hills in the lower Himalayas, growing at a lower elevation than the other pines. It is cultivated in some parts of India as an ornamental tree. It is much valued for its resin. The wood is used in India as a substitute for European deal. The Khasia Pine (*P. khasiana*) is peculiar to the Khasia Mountains, and has very much the general appearance of the Scotch pine. *P. Gerardiana*, a species with leaves in threes, is a large tree, a native of Nepal. The seeds are eatable. The mountains of India and the north-western parts of America produce numerous other species; Mexico has a number of very fine ones peculiar to itself; the mountains of St Domingo have one; the Canary Islands have one; China and Japan also have some. Most of those which have been named, and a number of others, are now readily to be procured in nurseries in Britain, although some of them only at prices which prevent any attempt at extensive plantation. Some wealthy noblemen and gentlemen devote a portion of their grounds to a collection of different kinds of pine, called a *Pinetum*. A few foreign species have become pretty common in plantations. Most of the pines are quite hardy in Britain, but this is not the case with the Cheer Pine and some of the Mexican species. The name pine is often popularly extended, and even in scientific works, to other Coniferæ; many trees called pine being properly treated at Fir.

Pine-timber.—This term is in general use for the timber of the pine-tribe (see Coniferæ), and is not confined to that of the genus Pinus, but embraces the wood of species of Abies, Larix, Araucaria, Dammara, &c. From the Baltic ports come red wood and white wood. The former is yielded by the Scotch Fir (*Pinus sylvestris*), and the latter by the Spruce Fir (*Abies excelsa*). These two, with the Larch (*Larix europæa*), yield the greatest part of the pine-timber of Europe. Next in importance to these is the pine-timber of the British North American colonies, which is chiefly yielded by the Weymouth Pine (*Pinus strobus*). This wood is best known in America as white pine, but in Great Britain and in commerce generally it is called yellow pine. Commercially it is the most important timber of Canada and the eastern states of America. The yellow pine of this part of America is the *Pinus mitis*, also a valuable timber-tree. Red pine, usually called northern red pine (*Pinus resinosa*), is found from Canada to Pennsylvania; it is intermediate for durability between white pine and pitch pine. The celebrated pitch pine of the eastern states of America is the product of *Pinus rigida*. It is used for ships' masts and yards, and for purposes requiring great strength and durability, in both of which qualities it excels most others of its kind. The kinds above mentioned are those which constitute the greater part of the pine-timber used in ship and house building, carpentry, &c. in Great Britain and the eastern side of America. In France the timber of the Corsican Pine (*Pinus Laricio*) and the Seaside Pine (*Pinus Pinaster*) are greatly used. In Central and Southern Italy the pine-timber is chiefly yielded by the Stone Pine (*P. pinea*) and the Calabrian Pine (*P. bruttia*); that of Spain is from the Pyrenean Pine (*P. pyrenaica*). In Germany, and especially in Austria, the Black Pine (*P. austriaca*) furnishes the greater portion; but the fine-grained, soft white pine, or deal, so much used for sounding-boards of musical instruments, is the wood of the Silver Fir (see Fir). The trade in this timber is very great, for not only do the Germans use it almost exclusively in their vast toy manufactories and for lucifer matches, but considerable quantities are exported. The finest is cut in the forests of Bohemia, where large establishments are formed for dressing and preparing the wood for various purposes.

Several other kinds of pine-timber are imported into Europe, but those mentioned form the great staples of the timber-trade. The chief value of this class of timber-woods is in the combination of lightness and strength with softness of texture and ease in working with ordinary tools; they constitute, in fact, the principal materials of European and American builders, and are more used than all other kinds of wood together. Much confusion prevails as to their common designations, for in Britain alone *fir*, *pine*, and *deal* are terms applied to all and each of them, according to the caprice of the individual. The first two names are used because the material is derived from one or other of those genera; but the last is a misnomer altogether, as the term deal belongs only to pieces of fir or pine timber cut to particular sizes: they are 3 inches in thickness, 9 inches broad, and of variable length; if of less width, they are called *battens*. See Timber.

Pineal Gland, a rounded body about the size of a pea, of a slightly yellowish colour, situated upon the anterior pair of corpora quadrigemina, and connected with the optic thalami by two strands of nerve-fibres termed its peduncles (see Brain). It contains small cavities in its interior. The function of the gland has long been matter of speculation. It was regarded by Descartes as the seat of the soul. It has been recently discovered to be a developmental remnant of a third eye, the elements of which can still be distinctly traced in some of the lower vertebrata. See Sphenodon.

Pine-apple, or ANANAS (*Ananassa sativa*), a plant of the natural order Bromeliaceæ, highly esteemed, and much cultivated for its fruit. The fruit is a *sorosis*, formed by the calyces and bracts of a close spike of flowers, becoming succulent and combined. This is the distinctive character of the genus Ananassa. The pine-apple has a number of long, serrated or smooth-edged, sharp-pointed, rigid leaves, springing from the root, in the midst of which a short flower-stem is thrown up, bearing a single spike of flowers, and therefore a single fruit. From the summit of the fruit springs a crown or tuft of small leaves, capable of becoming a new plant; the pine-apple, in cultivation, being propagated entirely by crowns and suckers, as, in a state of high cultivation, perfect seed is almost never produced. The pine-apple is a native of tropical America; it is found wild in sandy maritime districts in the north-east of South America, but it has been very much changed by cultivation. It has also been gradually diffused over tropical and subtropical countries, and not only as a cultivated plant, for it is fully naturalised in many parts both of Asia and Africa. It delights

Pine-apple (*Ananassa sativa*).

in a moist climate, and consequently does not succeed well in the dry climate of the south of Italy, although the warmth is sufficient. The first particular account of the pine-apple was given by Oviedo in 1535. It was in Holland that it first began to be cultivated in hothouses; but it was introduced into England from that country in 1690, and first cultivated by Mr Bentinck, ancestor to the ducal family of Portland; and its cultivation rapidly became general in the gardens of the wealthy. It is only since the peace of 1815 that it has received similar attention in continental Europe. Great care is requisite in the cultivation of the pine-apple, which without it is generally fibrous and coarse, with little sweetness or flavour, and with it one of the most delicate and richly flavoured of fruits. Its size, too, very much depends on cultivation, but there is also considerable difference in the size of the fruit in different varieties, the largest not being always the most luscious and superior in flavour. The size varies from 2½ lb. to 12 lb. in weight. The pine-apples grown in British hothouses are generally much superior to those of the West Indies, because the latter grow almost or altogether without cultivation: but the importation of pine-apples from the West Indies has now been carried on to a considerable extent, and, as it promises to add to the sources of wealth for these colonies, this has led to greater care in cultivation there, and consequent improvement of quality.

Formerly the culture of the pine-apple in Britain was a costly and extremely tedious process. Since very early after its introduction it has always been cultivated in hothouses specially appropriated to it called pine-stoves, which were heated with smoke-flues, with tanners' bark or oak-leaves and dung for bottom heat. But by the universal adoption of hot water in horticultural heating the labour and cost attendant on those clumsy expedients have been much reduced and better results attained. Along with this there has been brought about a more rational treatment of the plants. Instead of high tropical ground and atmospheric heat being maintained in winter, which resulted in destroying the roots of the plants in the preliminary stages of their growth, and so retarded or deferred their fruiting period, the skilful pine-grower now finds that success is best assured by adopting a minimum of 60° of air-warmth and 75° of bottom-heat at that season. By these and other improvements in treatment superior fruit is obtained in half the time formerly considered necessary. The pine-apple is cultivated in pots or planted out in beds. It is more completely under control in pots than planted out, hence the results are always more certain when it is grown in that way. It is propagated by suckers and by the crowns that surmount the fruit; but, except in the case of varieties which produce the former too sparingly for the requirements of stock, the latter are usually rejected because they do not make so good plants nor fruit so quickly as a rule. The varieties of the pine-apple that are worthy of being cultivated in Britain are few. For producing superior fruit in winter the Smooth Cayenne and Black Jamaica are two of the best and most reliable, and the Queen, of which there are several sub-varieties, is the most highly esteemed for summer fruiting. Turfy, fibrous, sandy loam that has lain in a stack for nine or twelve months is an excellent soil for the pine-apple. A spirituous liquor (*Pine-apple Rum*) is made from the pine-apple in some warm countries. The use of the fibre of the pine-apple is noticed in the articles BROMELIACEÆ, FIBROUS SUBSTANCES. For Pine-apple Oil, see BUTYRIC ETHER.

Pine-beetle. See BARK-BEETLE.

Pine Bluff, capital of Jefferson county, Arkansas, is built on a high bluff on the south bank of the Arkansas River, about 120 miles from its mouth, and 43 miles by rail SSE. of Little Rock. It contains large ironworks, ships a good deal of cotton, and manufactures cotton-seed oil, flour, lumber, bricks, &c. Pop. (1890) 9952.

Pinel, PHILIPPE, a Parisian physician (1745–1826) who gained for himself undying fame by his reformation of the old barbarous methods of treating the insane. See INSANITY.

Pinero, ARTHUR WING, born in London in 1855, studied law, but in 1874 made his début on the stage at Edinburgh, and in 1875 joined the Lyceum company. He is the author of a number of successful plays, including *The Squire* (1881), *The Rocket* (1883), *Sweet Lavender* (1888), *The Second Mrs Tanqueray* (1893), *The Notorious Mrs Ebbsmith* (1895), and *The Gay Lord Quex* (1899).

Pinerolo, or PIGNEROL, a town of North Italy, at the east foot of the Alps, 23 miles by rail SW. of Turin. Originally a town of Savoy, it was regarded as the key of Italy. In its strong citadel, the Man with the Iron Mask, Lauzun, and Fouquet were imprisoned. This fortress was in French hands from 1536 to 1574, again from 1630 to 1696, from 1704 to 1706, and from 1801 to 1814. The town contains a cathedral and a technical school. Cloth, paper, leather, cotton, and silk are manufactured. Pop. 12,003.

Pine-tree Money, silver money coined at Boston, Massachusetts, in the 17th century (from 1652), and so called from the coins' bearing the rude figure of a pine-tree on one side.

Pine-wool. See FIBROUS SUBSTANCES.

Pink (*Dianthus*), a genus of plants of the natural order Caryophyllaceæ, of which there are many (some 230) species, annuals and perennials, with beautiful and often fragrant flowers, chiefly natives of Europe and the temperate parts of Asia. The calyx is tubular, 5-toothed, with two or four scales at the base; there are five petals suddenly contracted at the throat of the corolla into a linear claw. There are ten stamens, and one ovary with two styles. The capsule is cylindrical and one-celled. The exquisite beauty of the flowers has attracted admiration in all ages; and some of the species have long been much cultivated in gardens, particularly the Garden Pink and Carnation (q.v.), which are often referred to one original, the Clove Pink (*D. caryophyllus*), a native of the south of Europe, growing wild on rocks and old walls, and naturalised in some places in the south of England; whilst some botanists refer the garden pinks with more probability in part to the Maiden Pink (*D. deltoides*), a pretty common British species, and those called Pheasant-eye pinks to the Feather Pink (*D. plumarius*), a native of some parts of continental Europe. The varieties of the garden pink and the pheasant-eye pink, which are usually designated the florists' pink, are of much less antiquity than the carnation as garden ornaments. Gerard scarcely mentions them, while in Parkinson's time they appear only to have been cultivated as other hardy perennials and annuals were, without any special care. Their capabilities as choice florists' flowers were recognised about 1810, and the number of varieties has since then greatly increased. Nearly allied to them is *D. superbus*, found in moist places in some parts of Europe, and not unfrequently to be seen in flower-borders. It has very fragrant flowers. Both single and double pinks are generally propagated by *pipings*, which are short cuttings of the younger shoots. They are also sometimes propagated by layers. A rich loamy soil is the best for pinks. The Maiden Pink is a small, much-branched plant, growing in grassy places, on gravelly and sandy soils; it has rose-coloured flowers spotted with white, and a white eye encircled by a deep purple ring. The Deptford Pink (*D. armeria*) and the Clustered Pink, or Childing Pink (*D. prolifer*), also natives of England, differ from these in being annuals, and in having clustered flowers. The Bearded Pink, or Sweet William (*D. barbatus*), a native of the middle of Europe and the south of France, with lanceolate leaves, flowers crowded in dense clusters at the top of the stem, acuminated bracts, and bearded petals, has long been a favourite garden-flower, still retaining its place alike in palace and cottage gardens. Although perennial, it is sown annually by florists, to secure fine flowers, and there are many varieties, single and double, exhibiting much diversity of colour. The Mule Pink, or Fielding's Pink, a choice kind, is supposed to be a hybrid between the Sweet William and the Picotee. The Indian Pink, or China Pink (*D. chinensis*), is now also common in flower-gardens. The Clove Pink was formerly regarded as possessing medicinal properties, and was used in nervous maladies. See F. N. Williams, *The Pink of Central Europe* (1890).—*Sea-pink* is a common name of Thrift (q.v.).

Pinkerton, JOHN, an acrid little book-maker, was born at Edinburgh, 17th February 1758, and after six years' schooling at Lanark, and five years' irksome apprenticeship to a W.S., in 1780 settled in London as a man of letters, in 1802 in Paris, where he died in indigent circumstances, 10th May 1826. His twenty-four works and compilations include some pseudo-archaic 'rimes,' ballads, &c.; *Essay on Medals* (1784); *Letters on Literature* (1785), marked chiefly by a novel system of inflection and orthography, but were the means of introducing him to Walpole and Gibbon; *Ancient Scottish Poems from the MS. Collections of Sir Richard Maitland of Lethington* (1786); *Dissertation on the Origin and Progress of the Scythians or Goths* (1787), in which he first fell foul of the whole Celtic race; *Inquiry into the History of Scotland preceding the Reign of Malcolm III.* (1790); *Iconographia Scotica* (1795–97); *History of Scotland from the Accession of the Stuarts to that of Mary* (1797); *Walpoliana* (1799); *Modern Geography* (1802–1807); *Voyages and Travels* (16 vols. 1808–13); *New Modern Atlas* (1809–15); and *Petralogy, or a Treatise on Rocks* (1811). See his *Literary Correspondence* (2 vols. 1830).

Pink-eye is a name commonly given to an epizootic disease which prevails among horses, and is called by veterinarians *Epizootic Cellulites;* also Rheumatic Influenza, or sometimes *Muco Enteritis.* The disease, which of late years has assumed a more virulent form, prevails during a continuance of wet weather, especially when it is also cold, and attacks a number of animals in various parts of a town or district almost simultaneously, thus proving its atmospheric origin; but, although it thus breaks out spontaneously, there is no doubt of its being an infectious disease. The primary symptoms are loss of appetite, dullness, perhaps rigors, with fever, manifested by elevation of the temperature, varying from about 104° to 107°, or, in very severe cases, even 108° F., and acceleration of the pulse. In slight cases the pulse may be 65, in very severe ones over 100 beats per minute. These symptoms are succeeded—but not always—by swelling of the eyelids and redness of the eye—hence the term pink-eye—pain in and stiffness of the limbs, with tumefaction, particularly around the joints. The swellings are at first limited, but soon extend upwards and downwards from the joints affected, and their occurrence gives relief to the pain. The digestive organs are disordered; there is generally constipation at first, the fæces are covered with much mucus, and in many instances there is some degree of colicky or intestinal pain. Some horses have a loud, hoarse cough, at first dry, but often becoming moist; but lung complications are not very common. In some instances the pulse gradually becomes very feeble, though the animal presents no other bad symptom, the pain having left the limbs, the appetite returning, the swellings diminishing, and the secretions regaining the normal condition; whilst an ordinary observer is confident of a rapid recovery, the animal suddenly dies, and a post-mortem examination reveals the presence of ante-mortem clots of blood in the cavities of the heart, and perhaps in the great pulmonary blood-vessels. To the veterinarian the apparently convalescent stage is a most critical condition, and he must endeavour, by rousing the heart's action, to prevent the formation of these coagula.

As a rule the disease runs its course favourably in from four to ten days, leaving the animal with more or less loss of condition and strength, but both are soon restored by good nursing and gentle exercise. The treatment which has proved most successful is based on the conclusion that the disease runs a definite course, and that all attempts to check this are calculated to do more harm than good. It is most important that all who have the care of horses should know that it is most dangerous to work a horse when this disease prevails after

he has manifested the slightest loss of appetite; many horses turned out to work after failure of appetite have been brought back a few hours after in a dying condition. The medicines made use of are those which moderate pain if excessive, keep the contents of the stomach and bowels from undergoing putrefactive fermentation, and act as very slight aperients; and, when the heart's action threatens the condition above described, cardiac stimulants, such as the bicarbonate of ammonia given in a ball. Alcoholic stimulants, in virtue of their irritating properties and their effect on the nervous system, are very injurious, and should not be administered in this nor in any other disease where the so-called fibrinous state of the blood is one of the conditions.

Pinkie, a battle fought on 10th September 1547 near Musselburgh in Midlothian between 14,000 English under the Protector Somerset and twice that number of Scots. The latter were utterly defeated, more than 10,000, it is said, being killed on the field and in the pursuit, whilst the English loss was barely 200.

Pink Root. See SPIGELLA.

Pinna, a genus of bivalves, not far removed from mussels (Mytilidæ). The shell is acutely triangular, beautifully translucent, and in some species measures two feet in length. The attaching byssus, especially of the Mediterranean species (*P. nobilis*), is very long and silky, and admits of being woven into fabrics. So the ancients occasionally used it, and, to gratify the curious, byssus-gloves, &c. are still made at Taranto and elsewhere. The animal is sometimes eaten. It lives from low-water to sixty fathoms.

Pinnace. See BOAT.

Pinnipedia. See SEAL.

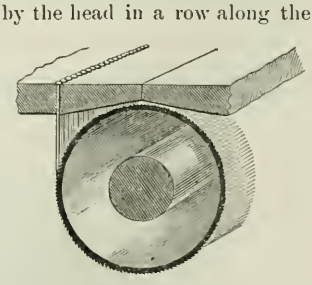
Pinnock, WILLIAM (1782–1843), who is famous in the educational world as the originator of the formerly well-known catechisms which bear his name. To Samuel Maunder (q.v.), his brother-in-law, he was chiefly indebted for the production of these catechisms, which finally extended to 12 volumes, or 83 separate parts. Histories of England, Greece, and Rome ran through more than a hundred editions.—His son, WILLIAM HENRY PINNOCK, LL.D. (1813–85), vicar of Pinner, studied at Cambridge, and wrote on church law and church history.

Pinos, ISLA DE, a Spanish island in the West Indies, south of Cuba, of which it is the largest dependency. It was discovered by Columbus in 1494, has an area of 1200 sq. m., part low and swampy, and part hilly (1500 feet), and is clothed with fine meadows and woods, and produces silver, quicksilver, and iron. It was once notorious as the resort of pirates. Pop. 2200.

Pins. The earliest kinds of pins, or of spikes serving the same purpose as pins, were probably thorns or the small bones of fish and other animals. Among the remains found on the sites of the prehistoric lake-dwellings of Europe there are numbers of bone pins, some of a rude and others of an elegant form. The great majority of the pins in these 'finds' are, however, of bronze; but a few of copper and one of iron have also been discovered. It is estimated that 10,000 pins have been collected at the lacustrine stations of Switzerland alone. They seem to have been chiefly used as hair-pins, though no doubt they were also employed to fasten the dress, and for other purposes. The forms of these ancient pins are extremely varied, and in the numerous cases where they have ornamented heads the patterns are often curious and beautiful. A few have double stems like modern hair-pins, and three found at Peschiera are exactly the same in form as the 'safety pins' which have come largely into use in recent years. Many of the single stemmed ones are baluster shaped—i.e. they are thicker at some places than at others. A good many both of bone and of bronze have a head formed of a loose ring in an eye. Some have bulbous heads (these occasionally being of amber) very like the scarf-pins of the present time. For numerous illustrations of these ancient pins, see Munro's *Lake-dwellings of Europe* (1890).

Among ancient articles for the toilet found in Egypt some pins with gold heads occur, and ancient Roman bronze pins and bone hair-pins, with ornamental heads, have been found at Pompeii. As regards modern pins, it was about 1840 that the solid-headed kind now in common use took the place of the older form of pin, which had a globular head of fine twisted wire made separately and secured to the shank by compression from a falling block and die. These old pins had the disadvantage of frequently losing their heads. They were made by manual labour in such a way that each pin passed through the hands of fourteen different persons (see DIVISION OF LABOUR).

Solid-headed pins are made by an improved form of a machine which was patented in England by an American, named L. W. Wright, in 1824. But before this machine was perfected enough to do its work properly many thousands of pounds were expended upon it. Pins are made by the modern machine in this way: Pincers draw from a reel of wire a length sufficient to make a pin, which is at the same time straightened by passing between fixed studs. The pin length is seized by lateral jaws, from which a portion of the wire is left projecting. A snap head die next advances to partially shape the head; the jaws or grippers then release it, and the pin is pushed forward again about a twentieth of an inch, when the head gets another squeeze of the die. These movements of the machine are repeated once more to finish the head, and the wire is then cut to the length of a pin. The headed blanks drop into a receptacle and arrange themselves in the line of a slot formed by two inclined and bevel-edged bars. The opening between the bars is just wide enough to let the shank of the pin fall through, so that by the action of the machine the blanks become suspended by the head in a row along the slot. When the blanks reach the lower end of the inclined bars they are caught, still hanging downwards, between two parts of the machine (one of which has a suitable movement), and passed along, rotating as they move, in front of a cylindrical cutter, with sharp grooves on its surface, so that it acts like a file, and points the pins. The annexed figure from the *Engineer* of June 3, 1887, shows this part of the machine, which makes pins at the rate of 160 per minute.



Ordinary pins are made of brass wire, and when these are finished by the machine they are cleaned of grease and other matters by boiling them in weak beer. The pins are next coated with tin, or 'coloured,' as it is called. In this process alternate layers of pins and grain-tin are placed in a copper pan, to which water is added, along with some argol or crude tartar (bitartrate of potash). When heat is applied a solution of tin is produced from which the metal is deposited on the surface of the

pins, giving them their silvery white colour. The tin surface is afterwards brightened by shaking them in a bag or barrel with bran or sawdust. Pins are 'papered' by a self-acting machine not less ingenious than the one by which they are made.

For mourning pins iron wire is used, and these are either 'blued' by heating them in a muffle till the proper tint is obtained, or made black by coating them with a suitable varnish, which is afterwards hardened by stoving the pins. The finest and most costly pins are those made of hair-like wire for insect collectors. 'Blanket' pins are about 3½ inches long, and various sizes between 1½ inch and ⅝ths of an inch in length are made for domestic use. Safety pins with the point resting in a loop, now so much used in the nursery and for other purposes, were, as already stated, made in prehistoric times; at least pins of exactly the same form were. The manufacture of pins is largely carried on at Birmingham, and to a less extent at London, Warrington, Stroud, and Dublin. They are also extensively manufactured in the United States—chiefly in Connecticut.

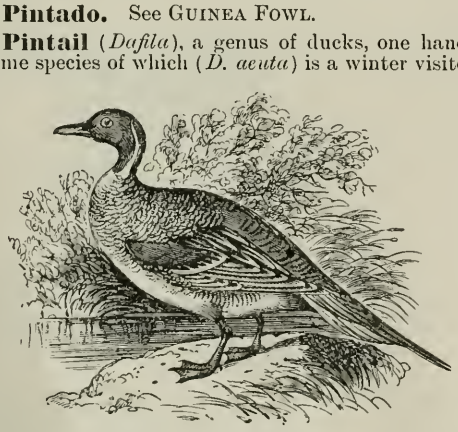
Pinsk, a town of west Russia, stands in the midst of what were formerly vast marshes (in large part drained since 1875), on a branch of the Pripet, 98 miles by rail E. of Brest-Litovsk, manufactures leather, and has a large transit trade. Pop. 32,408, two-thirds being Jews.

Pinsuti, Ciro, musical composer, was born at Sinalunga, near Siena, on 9th May 1829. He studied music at Bologna (1845), and was a special pupil of Rossini. From 1848 to 1885 he lived in England as teacher of singing, chiefly at London and Newcastle. From 1856 he taught singing at the Royal Academy of Music. As a composer he wrote charming music for songs (more than 300 in all). In celebration of the union of Tuscany with Italy in 1859 he composed a Te Deum, but was not successful as a writer of larger musical compositions. He died at Florence, 10th March 1888.

Pint, a measure of capacity used both for liquids and dry goods, and equivalent to the eighth part of a Gallon (q.v.), or 34·65925 cubic inches. The Scotch pint, superseded as a legal measure by the imperial pint, was equivalent to 3·0065 imperial pints.

Pintado. See Guinea Fowl.

Pintail (*Dafila*), a genus of ducks, one handsome species of which (*D. acuta*) is a winter visitor



Pintail Duck (*Dafila acuta*).

to many parts of the British coast. It is a native of all northern regions, is elongated in form, and very rapid in flight. Its flesh is much esteemed.

Pinto, Fernam Mendez, Portuguese adventurer, born at Montemor-o-Velho, near Coimbra, about 1510. When twenty-seven years of age he made his way out to India, and remained twenty-one years in the south and south-east of Asia, leading the life of an adventurous seaman, fighting pirates at one time, trading at another, and again being employed on special missions to Japan or elsewhere, his fortune often fluctuating between great wealth and poverty. He returned home to Portugal in 1558, spent much time in writing an account of his adventures, adding to them many exaggerations and gross fictions, and died at Almada near Lisbon, probably in 1583. His travels—*Peregrinaçam*—were not published until 1614, but have since then been translated into several European languages—into English by F. Cogan in 1663. See a new abridged edition of those travels, with an introduction by A. Vambéry (1891).

Pinturicchio, whose proper name was Bernardino di Betti, was a painter, born at Perugia, in 1454. An assistant to Perugino, he helped him with the frescoes in the Sistine Chapel at Rome, and then spent the best part of eight years (1484–92) in painting frescoes on the walls of the chapels of Santa Maria del Popolo in Rome. After executing two pieces in the cathedral at Orvieto he decorated the walls of what is now the Vatican library with a series of six frescoes; this occupied him six years (till 1498). On the walls of Sta Maria in Ara Cœli he illustrated the life of St Bernardino of Siena. Other frescoes by his brush adorned two churches in Spello, the Petrucci Palace at Siena, and the cathedral library in the same city, this last series illustrating the life of Pope Pius II. All these works are admirable examples of decorative art. Pinturicchio painted a few panel pictures of high merit, as Christ bearing the Cross, two Madonnas enthroned (at Perugia), Coronation of the Virgin (in the Vatican), and others at Siena, Florence, and Spello. He died at Siena, 11th December 1513.

See Life by Vermiglioli (Perugia, 1837), two monographs by Schmarsow (Stutt. 1880 and 1882), and Milanesi's ed. (Florence, 1878) of Vasari, vol. iii.

Pinwell, George John (1842–75), born in London, drew on wood, did book illustration, and after 1865 became a water-colour painter of great eminence.

Pinzon, the discoverer of Brazil (q.v.).

Piombi, the notorious roof-cells (*sotto piombi*, 'under the leads') of the state-prisons of Venice (q.v.), in which Casanova and many other notable prisoners were confined. The heat in summer and the cold in winter are said to have been intense. Of late it has been asserted that they must have been comparatively pleasant abodes.

Piombino, a former principality of Italy, lies along the coast opposite the island of Elba, the greater part of which belonged to it. Its extent was 139 sq. m.; and its population, previous to its incorporation with Italy in 1860, about 25,000. Piombino, originally a fief of the empire, came in the 14th century into the possession of the Appiani, who, after ruling it for nearly 200 years, made way for the Buoncompagni, who were expelled by Napoleon in 1801; but after the Congress of Vienna the principality was put under the suzerainty of Tuscany. The town of Piombino (pop. 4000), on a promontory 50 miles S. of Leghorn, has iron-rolling mills.

Piombo. See Sebastian del Piombo.

Pioneer, in the British infantry, is a military artisan employed during peace in such work as painting and repairing barrack-rooms, &c., and in war marching at the head of each battalion to clear a passage for it through woods or other obstructions, improve roads, make bridges, and generally to do any minor engineering or constructive work

that may be necessary. One is selected from each company. Instead of a rifle each carries a saw-backed sword, an axe, and two gun-spikes, other necessary tools being distributed among them.

Cavalry Pioneers, one from each troop, are instructed at the School of Military Engineering, Chatham, in the best method of rapidly destroying railways, telegraph lines, &c., and carry gun-cotton and the tools necessary for this purpose.

Piotrkow (Ger. *Petrikau*), a town of Russian Poland, 87 miles by rail SW. of Warsaw. Cotton and wool spinning is largely prosecuted. It is one of the oldest Polish towns; here in the 15th and 16th centuries diets were held and the kings elected. Pop. 24,866.—The *government* has an area of 4730 sq. m. and a population of (1891) 1,200,197, and is a centre of the cotton and woollen industries, of brandy-distilling, and of corn-milling.

Piozzi, Mrs, more famous as Mrs Thrale, and by that name to be remembered until Dr Samuel Johnson is forgotten. Her maiden name was Hester Lynch Salusbury, and she was born of a good Welsh family at Bodvel in Carnarvonshire, January 27, 1741. She early gave promise of quick parts and lively disposition, and received an education that extended even to Latin as well as French, Spanish, and Italian. Early introduced into the fashionable world of London, in October 1763 she married Henry Thrale, a prosperous Southwark brewer, thirteen years her senior. He was an honest man, and made an indulgent, if somewhat indifferent, husband; but he was uncommunicative and phlegmatic in temperament. Mrs Thrale made Johnson's acquaintance through the kind offices of Murphy in January 1765, and one of the most interesting friendships in the history of letters at once began. The sage quickly conceived an extraordinary affection for his 'mistress,' was domesticated in her house at Streatham Place for over sixteen years, and for her sake learned to soften many of the eccentricities of his speech, dress, and behaviour. Of all his friendships this was the one most valuable to him, for Mrs Thrale's warm woman's heart and constant cheerfulness henceforward brightened many a gloomy hour in a life that had known but little happiness. Thrale also had a solid esteem for Johnson, carried him with the family to Brighton, to Wales in 1774, and to France in 1775, and left him £200 as one of his four executors. He was returned for Southwark at a by-election in the end of 1765, and sat continuously until the election of 1780. Boswell first visited Streatham in October 1769, Fanny Burney in August 1778. In 1772 Thrale's affairs became embarrassed, but his wife's tact and energy and the timely advances of friends enabled him to tide over the crisis. Thrale died in April 1781, and three years later the brewery was sold for £135,000. Mrs Thrale had borne him twelve children, but her only son died in 1776, and she had but five daughters living at her husband's death. Dr Johnson's health was now declining, and he soon began to feel himself slighted as the widow's affection for the Italian musician Piozzi began to occupy her heart. Their acquaintance had begun only in 1780, though they had met three years before. The proposed match met with the strongest opposition from Mrs Thrale's daughters and from Johnson, whose disapproval, in spite of slandering tongues, was in nowise due to personal disappointment. She left Streatham for Bath in October 1782, and a few letters on the subject of the marriage passed betwixt Johnson and herself in which it must be confessed that the woman shows to more advantage than the sage. But where Johnson loved he loved deeply, and that with a love that could bear no rival near the throne. 'A friendship of twenty years,' he writes, 'is interwoven with the texture of life. A friend may be often found and lost, but an old friend never can be found, and nature has provided that he cannot easily be lost.' The marriage, for some time postponed, actually took place at Bath, 25th July 1784, and the pair next travelled through France, Italy, Germany, and Belgium, returning to England early in 1787. Piozzi proved an inoffensive husband, managed their finances with prudence, and her daughters were at length reconciled—the eldest, Dr Johnson's 'Queenie,' married Lord Keith in 1808. Mrs Piozzi returned to Streatham in 1790, but soon after built Brynbella on the banks of the Clwyd. Here Piozzi died in 1809, and here his widow remained till 1814, living thereafter at Bath, Clifton, and Penzance. When past seventy she formed a sentimental attachment for William Augustus Conway, a handsome young actor, who drowned himself crossing the Atlantic in 1828. Fourteen years after his death seven letters from Mrs Piozzi to him were published. Their genuineness is doubtful, but, as Hayward points out, even taken as they stand, they do not amount to very much, while the change of two or three sentences would alter their entire tenor. In May 1821 Mrs Piozzi broke her leg while travelling from Penzance to Clifton, and died after ten days of suffering. She was buried beside Piozzi in the little church of Dymerchion in Flintshire.

Mrs Thrale was vivacious, frank, witty, thoroughly feminine, and charming, if somewhat wanting in refinement. She was pretty, if hardly beautiful—her face gave Hogarth his model in 'The Lady's Last Stake,' but the best portrait is that by Sir Joshua Reynolds. Baretti, Boswell, Peter Pindar, and Horace Walpole all abused her; but she lives secure of immortality in the love of Samuel Johnson, and in the happiness she brought into nearly twenty years of a life 'radically wretched.'

Mrs Piozzi had a fatal facility in composition, but two of her books at least live through their subject, and indeed are only less interesting than Boswell himself: *Anecdotes of Dr Samuel Johnson during the last Twenty Years of his Life* (1786; reprinted in Mrs Napier's *Johnsoniana*, 1884), and *Letters to and from Dr Samuel Johnson* (2 vols. 1788). Her *Observations and Reflections made in a Journey through France, Italy, and Germany* (2 vols. 1789), *British Synonymy* (2 vols. 1794), and *Retrospection, or a Review of the most striking and important Events*, &c. (2 vols. 1801) are long forgotten. Of her poems the 'Three Warnings' survives—it was first printed in the *Miscellanies* of Miss Williams (1766), a volume containing a prose-tale of Johnson's, 'The Fountains,' the heroine of which, Floretta, was a study of Mrs Thrale. Her notes to Wraxall's *Historical Memoirs* were reprinted in the 1884 edition of that work, as well as in Hayward; her *Autobiography, Letters, and Literary Remains*, by Abraham Hayward, in 1861 (2 vols.). See the Rev. Ed. Mangin's *Piozziana* (1833), Boswell's *Life of Johnson*, Madame D'Arblay's *Diary*, Mr Hayward's Introduction, and L. B. Seeley's *Mrs Thrale* (1891).

Pip is the name by which various diseases in both fowls and pheasants were once known, but since the affections of birds have been studied, and more accurate knowledge arrived at, this term is no longer in use. See Roup.

Pipa, a genus of Amphibians (q.v.), of which the best known is the Surinam Toad.

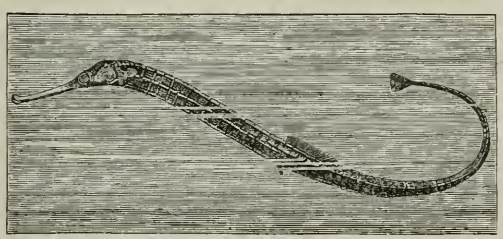
Pipal. See Peepul.

Pipe, a measure of quantity commonly employed in Portugal, Spain, France, England, and in some other countries, used almost exclusively for wine and oil. In England it is also called a butt, and is equal to two hogsheads. But the capacity varies with the locality as well as with the description of wine the cask contains: a pipe of port is 137

imperial gallons; of sherry, 130 imperial gallons; that of Madeira, 110 imperial gallons; while the common English pipe contains 126 wine gallons, or nearly 105 imperial gallons.

Pipeclay, a fine white plastic clay, very like kaolin, but containing a larger percentage of silica. For the manufacture of tobacco-pipes the most desirable clay contains only small traces of limonite and alkaline earths. Clays of this nature are met with in Cornwall, Devon, and Dorset, but the purer varieties of clay used for pottery-making are also employed in the manufacture. Such clays, however, have siliceous materials added to them artificially. Pipeclay is used by soldiers for whitening belts, &c.

Pipe-fish, a family of remarkable fishes in the same (Lophobranch) order as the Sea-horses. The body is elongated like a thin pipe; the jaws are prolonged in a tubular toothless snout; the muscular development is slight; the skin is covered with an armature of hard plates; the gills are in the form of tufts, and the branchial aperture is very small. The eggs are carried about and hatched by the male, usually within a capacious pouch formed from two folds of skin on the ventral surface of the tail-region. One of the commonest British species is the Great Pipe-fish (*Syngnathus acus*), which is sometimes found in deep water, and sometimes at low tide among the seaweed in rock-pools. The specimens commonly seen are from 1 foot to 18 inches in length. It may be seen slowly moving about, with curious contortions, poking its long snout into every crevice in search of food, and sometimes assuming a vertical position with the head downwards, boring into or stirring the sand.



Pipe-fish (*Syngnathus acus*).

One of the commonest American pipe-fish is *Siphonostoma peckii*, which lives among the eel-grass of the coast.

The name Pipe-fish is sometimes given also to the fishes forming the family Fistularidæ, or Flute-mouths, of which one of the most remarkable is the Tobacco-pipe-fish (*Fistularia tabaccaria*). But these are large marine sticklebacks, and have only a superficial resemblance to the true pipe-fish.

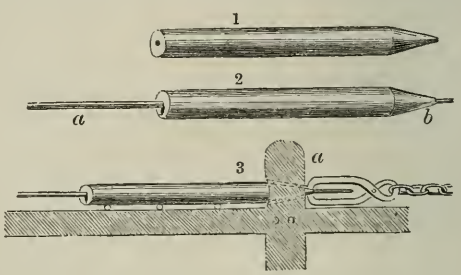
Piperaceæ, a natural order of exogenous plants, natives almost exclusively of the hottest parts of the globe, particularly of Asia and America. About 600 species are known, to most of which the name Pepper (q.v.) is sometimes given, although some are also known by other names, particularly those of which the fruit is not used as a spice, but of which some part is employed for some other purpose, as Betel, Cubebs, Matico, and Ava.

Piperine, an Alkaloid (q.v.) found in pepper.

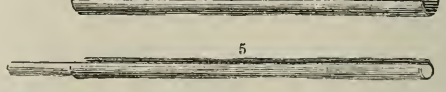
Pipe-rolls. See RECORDS.

Pipes are made of various materials and for various purposes. Thus, we have draining-pipes for agricultural and sanitary purposes, made of earthenware, wood, and metal (see DRAINAGE, SEWAGE), pipes of various kinds of metals for a great variety of purposes, and Tobacco-pipes (q.v.) of various materials. Earthenware pipes are now made of almost every size, from an inch or two in diameter up to the enormous size of 54 inches. They are usually made of fireclay, and are glazed like common Pottery (q.v.). Caoutchouc vulcanised and gutta-percha are also extensively used for making pipes. Leathern pipes are used chiefly for the conveyance of water temporarily, as in the case of fire-engines (see FIRE). Metal pipes are made of iron, lead, tin, or an alloy of tin and lead, copper, brass, &c. Iron pipes, as for water and gas, are usually cast, and the manufacture is one of enormous extent. See WATER-SUPPLY.

Pipes of ductile metal, such as brass, copper, and tin, are made by first casting an ingot into the shape shown in fig. 1, with a hole through its length of the same diameter as the bore of the pipe is intended to have. Into this is placed an iron rod, called the mandrel (*a*, fig. 2), which exactly fits, and which projects slightly at the tapered end (*b*, fig. 2). It is then brought to the drawing-table, and here the small end with its projecting mandrel is put into a funnel-shaped hole, drilled through a steel post (*a*, fig. 3), so as to allow the point to be



gripped on the other side by a pair of pincers, at the end of a strong chain; the machine-power is then applied to the other end of the chain, and the soft metal and its mandrel are drawn through, the former being extended equally over the surface of the latter, which is then removed, and the length of pipe is complete. Some metals require repeated drawing through holes, getting gradually smaller, and have to be softened or annealed at intervals, as the metal hardens under repeated drawing. In this way brass, copper, tin, and pewter pipes are made; and a patent has also been taken out for making steel pipes; but lead pipes are made of great lengths by squeezing the soft metal through a hole in a steel plate in which there is a fixed core or mandrel projecting, which forms and regulates the size of the bore of the pipe. Pipes are also made from copper, brass, and malleable iron by

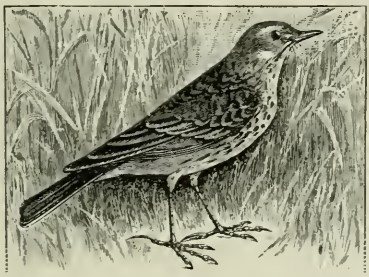


rolling out narrow strips of metal, and then passing them successively through rollers, which are deeply grooved, and which turn up the edges (fig. 4). A mandrel is then laid in it, as in fig. 5, and it is next passed through double-grooved rollers, which turn the edges in, and thus form a complete tube round the mandrel. The edges, however, require hard soldering—i.e. soldering with a fusible brass alloy, or welding, if of iron. All boiler-tubes used to be made in this way; but the method of drawing has lately been so much improved that copper and brass pipes, or tubes, as they are frequently called, are now drawn of considerable thickness and diameter.

Pipi, the name given to the ripe pods of *Cæsalpinia Papai* (see CÆSALPINIA), which are used in tanning, and are not unfrequently imported along with Dividivi (q.v.).

Piping Crow, a name somewhat loosely applied in Australia to any bird of the genus Gymnorhina or Barita (q.v.). Another modification of the name is Piping Crow Shrike or Piping Roller; the bird is also called *Caruek*.

Pipit (*Anthus*), a genus of small birds forming with the wagtails the family Motacillidæ. The pipits have a strong resemblance to the larks in external appearance, and even in many of their habits, such as singing while on the wing; but they moult twice a year, while larks moult only once. With the wagtails they agree in all respects except in colour, and like them they are chiefly terrestrial in habit, running along the ground, working in and out among grass or heather in search of the insects, worms and slugs which



Meadow-pipit (*Anthus pratensis*).

form their food. The Meadow-pipit (*A. pratensis*), also known as the Titlark or Moss-cheeper, is the species most abundant in Britain. It breeds early in spring, nesting in a hollow on the ground or under a bank, and rears two broods in a season. The Tree-pipit (*A. trivialis*), though only a summer visitor, is common in many districts, and breeds freely in the south and west of Scotland. The Rock-pipit (*A. obscurus*) frequents rocky shores and feeds on molluscs and small crustaceans.

Pippi. See GIULIO ROMANO.

Pippin. See PEPIN.

Pippin, a name given to many varieties of apple, among which are some of the finest in cultivation, as the *Golden Pippin, Ribston Pippin*, &c.

Piqua, a city of Ohio, on the Miami River (here crossed by two bridges), 28 miles by rail N. of Dayton. It has foundries, oil-refineries, and manufactories of flour, furniture, mattresses, &c. Pop. (1890) 9090.

Piquet, a game at cards for two players, played with thirty-two cards, the sixes, fives, fours, threes, and twos being rejected. The game was formerly played a hundred up, a *partie* being the best of five games; but about 1880 the rubicon game superseded piquet *au cent*. At the rubicon game six hands are played, each player dealing alternately. The one whose aggregate score is the higher wins the partie. He deducts the loser's score, and adds a hundred to the difference. If the loser fails to score a hundred in the six hands, he is *rubiconed*, and the scores are added instead of being deducted. For a description of the mode of play, handbooks should be consulted.

The earliest known mention of piquet is by Rabelais in the Gargantuan list of games (1530–45). Hence it has been concluded that piquet is of French origin. But it is more probable that a similar game, called *ronfa*, was played in Italy at an earlier date, and that this game, with modifications, travelled from Italy to Spain, where it was re-named *cientos*, and to France, where it was re-named *piquet*. Piquet seldom, if ever, occurs in English books of the Shakespearian period, but *cent* (*cientos*) frequently does. From this it may be concluded that piquet, under the name of cent, was played in England until about the middle of the 17th century, when the word 'cent' went out of use, and was replaced by the word 'piquet.' It may be noticed in this connection that from the time of the marriage of Mary to Philip of Spain (1554) the English equivalent of the Spanish name of the game was in vogue, and that contemporaneously with the marriage of Charles I. to the daughter of Henry IV. of France (1625) the French name *piquet* was substituted.

The etymology of piquet has been much speculated on; no satisfactory settlement has been arrived at. In 1651 was published *The Royall and Delightfull Game of Piequet*, translated from the earliest known French book on the subject. This was followed by several others, more or less resembling it, *Wit's Interpreter* (1671), Cotton's *Compleat Gamester* (1674), and Seymour's *Court Gamester* (1719), all containing piquet. The next original work was Hoyle's *Short Treatise on the Game of Piquet* (1744). This included the laws which were the authority until 1873, when the Portland Club issued a code. The general adoption of the rubicon game, shortly afterwards, necessitated a fresh revision; and in 1881 the Portland and Turf Clubs agreed to the code of laws which now governs the game. These laws were published in 1882, together with a treatise on the game, by 'Cavendish.'

Piracy (Lat. *pirata*; Gr. *peiratēs*, 'an adventurer,' 'a pirate'), robbery on the high sea, was apparently very much mixed up with early maritime adventure, the sea-rover being frequently pirate as much as trader: thus, the Phœnicians often combined piracy with more legitimate seafaring enterprise. In Homeric times piracy was accounted a reputable or even dignified calling; and the Greeks, especially the Phocæans, long displayed a natural genius for piracy. This aptitude was cherished by the constant warfare between small states, it being difficult sometimes to decide what was public and what was private war. Cilicia was long the headquarters of Mediterranean piracy, until in 67 B.C. Pompey made his memorable expedition against the pirates with great naval and military forces. From the 8th to the 11th century the Norse vikings were the terror of western coasts and waters (see NORTHMEN). The Hanseatic League (q.v.) had its origin in the desire for mutual defence against Baltic and other pirates. At a later date the Moslem rovers scourged the Mediterranean, commingling naval war on the large scale with peddling, thievery, and the abduction of slaves: Algiers was a piratical stronghold till well into the 19th century (see CORSAIRS); and in the 17th century the English Channel swarmed with Algerine pirates, who snapped up in one prize £500 worth of linen belonging to the Lord Deputy of Ireland, and blockaded him, the king's representative, for weeks in an English port while he waited for a ship-of-war to convey him across the Irish Sea. In 1635 they actually entered Cork harbour, and carried off a boat with eight fishermen, to be sold as slaves in Algiers. The Buccaneers (q.v.) preyed mainly on the Spanish commerce with the Spanish American colonies. Lundy Island (q.v.) was long a nest of pirates, English and other. Captain Kidd (q.v.) is in the popular mind the chief representative of the picturesque type of pirates, whose career of reckless bloodshed and rapine under their 'Jolly Roger' or

black flag, alternating with luxurious debauchery, has come to be surrounded with a halo of romance, reflected in E. A. Poe's *Gold Bug* and R. L. Stevenson's *Treasure Island*. The prototype of Scott's *Pirate* was John Gow, who in January 1725 boldly anchored in Orcadian waters, and entered into friendly relations with the islanders, till, recognised as an atrocious villain, he was with his crew captured and carried to London to be tried. He and eleven of his comrades were condemned a month or two after, and the pirate captain and nine of his men were executed together. So late as 1864 five men were hanged in London for murder and piracy. National prejudices tend to obscure the distinction between Privateering (q.v.) and piracy: Paul Jones was called a pirate in England, and the commanders of the Confederate ships *Alabama*, *Shenandoah*, and *Florida*, which preyed on northern commerce, were in northern eyes practically pirates. Of late the pirates tried by admiralty courts are rather naval mutineers than pirates in the old sense. The African slave-trade was not considered piracy by the law of nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and in or after 1841 it was declared to be so by Austria, Prussia, and Russia. The home of professional piracy, happily now on a small scale, is the Malay Archipelago and the China Seas; Sea-Dyaks and Malays disputing with Chinamen the palm of hardihood as sea-robbers.

Piracy is recognised as an offence against the law of nations. It is a crime not against any particular state, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas. It is of the essence of piracy that the pirate has no commission from a sovereign state, or from one belligerent state at war with another. Pirates being the common enemies of all mankind, and all nations having an equal interest in their apprehension and punishment, they may be lawfully captured on the high seas by the armed vessels of any particular state, and brought within its territorial jurisdiction for trial in its tribunals; but it is not permitted to put pirates to death without trial save in battle.

The infringement of the Copyright Acts is often spoken of as literary piracy; and the word is not unfairly extended to cover the case in which the publishers of one nation issue unauthorised reprints by authors of another nation—especially the case of American reprints of English works (see BOOK-TRADE, Vol. II. p. 316). Thus, several pirated reprints of the first edition of this Encyclopædia were issued and were being sold in 1890, in which obsolete facts and statistics twenty years old were reproduced with marvellous fidelity.

Piræus (Gr. *Peiraieus*), called also PORT DRACO, the harbour of both ancient and modern Athens (q.v.). Planned by Themistocles and laid out by Hippodamus of Miletus, the Piræus was built in the glorious days of Pericles; this ruler and Cimon before him built the three 'long walls' that connected Athens with its port (5 miles to the south-west), and so ensured a free and safe passage from one to the other at all times. It was both a war harbour and a commercial port, many foreigners living within its walls. Its arsenal (built 347–323 B.C.) and fortifications were destroyed by Sulla in 86 B.C., and from that time the town sank into decay. The modern Piræus, which has grown up since 1834, is a regularly laid-out but mean-looking town, with a naval and a military school, arsenal depôts, and manufactures of cottons, flour, paper, iron, nails, carts, furniture, &c., and is growing rapidly. A railway (1869), 5½ miles long, connects it with Athens. The foreign trade (£4,000,000 annually) is half that of all Greece. The imports are mainly coal and railway plant, &c., from Britain, petroleum from the United States, and sheep and cattle from Russia; and the exports, tobacco, valonia, hides, bones, horns, cheese, wool, &c. A total of 6000 vessels of 2½ million tons enter annually, one-half the tonnage being in Greek bottoms. Pop. (1871) 11,000; (1879) 21,055; (1890) 36,000.

Pirano, a seaport of Austria, on a promontory on the south side of the Gulf of Trieste and 12 miles SW. of the city of Trieste. It has two harbours, an old castle, and manufactures of soap, glass, &c., with neighbouring salt-works. Pop. 9419.

Pirkheimer. See DÜRER.

Pirmasens, a town of the Bavarian Palatinate, and formerly the chief town of the county of Hanau-Lichtenberg, 34 miles by rail W. of Landau. The chief manufactures are shoes and musical instruments. Close by the Prussians under the Duke of Brunswick defeated the French commanded by Moreau on 14th September 1793. Pop. (1885) 14,938; (1895) 24,548.

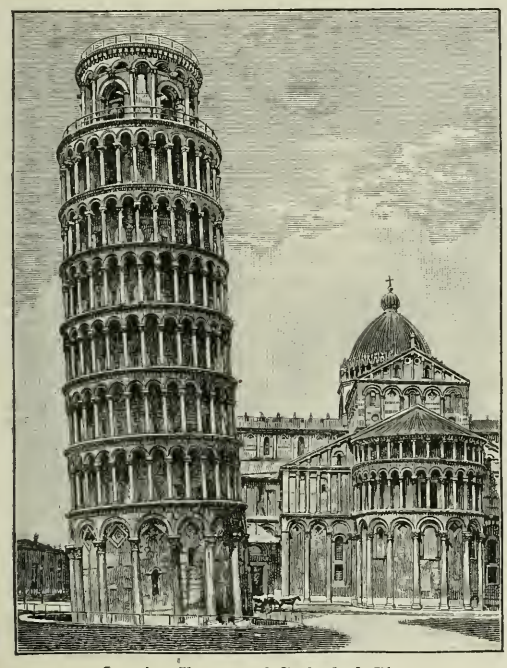
Pirna, a town of Saxony, stands on the left bank of the Elbe, 11 miles by rail SE. of Dresden. Here are a fine 16th-century church; a castle (1573), used as a lunatic asylum since 1811; and manufactures of glass, chemicals, tobacco, stoves, &c. Eight thousand men are employed in the sandstone-quarries. Pop. 15,670.

Pirogue. See PERIAGUA.

Pirot, a town of Servia, on the Nischava, 30 miles ESE. of Nisch. It was occupied by Servian troops in 1877, and taken by the Bulgarians in 1885. Pop. 8832.

Pisa, one of the oldest cities of Italy, the rival of Venice and Genoa, which still has its walls standing and a citadel, is situated on the Arno, by rail 49 miles W. of Florence and 13 NE. of Leghorn. It was formerly a great port, though six miles from the sea, but owing to the silting-up of the river is now quite inaccessible to ships. Its commerce has been transferred to Leghorn. It is still a city of fine buildings, foremost amongst which is the cathedral (1063–1118), with a noble dome, fine paintings by Cimabue, Andrea del Sarto, and others, and beautiful marble altars. Its shape is that of a Latin cross, 311 feet long by 252 wide; the nave is 109 feet high. Externally it has a magnificent façade of four superimposed rows of pilasters and arches, and fine bronze doors by Giovanni da Bologna and others. Near the cathedral stands the round marble campanile, the 'Leaning Tower of Pisa,' which is a magnificent specimen of the southern Romanesque architecture, but is peculiar in that it (including the cornice) deviates about 14 feet from the perpendicular. This peculiarity is not due to original design. The tower seems to have begun to heel over to one side when the third story was completed; the architects deliberately accepted the conditions, and adhered to the inclining position, but diminished the slope of the upper stories so as to keep the centre of gravity well within the walls. (There are two leaning towers also at Bologna, q.v.) The tower is 180 feet in height, consists of eight stories divided by rows of columns, the last, which contains the bells, being smaller in diameter than the others. The tower was erected in 1174 and succeeding years by the architects Bonanno of Pisa and William of Innsbruck; but the eighth story was not completed till the middle of the 14th century. The marble Baptistery, or Church of St John (1152–1278), opposite the cathedral, is circular, and

supports a dome, crowned with a cupola. The interior, noted for its wonderful echo, contains the grand and elaborate pulpit of Niccola Pisano (1260) and a large marble font. The beginning of the Campo Santo, or ancient national cemetery, was several loads of earth brought from Jerusalem towards 1200. In 1278–83 the ground was surrounded by cloisters by Giovanni Pisano, the walls of which were adorned with fresco-paintings by Orcagna, Benozzo Gozzoli, and others. The city contains



Leaning Tower and Cathedral, Pisa.

numerous other churches, some of great age, dating from the 13th century and even earlier; also many fine palaces, private and official residences, including that of the archbishop. The university (1338) has a natural history museum, a botanical garden, a library (1742) of 120,000 volumes, and sixty lecturers and 600 students. The town possesses an academy of fine arts and archives. Amongst distinguished natives may be named the popes Eugenius III. and Nicholas V., the Visconti, Peter the Deacon, Leonardo the mathematician, Giovanni (but not Niccola) Pisano, and Galilei. The industrial activity is now confined to cottons, silks, ribbons, and the working of coral and alabaster. Dromedaries are bred at a royal farm in the neighbourhood. Pop. of commune (1881) 53,957; (1896) 64,700. The province has an area of 1180 sq. m. and (1896) a pop. of 311,742.

History.—Ancient Pisa, originally an Etruscan city, became subject to Rome in the 2d century B.C.; but, on the decline of the western empire, it was compelled to submit in turn to the nations who successively overran Northern Italy. Early in the 11th century Pisa had developed into a powerful republic, possessing a formidable fleet and extensive territories along the Tyrrhenian Sea; it yielded little more than nominal homage to its suzerain lords, the emperors of Germany. Throughout the 11th century Pisa was at the height of its prosperity; to this period belong most of the splendid monuments of art that still adorn the city. It had extensive commercial relations with the East; its 'customs of the sea' (1075) were the pattern upon which the sea-laws of nearly all peoples navigating the Mediterranean were modelled. During the same century the Pisans repulsed the Saracens (1011), took Sardinia from them in 1022, attacked them in Africa in 1030, and routed them utterly off Palermo in 1062. Early in the next century, in 1114–16, they wrested the Balearic Isles from the same enemies. In the second crusade too they played a prominent part, and helped the pope against the Normans, taking Amalfi in 1135 and again in 1137. But already in the 11th century the rivalry between Pisa and Genoa had broken out. Florence too, a Guelph city, grew into an enemy of the Ghibelline Pisa. Wars many and often were waged between Pisa on the one side and a coalition of cities, headed by Florence and Genoa, on the other, with varying fortune, until in 1284 the Pisan fleet was crushed at Meloria. After this Pisa was compelled to give up Corsica, part of Sardinia, and 160,000 gold pieces to Genoa. At the same time Ugolino (q.v.) della Gherardesca made himself master of the town. Various individual rulers or tyrants followed, until the Pisans finally threw themselves (1399) under the protection of Galeazzo Visconti of Milan. The son of the latter sold the Pisan territory to their greatest enemies, the Florentines, from whose tyrannical rule they were for a time relieved by Charles VIII. of France, who, in 1494, accepted the protectorate of the city. When the French left Italy the old struggle was renewed; and, after a desperate resistance, the Pisans, in 1509, were compelled by hunger to surrender to the Florentine army. The most influential families, as formerly in 1406, emigrated. From this time Pisa steadily declined, until in the middle of the 16th century it had less than 8600 inhabitants. Its history henceforth coincides with that of Tuscany (q.v.). With the rest of Tuscany it became part of the kingdom of Italy in 1860.

The Council of Pisa met in Pisa on March 25, 1409, and of which the twenty-third and last session was held on 7th August following. Its aim was to end the schism which had divided the Western Church for thirty years, and with this view the leading cardinals, finding that neither of the rival popes, Gregory XII. and Benedict XIII., would keep their promises to abdicate, set aside the claims of both, and themselves convoked a general council. It was attended from first to last by 24 cardinals, 4 patriarchs, 80 bishops, 102 proctors of bishops, 87 abbots, 200 delegates of abbots, besides many generals of orders, doctors, deputies of universities, and ambassadors. After the rival popes failed to appear in obedience to its summons, the council formally tried the claims of both in turn, and deposed them as schismatics and heretics. The cardinals then formed themselves into conclave and elected Cardinal Philargi, who assumed the name of Alexander V. But the council, instead of getting rid of the contending popes, had only added a third, and the faithful continued to be distracted in their allegiance for eight years longer, down to the time of the Council of Constance. Bellarmine considers the Council of Pisa as 'neither clearly approved nor clearly rejected;' Hefele says 'neither ecclesiastical authority nor the most trustworthy theologians have ever numbered it among the ecumenical councils.' See Hefele's *Conciliengeschichte*, vol. vi.

Pisagua, a small port of the now Chilian province of Tarapacá, 40 miles N. of Iquique by rail; pop. 2131. It was bombarded and was the scene of much fighting during the Chilian civil war in 1891.

Pisano, Niccola, a distinguished sculptor of Pisa, was born, apparently near Lucca, about 1206.

His earliest work is supposed to be the 'Deposition' over one of the doors of the cathedral at Lucca, dated 1237. His reputation is supported by three important works, which are still admired for their excellence—the pulpit of the baptistery at Pisa (1260), the 'Arca' or shrine of St Dominic for the church of that saint at Bologna (1267), and the pulpit of the cathedral at Siena (1268). He died at Pisa in 1278, and was buried in the Campo-Santo. He was also a great architect and a skilful engineer. His influence on art was wide, reviving the love of beauty and giving new birth to the plastic arts. His pupils Arnolfo and Lapo executed numerous works at Rome, Siena, and other cities. His son and heir in reputation, GIOVANNI PISANO (1250–1330), was not his equal either as sculptor or as architect. Niccola's pupil Andrea de Pontedera, generally called ANDREA PISANO (1270–1349), was first a goldsmith, but became famous as a worker in bronze and a sculptor in marble. He settled in Florence, and his best work there (one of the baptistery doors and many sculptures on the Campanile) shows strong traces of Giotto's influence. Vittore Pisano, or Pisanello (1380–1456), was both fresco-painter and medallist. See Crowe and Cavalcaselle, *Painting in Italy* (1864); Symond's *Renaissance in Italy* (1886); Leader Scott, *Early Italian Sculptors* (1882).

Piscat'aqua, a river which constitutes part of the boundary between Maine and New Hampshire, and forms at its mouth the excellent harbour of Portsmouth. See NEW HAMPSHIRE.

Pisciculture. Fish-culture is the art of increasing the supply of food-fishes—first, by breeding and rearing them artificially; secondly, by protecting the gravid fish and the natural spawning and nursery grounds through legislation; thirdly, by creating new breeding-grounds through the removal of obstructions or the placing of fascines, stakes, tiles, &c. for the collection of ova or of spat; lastly, by increasing the amount of natural food in any practicable manner. In recent years the artificial culture of sea-fish has been attempted on a large scale in several countries. In the United States and in Norway fully-equipped hatcheries for sea-fish and shellfish have been in operation for a number of years. In 1889 the Newfoundland government erected a marine hatchery at Dildo, Trinity Bay; and a similar establishment was completed in 1891 by the Canadian government near Pictou, on the Northumberland Strait, Nova Scotia. In 1890 the Newfoundland hatchery turned out over fifteen millions of cod fry and four hundred millions of young lobsters. In Britain the hatching of sea-fish has not yet been undertaken on a large scale; but very excellent experimental work has been done at Plymouth by Mr J. T. Cunningham, who succeeded in artificially fertilising and hatching the eggs of the common sole in the early part of 1890; at St Andrews by Professor M'Intosh; and by the Fishery Board for Scotland at Dunbar. Under the second head the Fishery Board for Scotland entered in 1883 on a series of experiments to ascertain what legislation, if any, was required to protect the inshore waters either as spawning, nursery, or food-producing grounds, and several bylaws have been passed protecting the greater portion of the Scottish inshore waters. These provisions were extended by the Herring-fishery (Scotland) Amendment Act, 1889.

Ponds for fresh-water fishes have been common from a very remote antiquity. It appears from Isaiah, xix. 10, that they were used in ancient Egypt. In the times of Roman luxury almost every wealthy citizen had fish-ponds. The Chinese have long bestowed more attention on pisciculture than any other nation, and with them it is truly a branch of economy, keeping up the supply of food, fish being used as much as meat by rich and poor at every meal. In China a large proportion of fish for the markets of the interior are reared in ponds. Some of these are generally placed in front of the villages, and in some places large numbers of them spread over plains. A common way of rearing in that country is to keep a number of male and female fish in small ponds so as to furnish eggs. After these are hatched, and the young fish become two or three inches in length, they are transferred to larger ponds. At the end of six or eight months they are caught and sent to market. Carp, perch, tench, and bream are some of the kinds kept in ponds. In some countries of modern Europe this branch of pisciculture is also prosecuted to a very considerable extent, particularly in Germany and Sweden, and of late years in France, in order to increase the supply of fish for the market. In Britain it has only recently been systematically prosecuted. The country-seats of the nobility and gentry have, indeed, been generally provided with fish-ponds, but in most cases rather as ornamental waters than for use. In the northern parts of Britain trout, perch, and pike are almost the only fish kept in ponds; in England they are often stocked with carp and tench, and are turned to much better account than in Scotland. In Germany ponds carefully attended to are found very productive and remunerative. There can be no doubt that in Britain also many a piece of land at present very worthless might easily be converted into a pond, and made to yield large quantities of excellent fish.

The greatest improvement in pisciculture, and a most important branch of it, to which the term is often restricted, is the breeding of fish in artificial breeding-places, from which not only ponds but rivers may be stocked; or the art of fecundating and hatching fish-eggs, and feeding and protecting the young animals till they are of an age to secure their own food and protect themselves from their numerous enemies.

In the middle ages, and especially in the 14th century, fish-ponds were common in the domains of princes and nobles and religious communities; but these were used only for rearing purposes. The first attempt at artificial fertilisation of fish eggs appears to have been made at the beginning of the 15th century, by Dom Pinchon, a French monk; but his experiments attracted no attention. Between 1725 and 1765 Stephan Ludwig Jacobi of Hohenhausen, Lippe-Detmold, bred trout artificially; but commercial pisciculture owes its origin to the French, the art having been first practised by Rémy, a poor fisherman who worked the streams of La Bresse in the Vosges. It was the great waste of eggs incidental to the natural system of fish-breeding that led Rémy about 1842 in conjunction with a partner, Géhin, to try to repeople the fish-streams of his native district. His plan, being successful, attracted the notice of many of the French savants, and led to preferment for Rémy; the new art was besides taken up by the government. At Hüningen in Alsace, on the Rhine, a gigantic fish-nursery and egg-depôt was erected in 1852, chiefly through the energy of M. Coste. Since the cession of Alsace to Germany the operations of the establishment at Hüningen have been conducted on a still larger scale by a German association.

Rémy and Géhin's plan of rearing trout artificially is this: At the time the female is about to spawn she is caught and gently pressed on the abdomen by the hand, when the ova or eggs spurt forth into a vessel containing water. In the same way the milt is taken from the male. The eggs

are well mixed with the milt, and the water changed once or twice. The fecundation being completed, the next thing is to place the eggs for security into a covered vessel. Its early form was that of a flat, round box about eight inches in diameter, with a hinged lid. This was made of zinc, perforated with small holes, and had a layer of fine gravel on the bottom. A considerable number of fecundated eggs were enclosed in the box, which was then placed in the bed of a current of pure water and covered with pebbles, care being taken that the water passed freely through, as it is necessary for the eggs to be slightly agitated. The hatching takes place in from two to four months, the time depending on the nature of the water and other circumstances. For a description of the early changes which the fish undergoes, see SALMON. After the little fish are fully formed they are kept in the box from eight to fifteen days, and then set at liberty. The later plans for artificially propagating trout or salmon differ principally in mixing the ova and milt in an absolutely dry utensil and in the details of the hatching-boxes, in the use of houses, and in many of the young fry being kept in ponds till they are a year or more old.

The most sustained effort in British pisciculture has been in connection with the salmon-fisheries of the river Tay. At Stormontfield, near Perth, since 1853, a series of open-air breeding-boxes, covered with gravel and capable of receiving 500,000 eggs, have been in use; but for years nothing like this number have been hatched, and probably not 20,000 young fish annually have for some time past been turned out of the ponds there. The Tay District Fishery Board in 1883 erected a new hatchery a few miles away at Dupplin on the Earn. It was put up to try the system of glass grill hatching-boxes, designed prior to 1860 by M. Coste of Paris, and presently to be described as in use at Howietoun. On this plan it was estimated to hatch 300,000 ova. But in the autumn of 1883 the Board decided to adopt only partially the grill hatching, and to try along with it the simpler Canadian system of shallow trays of perforated tinplate, and coated with Japan varnish; in which the eggs, instead of being in separate rows, are packed very closely together, river-water being used. In 1889 it was stated to be capable of hatching four or five hundred thousand fish.

The most extensive fish-rearing establishment in Great Britain is the one belonging to Sir James Maitland, situated at Howietoun, near Stirling. It consists of hatching-houses and, at a distance from them of half a mile, an extensive series of ponds. The principal hatchery is 86 feet long by 40 feet wide, each of its two stories being 10 feet high. Its walls, built of brick and concrete, are nearly 2 feet thick; and the roof is covered with a layer of concrete 3 inches thick, over which there is a thin cover of asphalt. The entire outer shell is thus a bad conductor of heat, so that it is not difficult to keep the water inside from falling below 44° F. Fig. 2 gives a sectional view of the hatchery. It will be seen that each floor has a considerable slope, which admits of the hatching or grill boxes (*a*, *a*, *a*, *a*, fig. 2) being placed in descending series. These are 134 in number, the ordinary size of them being 6 feet 9 inches long, by 1 foot 7 inches broad. In the bottom of each box four wooden frames are neatly fitted, each of which has rather more than 100 glass tubes, about ¼-inch in diameter, placed transversely. Fig. 1 shows a longitudinal section

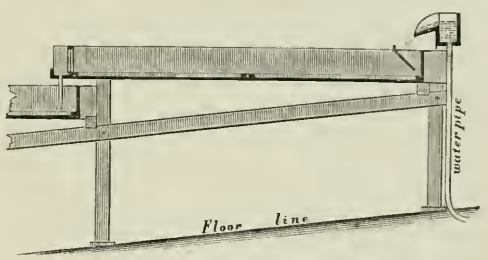


Fig. 1.

of one of these hatching-boxes, in which the dotted line indicates the position of the glass tubes. Upon these glass grills the fish-eggs lie in parallel rows,

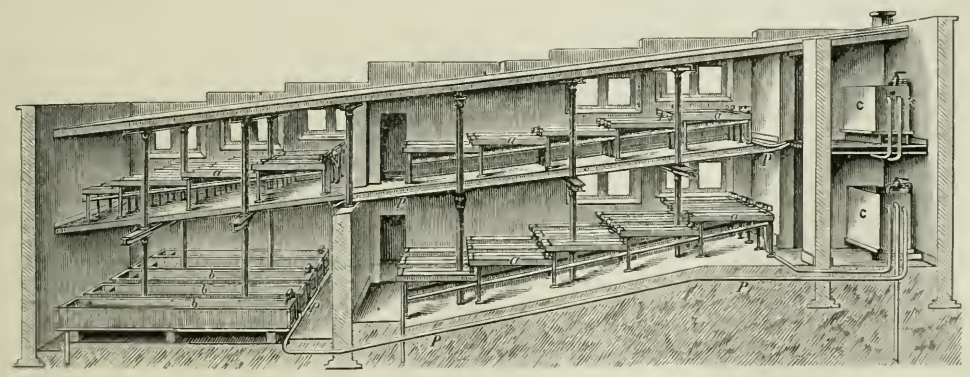

Fig. 2.

looking like small pink beads. Six cisterns or tanks (*b*, *b*, *b*), each 20 feet long and five feet broad, are fitted up in the lower portion of the ground-floor to receive the young fry after they begin to take food. At Howietoun both hatching-boxes and rearing-tanks are constructed of wood charred on the internal surfaces, and painted on the outside, their ends being formed of perforated zinc, which is closed with flannel when any depth of water is required in the tanks. At other hatcheries, however, the tanks and boxes are formed of slate, and sometimes of earthenware, but in such cases they are of smaller size. Often, too, the eggs are placed on perforated zinc or porous earthenware instead of glass grills. While the eggs are being hatched only spring water is used. It is brought underground to the two cisterns (*c*, *c*), and from these it is conveyed by lead pipes (*p*, *p*, *p*, *p*) to each series of hatching-boxes, over the grills of which it flows in a constant but not rapid stream. Each of the hatching-boxes contains about 15,000 eggs, but in the earlier part of the hatching-season (December) eggs are also placed in the 20-feet tanks, so that about four millions of

fish-eggs can be brought to maturity in one season. In 1890–91, 2,310,000 eggs were incubated, 81,500 yearling trout sold and 40,000 yearling trout retained, to grow into two-year-olds, and 19,000 two-year-old trout sold and 6000 retained.

The ponds at Howietoun are extensive and ingeniously planned, both for beauty and convenience. Water is supplied to them from a burn issuing from Loch Coulter, a lake of considerable size, and largely fed by springs. They are divided into a larger and a smaller group. The former consists of ten ponds, of which the largest measures 200 feet in length by 90 feet in width, and is 12 feet deep. Next to this is a sub-group of three ponds lying parallel to each other, each 270 feet by 45 feet, and 10 feet deep. These also contain Lochleven trout of different ages, and about 5000 in number in each pond. The remaining twenty-five ponds are each about 100 feet long, and contain respectively American brook trout (*Salmo fontinalis*), yellow trout (*Salmo fario*), and more Lochleven trout under three years of age. Their various levels are so arranged that by means of open tracts and dividing-boxes the water is slowly but constantly flowing from the highest to the lowest pond in the series, and sluices are provided so that any single one can be emptied when required. Each pond is also provided with a cleansing pipe.

At Howietoun the young fry are fed chiefly on grated eggs and beefsteaks made up into strings like vermicelli, yearlings and two-year-olds are fed on minced horse-flesh, and older trout on shellfish. But some pisciculturists strongly recommend that additional kinds of food, such as boiled liver, chopped worms, fish-roe, and biscuit-dust, should be given in turns to fry. A large proportion of trout die—many, as some experienced persons think, of starvation—during their first year, even when kept in ponds regularly supplied with food. The strong repel and devour the weak at feeding-time, but the mortality, in so far as it may be caused by food at all, is probably more due to the kind used, or to the form in which it is given. In the case of rearing-ponds situated near the sea, mussels and shrimps are much used for feeding purposes. At Guildford, Surrey, the trout are allowed to find their own food, but with this system the ponds must be large in proportion to the number of fish contained in them, as well as favourably situated with respect to a sufficiency of natural food. Near St Pölten, Lower Austria, this plan is adopted. There are a number of small ponds or ditches with stagnant water and aquatic plants, which are used as nurseries to propagate the larvæ of insects, small crustaceans, and other low forms of animal life on which trout naturally feed. From time to time part of the water swarming with these creatures is admitted to adjoining ponds with pure water in which the fish live. It probably depends on the locality of the ponds which method of feeding succeeds best in a commercial sense.

In Great Britain it is as yet only members of the Salmonidæ family which have been artificially reared on a commercial scale. But quite recently some attention has been given to the cultivation of what are called 'coarse' fresh-water fish. By this is meant pike, perch, roach, carp, tench, and a few others. Of these pike and perch are perhaps the two most likely to be profitable. It is feared, however, that so long as the markets are fairly well supplied with sea-fish, salmon, and trout the chance of these coarse fish being largely consumed as food is not great. They have all, more or less, a comparatively insipid taste, but this could no doubt be improved by proper attention to their food. Pike being great cannibals, there is more difficulty in stocking ponds with them, even when there is not much difference in their size, than with most other fish. Perch—which have an extraordinary power of increase—spawn readily in confinement, but it is said that the fry are not very easily reared. In America persevering efforts are being made to acclimatise the mirror carp, which is a favourite fish for the table in Germany. See PIKE, PERCH, and CARP.

Pisciculture is practised in America on a very large scale. The United States Fish Commission have several stations for hatching eggs of the Salmonidæ, the largest being on the M'Leod River, California, established for the ova of the California salmon (*Salmo quinnat*). The report of the commissioner, Professor Spencer Baird, gives the total production of eggs at this station for the season of 1879 as about 9,500,000; but the number for 1878 was 14,000,000. In 1879, 2,300,000 were hatched at the station to keep up the stock in the Sacramento River, 4,150,000 were taken to the eastern states, and the remainder were sent to Canada, France, Germany, and Holland. The Californian salmon can adapt itself better than the common species to comparatively warm water, so that it will thrive in some rivers where the latter will not; but whether it will be successfully introduced into Europe is still a matter of uncertainty. This station is now chiefly used for hatching the rainbow trout (*Salmo irideus*), 28,700 fry being planted in the M'Leod River in 1885. There is another hatching-station at Bucksport, Maine, for the Atlantic salmon (*Salmo salar*); and a third at Grand Lake Stream, Maine, for breeding the Schoodic or landlocked salmon, which is a variety of the *Salmo salar*. In the United States there are several hatcheries for the propagation of shad, the aggregate yield of which in 1885 was 38,000,000 young fish. As regards numbers, however, both salmon and shad sink into insignificance compared with the quantity of white fish, of which the most important species is *Coregonus clupeiformis*, reared in the piscicultural establishments of the Lake States (see COREGONUS). The production of eggs of this fish in the year 1885 reached the grand total of 268,000,000. Besides the hatcheries under the direction of the Fish Commission, most of the states have hatcheries of their own. In 1890 those belonging to the state of New York alone distributed 39,930,000 fry and eggs of trout, shad, pike, &c.; the station at Caledonia, in that state, has distributed 18,000,000 trout, salmon-trout, carp, pike, and muscalongue in one year. Hatching-stations for the cod and other sea-fish are also being tried. For oyster-culture, see OYSTER.

Canada is not far behind the United States with respect to the scale of her fish-breeding establishments. The principal ones—twelve in number—are owned by the government, and their production for the year 1889 amounted to 11,673,500 salmon-eggs, 5,140,000 salmon-trout eggs, 30,600,000 eggs of white fish (*Coregonus albus*), and 21,000,000 eggs of members of the Percidæ family, besides smaller numbers of other species, making a total of 68,700,000. The common or Atlantic salmon has been introduced into Tasmania, and seems now to be thoroughly acclimatised, numbers of adult fish, besides shoals of the young, occurring in the rivers. One or more species of British trout have also become established in Tasmanian as well as in Australian and New Zealand rivers. At Otago there is a trout-hatchery. In Victoria the Californian salmon has been found to succeed better than the common species.

See works on Pisciculture or departments of the subject by Armistead (1870), Andrews (on salmon and trout, 1886), Ashworth (on Stormontfield, 1875), Atkins (fittings for salmon-culture, Washington, 1879), Boccius (1841 and 1848), Buckland (1863 and in *Nat. Hist. of Brit. Fishes*, 1880), Burgess (1891), Capel (on trout, 1877),

Piscina (named from the swimming-pond in the old Roman baths), in Catholic churches, a shallow stone basin with a drain usually leading directly to the earth, in which the priest washes his hands, and rinses the chalice at the end of the celebration of mass. In England it is almost invariably placed on the south side of the choir, at a convenient height.

Piscina.

Pisek, a walled town of Bohemia, stands on an affluent of the Moldau, 84 miles by rail S. by W. of Prague, and has iron and brass works, and manufactures of paper, boots, hats, &c. Pop. 10,596.

Pisgah, a name that seems to have applied generally to the mountain-range or district to the east of the Lower Jordan, identical with, or itself a part of, the mountains of Abarim (Deut. xxxii. 49; xxxiv. 1), one of the summits of which is Mount Nebo (the modern *Neba*), 2644 feet above the level of the Mediterranean. From this point Moses enjoyed his glimpse of the Promised Land, in early spring. It is not the highest point among the spurs which here run out from the Moabite plateau, but Major Conder points out that it is the nearest ridge to the Israelite camp in the plain of Shittim. He describes the view to the east as shut in but two miles off by the shelving edge of the Moabite plateau, and to the south as closed five miles off by a long ridge, but that to the west as including all the Judæan watershed, and in clear weather all Samaria and Lower Galilee, as far as Tabor and the chain of Gilboa. The Sea of Galilee and Hermon are shut out by the lofty range of Pennel (*Jebel Osh'a*) in Gilead, while the western watershed of Judæa and Samaria makes it impossible to see the waters of the Mediterranean; but below to the south-west the northern half of the Dead Sea is seen, bordered by the precipices of Engedi, beyond which stretches the dreary Jeshimon or desert of Judah. The burial-place of Moses is unknown, but may have been, suggests Conder, in the terrible gorge of the Zerka M'aîn, on the south side of the cliff of Peor, or Minyeh, the Callirhoe of the tyrant Herod's days. Its old Hebrew name appears to have been Nehaliel ('the valley of God').

Of the three stations from which Balaam watched the encampment of Israel, Conder makes the first Bamoth-Baal (*Maslubiyeh*), a high ridge separated from Nebo by a deep valley; the second, the ridge of Nebo itself; the third, the top of Peor, over against Jeshimon, a cliff called *Minyeh.*

Pishín, a district of Southern Afghanistan, just north of Quetta, which has been governed by a political agent of the Governor-general of India since 1878. The British occupied it on account of its great strategical importance: it is the meeting-place of several roads, practicable for troops but not for wheeled carriages, leading from Sind and Punjab to Kandahar. The district—area, 3600 sq. m.; elevation, 5000 feet—consists of alluvial valleys separated by ranges of hills, the whole sloping south-west, and surrounded by mountain-chains that reach in north and south 11,000 feet. The people, partly settled, partly nomad, grow wheat, barley, maize, millet, lucerne, water-melons, and musk-melons, and trade in horses to India. Pop. 60,000. A branch of the Indus valley line traverses the principal valley.

Pisidia, one of the ancient divisions of Asia Minor, lay on the south, separated from the sea by the narrow strip of Pamphylia, and having Phrygia on the north, Isauria on the east, and Lycia on the south-west. Traversed by the main chain of the Taurus, it is a mountainous region, with an inhospitable climate. The people, a race of hardy and lawless mountaineers, were greatly given to predatory expeditions, and do not seem to have paid any regular obedience to the various oriental and other conquering races until Roman times. Under the Roman supremacy there were several prosperous cities, as Sagalassus, Antioch, Selge, Termessus. The boundaries of the province varied at different periods.

Pisis'tratus (Gr. *Peisistratos*), a famous 'tyrant' of Athens, was born about 600 B.C. At first he co-operated with his kinsman, the famous Solon, and in the war against the Megarians acquired considerable military distinction; but afterwards, when probably his ambitious views had become more matured, he came forward as the leader of one of the three parties into which Attica was then divided—the *Diacrii* (party of the Highlands), chiefly a labouring population, jealous of the rich, and eager for equality of political privileges. Driving into the market-place of Athens one day, and exhibiting certain self-inflicted wounds, he called upon the people to protect him against his and their enemies; and, a general assembly of the citizens being summoned, a partisan proposed to allow him a bodyguard of fifty men. The measure was carried in spite of the strenuous opposition of Solon. Gradually Pisistratus increased the number, and in 560 B.C., when he felt himself strong enough, seized the Acropolis. The citizens, in general, seem to have tacitly sanctioned this high-handed act. Megacles and the Alcmæonids—the heads of the rich aristocratic party—fled from the city, but returned in 554 and drove Pisistratus into exile in Eubœa (552). Supported by Thebes and Argos, he was able in 541 to sail with a strong force, landed in Attica at Marathon, and marched on the capital. His partisans hurried to swell his ranks. At Pallene he encountered his opponents, and completely defeated them, but used his victory with admirable moderation. When he entered the city no further resistance was made, and he resumed the sovereignty at once. He lived for sixteen years afterwards in undisturbed possession of power, dying 527 B.C., and transmitting his

supremacy to his sons, Hippias and Hipparchus, known as the *Pisistratidæ*. Although the precautionary measures he adopted to establish his authority involved at first a resolute and stringent policy, yet no sooner had he placed himself out of danger than he began to display that wonderful tact, moderation, and sympathetic appreciation of the wishes of the Athenians that have won him the praise and esteem of all later ages. He firmly, but not harshly, enforced obedience to the laws of Solon; emptied the city of its poorest citizens, and made them agriculturists, supplying such as had no resources with cattle and seed; secured provisions for old and disabled soldiers; bestowed great care on the celebration of the religious festivals of the Atticans; encouraged literature more than any Athenian had ever done before—it is to Pisistratus, or to the poets, scholars, and priests about him, that we owe, for example, the first complete edition of Homer; and, like his still more brilliant successor in the following century, Pericles, he adorned Athens with many of its most beautiful buildings, such as the Lyceum, temples to the Pythian Apollo and the Olympian Zeus, &c. See works on Pisistratus by Flach (1885) and Töpffer (1886).

Pisolite (Gr., 'pea-stone'), a concretionary limestone, differing from oolite in having the particles as large as peas.

Pistacia, a genus of trees of the natural order Anacardiaceæ, having diœcious flowers without petals, and a dry drupe with a bony stone. The Pistacia or Pistachio tree (*P. vera*) is a small tree of about 20 feet high, a native of Persia and Syria, but now cultivated in all parts of the south of Europe and north of Africa, and in many places naturalised. It has pinnate leaves, with about two pair of ovate leaflets, and an odd one, flowers in racemes, fruit ovate, and about the size of an olive. The stone or nut splits into two valves when ripe; the kernel, which is of a bright green colour, is very oleaginous, of a delicate flavour, and in its properties very much resembles the sweet almond. In the south of Europe and in the East *Pistachio nuts* are much esteemed; but as they very readily become rancid they are little exported to other countries. They are sometimes called *Green Almonds*. Oil is expressed from them for culinary and other uses. In cultivation one male tree is allowed to five or six fertile ones. The tree produces flowers and even fruit readily enough in the south of England, but the summers are not warm enough to ripen the fruit, and the tree is apt to be destroyed by a severe frost. The Mastic-tree, or Lentisk (*P. lentiscus*), yields the gum-resin called Mastic (q.v.). It is a native of the countries around the Mediterranean. The Turpentine-tree (*P. terebinthus*) yields the Turpentine (q.v.) known in commerce as *Cyprus Turpentine*, *Chian Turpentine*, or *Scio Turpentine*, which is of a consistency somewhat like that of honey, a greenish-yellow colour, an agreeable odour, and a mild taste, and in its properties resembles the turpentine of the Coniferæ, but is free from acridity. It is obtained by making incisions in the trees, and placing stones for the turpentine to flow upon, from which it is scraped in the morning, before it is liquefied again by the heat of the sun. The tree is about 30 or 35 feet in height, and has pinnate leaves, of about three pair of leaflets and an odd one, the flowers in compound racemes, the fruit nearly globular. The kernel of the fruit is oleaginous and pleasant. The Batoum Tree (*P. atlantica*), a round-headed tree about 40 feet in height, a native of the north of Africa, produces a fruit much used by the Arabs; and a gum-resin of pleasant aromatic smell and agreeable taste, which exudes from its stem and branches, is chewed to clean the teeth and impart a pleasant smell to the breath. The fragrant oil of the kernels of *P. oleosa*, a native of Cochin-China, is used there to perfume ointments.

Pistil, that part of the Flower (q.v.) which, after flowering is over, is developed into the fruit. See Fruit.

Pistoia (anc. *Pistoria*), a town of Italy, stands 21 miles by rail NW. of Florence, on a spur of the Apennines. Its streets are thoroughly Tuscan, and it is surrounded with walls, pierced by five gates, and has a citadel. The chief buildings are the cathedral of San Jacopo (12th and 13th centuries), containing a magnificent altar of silver (1286–1407) and several good pictures; the church of St Bartholomew, with a fine white marble pulpit by Guido of Como (1250); St Andrea, with Giovanni Pisano's pulpit (1301); St John, with a font by Giovanni Pisano and terra-cottas by Andrea della Robbia; the 14th-century communal palace; and other palaces. The principal manufactures are iron and steel wares, agricultural implements, paper, oil, and silk. But the town has the credit of having invented and first made pistols, and of having given them its name in the form *pistola*. Here Catiline was defeated in 62 B.C. The town was conquered by Florence and Lucca in 1306. Pop. 21,500.

Pistol is the smallest description of Firearms (q.v.). See also Revolver.

Pistole, a gold coin formerly current in Spain and Italy, and originally equivalent to about eleven old French livres, though till about 1730 it was merely an irregular piece of gold. Its value varied somewhat at different times and in different countries, usually being between fifteen and sixteen shillings. The gold pistoles once current in parts of Germany were in most cases merely convenient multiples of the ordinary thaler and gulden. The *louis d'or* was intended to take in France the same place as the pistole in Spain.

Pita-hemp, one of the names of the Agave fibre. See Fibrous Substances.

Pitaka, a division of the Buddhists' sacred literature; the *tripit'aka* meaning the three great divisions of their canonical works, the *Vinaya* (discipline), *Abhidharma* (metaphysics), and *Sútra* (aphorisms in prose), and collectively, therefore, the whole Buddhistic code.

Pit and Gallows, a rendering of the grant of capital jurisdiction (*cum fossa et furca*) made to vassals by the crown in feudal times. Male felons were usually hanged on the gallows (*furca*); women drowned in a ditch or well (*fossa*). See Baron, Drowning.

Pitaval, François Gayot de (1673–1743), compiler of the famous collection of *Causes Célèbres* (q.v.), served in the army, but became an advocate, and was known as an industrious and painstaking compiler. Of his great work there have been numerous abridgments, continuations, and translations; and his name has become so identified with the collecting of criminal cases that a similar work, published by various editors in Leipzig in 1843 and succeeding years, was called *Der Neue Pitaval* (2d ed. 36 vols. 1857–72; new series, 1866 *et seq.*).

Pitcairn, Robert (1793–1855), editor of the invaluable collection of *Criminal Trials in Scotland from 1484 to 1624* (4 vols. Edin. 1830–33), held a post in the Register House at Edinburgh. He was an active member of the Bannatyne Club, and secretary of the Calvin Translation Society (founded 1843).

Pitcairne, Archibald, physician and satirist, was born at Edinburgh, 25th December 1652. He studied first theology and then law at the univer-

sity of his native city; but having gone to France in ill-health, made final choice of medicine as his life study, completing a distinguished course at Paris. He practised with success in Edinburgh till 1692, when the fame of his treatise on Harvey's discovery of the circulation of the blood secured him a call to Leyden as professor. Here he remained only a year; his lectures being ultimately published as *Elementa Medicinæ Physico-Mathematica* (1718). He returned to Edinburgh to become one of the most famous physicians of his time; producing also *Dissertationes Medicæ* (1701). But he was even more notorious as a Jacobite, an Episcopalian, a satirist of Presbyterian men and things, and, according to his opponents, as an atheist and scoffer at religion. *The Assembly* is a comedy in ridicule of the General Assembly of the kirk; and *Babell, or the Assembly* (1692), is a poem with the same aim. His Latin verses, some of which were republished by Ruddiman in 1727, are creditable. He died 20th October 1713.

Pitcairn Island, a solitary island in the Pacific Ocean, between Australia and South America, in 25° 3′ S. lat. and 130° 8′ W. long., measures 2½ miles by 1 mile. It was discovered by Carteret in 1767, and was at that time uninhabited, although there were unmistakable evidences that it had been inhabited at one time. In 1790 it was taken possession of by nine of the mutineers of H.M.S. *Bounty* (see BLIGH), with six Tahitian men and a dozen women, the ringleader being called Christian. Four years later the native men one night murdered all the Englishmen, except Alexander Smith, who afterwards assumed the name of John Adams. Thereupon the women, in revenge, murdered all the Tahitian men. According to another account, the white men and the Tahitians murdered each other at intervals, until only two Englishmen were left alive. Certain it is that at the end of ten years John Adams was left alone, with eight or nine women and several children; and from them the present inhabitants (126 in 1890) are descended. Adams, changed by these tragic adventures, and sobered by his responsibilities, set about the education of his companions in Christian principles. The little colony was unknown to the world until 1808, when it was 'discovered' by Captain Folger of the American sealing ship *Topaz;* the first British vessel to visit it did not arrive until 1814. The islanders were visited again in 1825 and 1830, and in 1831, as their numbers had rapidly increased (to 87), they were at their own request removed to Tahiti by the British government. But, disgusted by the immorality and other undesirable customs of their Tahitian relatives, the most of them came back to Pitcairn Island after about nine months, in a vessel chartered by themselves. The island was annexed to Britain in 1839. Nearly 200 of the islanders were transferred to Norfolk Island in 1856, but a number of them afterwards returned. Pitcairn Island enjoys a lovely climate; its mountainous surface reaches 1008 feet in Outlook Ridge; the soil is fertile, and produces yams, cocoa-nuts, bread-fruit, sweet potatoes, bananas, &c. The people are degenerating, from intermarriage and their being able to live without exertion.

See Sir J. Barrow, *Mutiny of the Bounty* (1831); Lady Belcher, *Mutineers of the Bounty* (1870); T. B. Murray, *Pitcairn Island* (1854; new ed. 1885); Rosa Amelia Young [a native], *The Story of Pitcairn Island* (1895).

Pitch, the degree of acuteness of musical sounds. A musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals; the greater the number of vibrations in a given time the more acute or higher is the pitch (see SOUND). The pitch of musical instruments is adjusted by means of a tuning-fork, consisting of two prongs springing out of a handle, so adjusted as to length that when struck a particular note is produced, that note being C  in Britain, and A  in Germany. It is obviously important to have a recognised standard of pitch by which instruments and voices are to be regulated; but there is, unfortunately, not the uniformity that might be desired in the pitch in actual use. For two centuries, down to about 1827, the pitch in use was nearly uniform (C = 498 to 515 vibrations per second); but since then, owing mainly to an aim of wind-instrument makers to obtain greater brilliance of tone, it has constantly been rising, to the detriment of soprano voices especially, till in 1859, in the Covent Garden opera band, it was a semitone higher (C = 538). The French government, on the report of a special committee, in 1859 fixed the pitch of C at 522, which continues in use in France to this day, and is known as French pitch. An international conference, where all the chief European countries were represented except France and England, was held in Vienna in 1885, which resulted in the adoption of French pitch as the standard. In 1891 the American piano-manufacturers agreed to adopt French pitch. An effort towards uniformity of pitch in Great Britain, made in 1859–69 by the Society of Arts, and a subsequent attempt initiated by the Royal Academy of Music in 1885, had no practical result. Most British orchestras continue to play at the higher pitch (known as Philharmonic), while in music not orchestral, and with vocalists generally, a pitch about the French is used. The main obstacle to the lowering of pitch is the expense of new wind-instruments, it being impossible to lower the old ones to so great an extent. See A. J. Ellis, *History of Musical Pitch,* reprinted from the *Journal* of the Society of Arts, 1880, and given in abstract in *Nature,* vol. xxi.

Pitch. When the tar from wood or coal is distilled, volatile naphtha or 'spirit' is obtained at low temperatures, and as the heat is increased heavy oils and other products appear in the distillate. If the temperature reaches redness, coke or carbon is left as a residue, but if the fire is withdrawn before the distilling vessel becomes red—i.e. before the heavy oils in the tar begin to break up—the residue is pitch. A softer and tougher pitch is obtained if the fire is removed early than if the heat is continued till coking begins. In the latter case it is more black, glossy, and brittle. An elastic pitch is got from bone tar, and another from stearine residues, and both are valued by varnish and tarpaulin makers. Pitch is also obtained from natural petroleum. Wood-tar pitch is much more used in America than in England, chiefly for protecting timber from the weather and the attacks of insects. Coal-tar pitch is most largely employed in the manufacture of patent fuel, from 5 to 8 per cent. of it being required to form Briquettes (q.v.) of small coal or coke breeze. It has other applications, such as in the manufacture of black varnishes for coating iron, and to a less extent for protecting wood and other substances, in the preparation of artificial asphalt (see ASPHALT), and to yield lamp-black when burned. *Burgundy Pitch* is the subject of a separate article (see also PINE). In some parts of Persia and Afghanistan a kind of pitch is prepared by the destructive distillation of goat and sheep dung, which is applied as a remedy for sores or ulcers on sheep and some other animals.

Pitcher-plant. See INSECTIVOROUS PLANTS.

Pitch Lake. See TRINIDAD.

Pitchstone, or RETINITÉ, an acid volcanic glass, dark green, reddish brown, yellow, dark blue, or black, and occasionally showing a streaked or clouded appearance. It has a pitch-like or greasy lustre, breaks with a conchoidal or splintery fracture, and is translucent on thin edges. It is usually rich in microlites, and often contains crystalline granules and crystals of felspar, pyroxene, hornblende, biotite, and quartz. Now and again it shows perlitic and spherulitic structures. When conspicuous crystals of sanidine (see FELSPAR) are abundantly present in the rock it is termed *Pitchstone Porphyry*. It occurs in the form of dykes and also as lava-flows. The name pitchstone has sometimes been given to the darker varieties of menilite, a form of opal.

Pith, or MEDULLA, is the central cylinder of tissue in the stems of Dicotyledons and Gymnosperms. In all plants where it is found it is continuous in the young state. In older plants it may be continuous, as in the elder, oak, &c., in the form of transverse discs, as in the walnut, or wanting in the internodes, as in hemlock, &c. In very young plants it is composed of thin-walled cells filled with protoplasm and cell-sap, and takes part in the conduction of nutritive substances throughout the plant. The cell-walls usually remain very thin, the protoplasm is soon all used up within the cells, and their further growth ceases. Examined microscopically, pith cells are usually polygonal in transverse section, while they are rectangular in longitudinal section, and not much longer than broad. The ring of wood immediately surrounding the pith consists largely of spiral and annular vessels, and is known as the medullary sheath. The pith is connected with the cortex and bast by the medullary rays, which are composed of cells similar to those of the pith, and which convey sap to the inner parts of the stem. In the early life of most trees the pith serves as a storehouse for starch and other reserve substances; but as the tree becomes older the pith is crushed inwards, communication with the cortex and bast is physiologically obstructed, and the pith cells become dry and full of air.

Pithecanthropus erectus ('erect apeman'), the name given by Dr Eugene Dubois, of the Dutch army medical service, to the animal reconstructed from fossilised remains found by him in Java. These consist of the upper part of a cranium, a left femur, and two molar teeth, and were found in 1891–2 on the left bank of the Bengawan river, near Trinil, during explorations conducted for the government of the Dutch Indies. The cranium and teeth were found close together, and the femur a few yards away and a year afterwards; but Dr Dubois believes them to belong to the same skeleton, and to be such as could only have belonged to an animal midway between man and the higher apes, and of pleistocene age. The cranium is midway in form and size between the normal human and the gorilla's skull, and rather closely resembles that of a microcephalous idiot. The find has given rise to much discussion and difference of opinion; many authorities holding that the femur and cranium have not been proved to belong to the same skeleton, and that, while the femur is undoubtedly human, the cranium is also probably of a very low human type; others wholly or partly agree with Dr Dubois. The diversity of opinion extends to the teeth, which are large and powerful.

See the discoverer's monograph, *Pithecanthropus erectus* (Batavia, 1894, in German); the paper read by Dr Dubois to the Royal Dublin Society, Jan. 23, 1895; *Nature*, vols. li., lii., liii., liv.; and in the present work the articles ANTHROPOID APES, MAN, SKULL.

Pithe'cus (Gr., 'ape'), a name formerly used by zoologists for various groups of apes and monkeys. See SAKI.

Pithom, one of the store-cities which the children of Israel built for Pharaoh (Exod. i. 11), conclusively identified in 1883 by the excavations of M. Naville with the deserted Arab village Tell El-Maskhûta, on the Fresh-water Canal and railway line from Cairo to Ismailia, about half-way between Ismailia and Tell El-Kebîr. See Naville's *Store City of Pithom* (1885).

Pitlochry, a Perthshire health-resort, on the Tummel, 13 miles NNW. of Dunkeld. It has a tweed manufactory. Pop. 1131.

Pitman, SIR ISAAC, founder of the Pitman system of Shorthand (q.v.), who was knighted in 1894, was born at Trowbridge, Wiltshire, 4th January 1813. His father, a factory overseer and afterwards cloth manufacturer, was superintendent of the poet Crabbe's Sunday-school. Young Pitman, a studious and religiously disposed youth, was for a time a clerk, and after some preliminary training taught a school at Barton-on-Humber (1832–36) and at Wotton-under-Edge, where he turned his attention to the popularising of shorthand, and issued through Bagster his *Stenographic Sound Hand* (1837). Copies of his second edition were put into circulation simultaneously with the introduction of the penny post in 1840. Dismissed from Wotton because he had joined the New (Swedenborgian) Church, he conducted a school at Bath (1839–43). Henceforward his career is the history of the development of shorthand and spelling reform. He wrote, travelled, and lectured in its interest, his working day commonly lasting from 6 A.M. till 10 P.M., with three hours for meals and relaxation. In 1842 he brought out the *Phonetic Journal*, with which the late A. J. Ellis was for a time associated. In 1845 premises were opened in London for the sale of Pitman's publications. In recognition of his exertions he was presented with £350 and a marble timepiece in 1862, and at a phonographic jubilee meeting in 1887 was presented with a marble bust of himself. He died 22d January 1897. In his early days he spent much of his narrow income in the cause. Up till 1890 he had issued from his Phonetic Institute, Bath, 150 different shorthand books, and his *Phonographic Teacher* was selling at the rate of 150,000 annually. From the date of issue 1,370,000 had been sold. There were also eighty-four shorthand associations, and a National Phonographic Society, whilst the subject had been recognised in the Education Code (1890) and the Technical Instruction Act of 1889, so that Pitman's labours of more than half a century have been crowned with success. About 95 per cent. of reporters in England, the colonies, and America use Pitman's system, which has been adapted to the Welsh, French, German, Italian, Spanish, Dutch, Japanese, and Malagasy languages. It is estimated that its practitioners all over the world number above half a million. See T. A. Reed's *Biography of Isaac Pitman* (1890).

Piton Bark. See CARIBBEE BARK.

Pitra, JEAN BAPTISTE, was born at Champforgueil, near Autun, August 31, 1812, entered the order of St Benedict, and devoted himself to historical studies in the abbey of Solesme. In 1858 he was sent by the pope to Russia to study the Slavonic liturgy, was created a cardinal-priest in March 1863, librarian of the Vatican in 1869, and Cardinal-bishop of Frascati in 1879. He died February 3, 1889. His works include *Histoire de Saint Leger* (1846), *Vie du R. P. Libermann* (1855), the invaluable *Spicilegium Solesmense* (5 vols. 1852–60), *Juris Ecclesiastici Græcorum*

Monumenta (1864), *Triodion Katanacticon* (1879), and *Hymnographie de l'Église Grecque* (1867).

Pitrè, GIUSEPPE, the greatest of Italian folk-lorists, was born at Palermo, 23d December 1841. His father dying during his childhood, he was brought up by the self sacrificing care of a devoted mother, and on the outbreak of the revolution in 1860 volunteered into the army of Garibaldi. At the close of the war he studied medicine at Palermo, graduating in 1866. While yet a student he had begun his literary career with *Sui Proverbi Siciliani e Toscani* (1862), *Profili biografici di contemporanei Italiani* (1864), &c.; but about 1868 he began the great work of his life when he left the study of literature proper for that of popular literature and folklore generally. With incessant and enthusiastic labour he has since devoted himself to his chosen study, and enriched science and honoured his native land with a long series of books and papers of the highest value. His 'Biblioteca delle Tradizioni popolari Siciliane' alone includes 19 volumes (1870–91), the most important of which are the *Canti popolari Siciliani* (2 vols. 1870–71; 2d ed. 1891); *Fiabe, Novelle e Racconti popolari Siciliani* (4 vols. 1875); *Proverbi Siciliani* (4 vols. 1880); and *Usi e Costumi, Credenze e Pregiudizi del popolo Siciliano* (4 vols. 1887–89). Still another series, the 'Curiosità popolari Tradizionali,' includes ten volumes (1885–91). Much of Dr Pitrè's best work has been contributed to the pages of the well-known folklore quarterly, the *Archivio per lo Studio delle Tradizioni popolari*, edited from its foundation in 1882 by himself and S. Salomone-Marino. Besides the foregoing Dr Pitrè has published an exhaustive *Bibliografia delle Tradizioni popolari d'Italia* (1891); many monographs and papers on Sicilian folk-songs; proverbs; riddles; historical traditions; customs connected with birth, marriage, death, and burial; as well as special popular beliefs and superstitions, as those connected with particular festivals, Friday, the Evil Eye, and the like. Good collections are his *Novelline popolari Toscane* (1878), and *Novelle popolari Toscane illustrate* (1884).

Pitri (Sansk., 'father;' plur. *Pitaras*), the deceased ancestors of a man, but in the special sense in which the word occurs in Hindu mythology, an order of divine beings inhabiting celestial regions of their own, and receiving into their society the spirits of those mortals for whom the funeral rites have been duly performed. They include therefore collectively the manes of deceased ancestors (see LARES); but the principal members of this order are beings of a superior nature.

Pitscottie, ROBERT LINDSAY OF, the author of *The Chronicles of Scotland*, extending from the reign of James II. to the year 1565. There is nothing to learn of Lindsay personally, except that he was born about the beginning of the 16th century, and was proprietor of the lands of Pitscottie in Fifeshire. He is best known by his territorial appellation. His Chronicle was Sir Walter Scott's favourite Scottish history; and though Pitscottie was not contemporary with the whole of the events he describes, he must, for the latter portion of his history, have derived much of his information from eye-witnesses. His style is quaint and graphic, and his facts in general trustworthy, except where he deals in marvels, to which he is a little prone. It is he, for instance, who tells, on the authority of Sir David Lyndsay, Lyon King-of-arms, that striking story of the intrusion of the apparition to the presence of James IV. in Linlithgow, of which Scott gives a vivid picture in *Marmion*. The best edition of Pitscottie's history is Dalyell's (2 vols. 1814).

Pitt, WILLIAM, the second son of the great Earl of Chatham and of Lady Hester Grenville, was born at Hayes, near Bromley, in Kent, on 28th May 1759. At the time of his birth his father was still in the House of Commons and in the very zenith of his fame, and the future statesman grew up amid associations and surroundings that were well fitted to foster that political ambition which was to be the guiding and almost the sole impulse of his life. His constitution in boyhood seemed very weak; he was never sent to school, but his education advanced so rapidly under a private tutor, that he was able to enter Cambridge when only fourteen. He was then a shy, reserved boy of exceedingly precocious talents, of irreproachable morals, and of regular and studious habits, little drawn to college society and amusements, and already distinguished by a rare self-control and concentration of purpose. From his earliest youth political life was placed before him as his ideal, and all his studies converged to that end. He became an excellent classical scholar, but he valued the classical writers mainly as a school of language and of taste; and it was observed how carefully he analysed their styles, noted down every just or forcible expression, and compared the opposite speeches on the same subject, observing how each speaker met or evaded the arguments of his opponent. Like many others he found in Locke a great master of clear and accurate thinking. His father superintended his studies with much care, and it was remembered that he specially recommended to him the sermons of Barrow as models of style and reasoning, and the histories of Polybius and Thucydides as fountains of political wisdom; that he taught him elocution by making him declaim the grandest poetry in Shakespeare and the speeches of the fallen angels in the *Paradise Lost;* and that he exercised him in fluency by accustoming him to translate into flowing English long passages from the classical writers. To this last practice Pitt largely ascribed that amazing command of choice and accurate English in which he surpassed all his contemporaries. When little more than a boy he was an attentive and discriminating listener to the debates in parliament. He became thoroughly familiar with the matchless eloquence of his father, and together with his brother-in-law, Lord Mahon, he supported his father into the House of Lords on the 7th April 1778 on that memorable occasion when Chatham delivered his last speech against the surrender of America, and fell down, stricken by mortal illness, on the floor of the House.

Copyright 1891 in U.S. by J. B. Lippincott Company.

Pitt was left with a patrimony of less than £300 a year. He was called to the bar in the June of 1780, and went on the Western Circuit, but in September parliament was dissolved, and he at once threw himself into politics. He stood for Cambridge University, but found himself at the bottom of the poll; his disappointment, however, was speedily allayed, for Sir James Lowther gave him a seat for his pocket-borough of Appleby, and Pitt entered the House of Commons on 23d January 1781.

He came into the House bearing a name which was beyond all others revered by Englishmen, with the advantage of being in no way mixed up with the calamitous American war, and with talents that had already acquired an extraordinary maturity. The Tory ministry of Lord North was then tottering to its fall, crushed by the disasters in America, and confronted by an opposition which consisted of the Old Whigs who followed Rockingham, among whom Fox and Burke were conspicuous, and of a smaller body who had been especially attached to the fortunes of Chatham, and who were chiefly represented by Shelburne. Camden, and Barré. Pitt lost no time in throwing himself

into the fray. He spoke on the 26th February with brilliant success in defence of Burke's Bill for Economical Reform, and on several successive occasions he assailed the falling ministry. He denounced the American war and the corrupt influence of the crown with extreme violence, but he refused to throw in his lot irrevocably with the party of the opposition, and shortly before the fall of North he publicly declared that he could not expect to bear a part in the coming ministry as he 'would never accept a subordinate position.' The words are said to have escaped from him in the heat of the debate, and the House was startled and a little amused at the arrogance of a young man who was not twenty-three, who was absolutely without official experience, and who had been little more than a year in parliament, declaring that he would accept no office except in the Cabinet.

But Pitt had attained a position that placed him far above lasting ridicule. Fox spoke of him as already one of the first men in parliament. Burke said of him that he was not a chip of the old block, but the old block itself; Horace Walpole wrote that he had shown logical powers that made men doubt whether he might not prove superior even to Fox; and when upon the resignation of North in March 1782 a ministry was formed under the leadership of Rockingham, combining the two sections of the opposition, Pitt remembered his pledge and refused several offers, among others the Vice-treasurership of Ireland with a salary of £5000 a year. He gave, however, a general and cordial support to the new ministers, but he at the same time brought forward the question of parliamentary reform, on which they were profoundly divided. It was a question which fell naturally to him, for his father had been one of the first to urge it. On the 7th May he moved, in a speech of great brilliancy, for a select committee to inquire into the state of the representation, and was only defeated by 161 to 141. He soon afterwards supported a measure of Sawbridge for shortening the duration of parliament, and a measure of Lord Mahon for preventing bribery at elections.

A close personal and political connection about this time grew up between Pitt and Henry Dundas, who had been Lord Advocate under North. It proved of great importance to the career of Pitt. Dundas had none of the intellectual brilliancy or of the moral dignity of the younger statesman, but he had one of the best political judgments of his time, he had great talents both for business and for debate, and he was a most shrewd and sagacious judge of the characters of men—a gift in which Pitt through his whole life was somewhat wanting.

The Rockingham ministry lasted only for three months. The king detested it; it was from the first profoundly divided, and a bitter personal and political animosity had broken out between Charles Fox and Lord Shelburne, its two most conspicuous members. On 1st July 1782 Lord Rockingham died, and the question of leadership at once broke up the party. Fox insisted on the leadership of the Duke of Portland, a wealthy and respectable, but perfectly undistinguished nobleman, who was then Lord-lieutenant of Ireland. The king gave the post of First Lord of the Treasury to Shelburne, who had an incomparably higher political position, and who had been a favourite friend and colleague of Chatham, though there were features in his character that already excited great unpopularity and distrust. Fox, with a considerable section of the Rockingham Whigs, at once resigned, and Pitt entered the Cabinet as Chancellor of the Exchequer in the reconstructed ministry. Public opinion generally blamed Fox, and one of the consequences of his resignation was that the House of Commons was divided into three distinct parties. There was the party of Fox, the party of North, and the party of the government, and no one of them could command a clear majority. A coalition of some kind was inevitable. Shelburne leaned towards an alliance with North, but Pitt positively refused to have any connection with the statesman whom he deemed responsible for the American war. Peace was not yet attained, but the negotiations which had been pursued by the preceding ministry were steadily pushed on. Provisional articles of peace between England and the United States were signed in November 1782, and preliminary articles with France and Spain in the following January, while a truce was established with Holland, and the first steps were taken towards a very liberal commercial treaty with the United States.

Pitt bore a leading part in the debates in parliament, and his reputation steadily rose, but the Shelburne ministry was weak, divided, and short-lived. The peace following a disastrous war necessarily involved sacrifices that were profoundly unpopular, and the character of Shelburne aggravated the divisions that had already appeared. Several resignations took place, but Pitt stood loyally by his chief, and endeavoured without success to induce Fox to rejoin the ministry. Fox, however, declared that he would never again serve any ministry with Shelburne for its head, and to the astonishment and indignation both of the king and of the country, he united with the very statesman whose expulsion from public power had been for years the main object of his policy, and whom he had repeatedly threatened with impeachment. North, irritated at the ostracism with which he had been threatened, readily entered into the alliance. Two factious votes of censure directed against the peace were carried through the Commons by majorities of 16 and 17, and on 24th February 1783 Shelburne resigned.

Pitt had displayed the most splendid parliamentary talents in the discussions that preceded the fall of the ministry, and although he could not overthrow the compact weight of parliamentary influence opposed to him, he profoundly moved the country and placed his own position beyond dispute. On the fall of the Shelburne ministry, the king, hoping to escape the yoke of the coalition, implored the young statesman to accept the leadership, and gave him an absolute authority to name his colleagues. It was a dazzling offer, and Pitt was not yet twenty-four, but he already possessed a judgment and a self-restraint which is rarely found at any age in combination with such brilliancy and such courage, and he saw clearly that the moment of triumph had not yet come. After a long struggle and many abortive efforts the king was obliged to yield, and on the 2d April the coalition ministry was formed with the Duke of Portland as First Lord of the Treasury, and Fox and North as joint Secretaries of State.

It commanded a large majority of the votes, and included a great preponderance of the ability in the House of Commons, but the king viewed it with a detestation amounting to loathing, and the nation was profoundly scandalised by the alliance on which it rested. Pitt was offered his old post of Chancellor of the Exchequer, which he peremptorily refused. As leader of the opposition, he brought forward, in the form of resolutions, an elaborate scheme of parliamentary reform, including an increase of the county members. He was defeated by 293 to 149, but he at least succeeded in bringing Fox and North into direct collision. He brought forward another important measure for the reform of abuses in the public offices, which passed the Commons but was rejected in the Lords. The peace which was carried by the new ministry differed very little from that which they had

censured when in opposition ; and very soon the bill of the government for subverting in some important respects the charter of the East India Company and reorganising the government of India, produced another great change in the disposition of power.

The feature of the scheme which chiefly excited indignation and alarm was the creation by the existing legislature of a new supreme body in England, consisting of seven commissioners who were to be immovable except by an address from either house for four years, and who were during that period to have an absolute control of the patronage of India. It was contended that this measure would give the party who were now in power an amount of patronage which would enable them to overbalance the influence of the crown, dominate the parliament, and control succeeding administrations. These objections were brought forward by Pitt with great power, but with extreme exaggeration, and the king and the nation were speedily alarmed. The India Bill passed by large majorities through the Commons, but when it came into the House of Lords the king authorised Lord Temple to say that he would consider any man his enemy who voted for the bill. The communication produced an immediate effect. The bill was rejected in the Lords by 95 to 76; the ministry refused to resign, and the House of Commons supported them by large majorities ; but the king peremptorily dismissed them on 18th December 1783, and next day it was announced that Pitt had been called to the head of affairs as Chancellor of the Exchequer and First Lord of the Treasury.

Pitt had already abundantly displayed his parliamentary ability, his judgment, and his discretion. He was now to display in the highest degree his courage. In the eyes of nearly all the best judges in England his position was a hopeless one, and his administration was likely to be even more brief than the three which had preceded it. There was a majority of more than a hundred against him in the Commons, and the parliamentary influence behind it was so great that an immediate dissolution must have been disastrous. He was called to office by a grossly unconstitutional interference on the part of the king, and every day which he remained in office under the censure of the House of Commons added to the falseness of his position. Temple, on whom he had greatly relied, threw up the seals of Secretary of State which he had accepted, and in the House of Commons Pitt was himself at this time the only cabinet minister, while Dundas was the only considerable debater who supported him against the united attacks of North, Fox, Burke, and Sheridan. But Pitt fought his battle with a skill and a resolution that have never been surpassed in parliamentary history. A long succession of hostile votes was carried, but they failed to drive him from office, and soon unequivocal signs appeared that the country was with him. The magnanimity with which at this critical period he refused to take for himself a great sinecure office which fell vacant added greatly to his popularity. Addresses in his favour poured in from all the leading corporations in the country. The majorities against him grew steadily smaller. At last, on 25th March 1784, the long-deferred blow was struck. Parliament was dissolved, and an election ensued which swept away nearly 160 members of the opposition, made Pitt one of the most powerful ministers in all English history, and prepared the way for a ministry which lasted, with a few months' intermission, for no less than twenty years.

In this great and powerful ministry English political life assumed much of its modern aspect. The House of Commons acquired a new importance in the constitution, the people a new control over its proceedings, and the First Lord of the Treasury complete ascendency in the government. The system of 'king's friends' controlling the ministry was finally destroyed, and when the chancellor, Lord Thurlow, attempted to perpetuate it, he was peremptorily dismissed. The skilful management of the regency question established the right of parliament to provide for the exercise of supreme power during the incapacity of the king. Direct parliamentary corruption was finally put down. Great numbers of sinecure places were abolished, and great reforms were introduced into the system of collecting the revenue and issuing public loans. The government of India was reorganised on the system of a double government, which continued with little change till the abolition of the East India Company in 1858. The whole system of taxation and of trade duties was thoroughly revised, and no minister since Walpole had approached Pitt in his complete competence in dealing with trade questions. The finances of the country, which had been extremely disorganised by the American war, became once more flourishing. A commercial treaty, based upon more enlightened commercial doctrines than any English statesman, except Shelburne, had yet adopted, was negotiated with France. In foreign politics Pitt was for some years equally successful. Some troubles that had arisen with Spain were put down by a display of prompt and judicious firmness. In conjunction with Prussia a revolutionary movement in Holland which was fomented by French influence was suppressed, and the triple alliance of England, Prussia, and Holland contributed largely to terminate the wars between Sweden and Denmark and between the emperor and the Turks, though it met with a mortifying failure in its dealings with Russia. Pitt's love of peace was very sincere, but the influence of England in European councils rose greatly under his ministry, and he showed much decision and tact in extricating England from a dangerous complicity with the ambitions designs of her Prussian ally. Up to the time of the French Revolution there was no decline in his ascendency, his popularity, or his success.

A few adverse criticisms, however, may be justly made. He cast aside too lightly on the first serious opposition parliamentary reform and the abolition of the slave-trade, and it became evident to good observers that he cared more for power than for measures, and was ready to sacrifice great causes with which he had sincerely sympathised and which he might have carried, rather than raise an opposition that might imperil his ascendency. His once famous Sinking Fund is now universally recognised to have been thoroughly vicious in its principle ; and in the latter part of his career it led him to the absurdity of borrowing largely at high interest in order to pay off a debt that had been contracted at low interest. His attempt to establish free trade between England and Ireland failed through an explosion of manufacturing jealousy in England, which obliged him to modify his original propositions in a way which was unpalatable to the Irish. More real blame attaches to him for his opposition to all serious measures to remedy the enormous abuses in the Irish parliament and for the great uncertainty of his policy towards the Irish Catholics. The great evils which grew up in England in his time in connection with the sudden development of the factory system appear never to have attracted his attention, and he made no effort to mitigate them. He created peerages with extreme lavishness and with very little regard to merit, and although his patronage was not positively corrupt, few ministers have

shown themselves more indifferent to the higher interests of literature, science, and art.

When the French Revolution broke out his policy was one of absolute neutrality towards the contending parties, and this neutrality he most faithfully observed. He wholly failed, however, to understand the character and the supreme importance of the Revolution. He believed that it was merely a passing disturbance, and that its principal effect would be to deprive France for some years of all serious influence in European affairs, and almost to the eve of the great war he was reducing the armaments of England. There is no real doubt that he was forced most reluctantly into war by the aggressive policy of France in Flanders and towards Holland; but he drew the sword believing that France was so disorganised and bankrupt that a struggle with her would be both short and easy; he was almost wholly destitute of the kind of talents that are needed for a war-minister, and he had to contend with an almost unexampled outburst of military enthusiasm, and soon after with the transcendent genius of Napoleon. His belief in the probable shortness of the war and in the efficacy of his sinking fund, led him into the great error of raising his war expenses in the first stages of the war almost wholly by loans, and thus laying the foundation of an enormous increase of debt. His military enterprises were badly planned and badly executed, and he had none of his father's skill in discovering and bringing forward military talent. For some years it is true his ascendency in parliament continued to increase. The great Whig schism of 1794 and the secession of Fox reduced the opposition to utter insignificance. But even in his domestic measures Pitt was no longer fortunate. Through fear of the revolutionary spirit which had infected some portions of the population, he was led into repressive measures very little in harmony with his earlier career. Corn had risen to famine price, and great distress prevailed, and the government attempted to meet it by very ill-conceived relaxations of the poor-laws—by levying rates for the purpose of increasing wages, and by granting parochial relief in proportion to the number of children in a family, and thus offering a direct premium to improvident marriages. In Ireland disaffection was steadily growing, and Pitt tried to win the Catholics by measures of conciliation, and especially by the concession of the suffrage; but the opposition of the king, divided councils, and the vacillation of his own mind impaired his policy, and the injudicious recall at a very critical moment of a popular viceroy contributed largely to the savage rebellion of 1798. He then tried to place Irish affairs on a sound basis by a legislative union which was to be followed by Catholic emancipation, the payment of the priests, and a commutation of tithes. The first measure was carried by very corrupt means, but the king, who had not been informed of the ultimate intentions of his minister, declared himself inexorably opposed to Catholic emancipation, which he deemed inconsistent with his coronation oath. Pitt resigned his office into the hands of his follower Addington in February 1801; but a month later, on hearing that the agitation of the Catholic question had for a time overthrown the tottering intellect of the king, he declared that he would abandon the Catholic question during the remainder of the reign, and he resumed office in May 1804 on the understanding that he would not suffer it to be carried. His last ministry was a melancholy and a humiliating one. The war, which had been suspended by the peace of Amiens, had broken out with renewed vehemence. There was great danger of invasion, and Pitt earnestly desired to combine the most eminent men of all parties in the ministry; but the king forbade the admission of Fox. The principal followers of Fox refused to join without their chief, and Lord Grenville and his followers took the same course. Grenville, who had long been one of Pitt's ablest colleagues, was now completely alienated. A junction with Addington was effected, but it lasted only for a short time, and it added little to the strength of the ministry. Dundas, Pitt's oldest friend and colleague, had been lately made Viscount Melville. He was placed at the head of the Admiralty; but a charge of misappropriating public funds was raised against him, and in 1805 he was driven ignominiously from office. Pitt's own health was now broken. His spirits had sunk; the spell which had once surrounded him had in a great degree passed away, and although the victory of Trafalgar saved England from all immediate danger of invasion, the disasters of Ulm and Austerlitz threw a dark cloud over his closing scene. He died in his forty-seventh year on 23d January 1806. The House of Commons by a great majority voted him a public funeral and a monument in Westminster Abbey.

He was never married, and he never mixed much in general society; but in all his private relations he was pure, amiable, simple, and attractive. He was a warm friend. His temper was very equable, and till near the close of his life very cheerful. He had much ready wit, and he could easily throw off the cares of office, and even join heartily in the games of boys. He maintained to the last his familiarity with the classics, but his serious interests were exclusively political. He only once crossed the Channel, and he appears to have been wholly untouched by the great contemporary currents of literature and non-political thought. He was not free from the prevailing vice of hard drinking, and he has been justly blamed for having allowed his great indifference to money to degenerate into a culpable carelessness. In 1801 some of his friends subscribed £12,000 towards the payment of his debts, and in the following year he sold Holwood, his country place. But these measures proved wholly insufficient. With no extravagant tastes, with no family to support, with no expensive elections, and with an official income of at least £10,000 a year, he left £40,000 of debt, which was paid by the nation. In public he was cold and repellent, and there was something theatrical in the unvaried dignity of his demeanour; but few men possessed to a higher degree the power of commanding, directing, and controlling, and he inspired the nation with an unbounded confidence both in his character and in his abilities. England has seen no greater parliamentary leader, few greater masters of financial and commercial legislation, and he was one of the first statesmen to adopt the teaching of Adam Smith. If his eloquence was very diffuse, if it showed little imagination, or depth or originality of thought, it was at least supremely adapted to all the purposes of debate, and it rarely failed in its effect. He was, in a word, a great peace-minister; but in the latter part of his life an evil fate brought him face to face with problems which he never wholly understood and with difficulties which he was very little fitted to encounter.

His political life has been written in much detail by Tomline and by Gifford; but by far the fullest and best biography of him which has yet appeared is that of Lord Stanhope. Lord Macaulay has made him the subject of a well-known biographical essay, and Mr Goldwin Smith of two brilliant lectures, and the reader may consult the monographs by Mr Walford (1890) and Lord Rosebery (1891). The career of Pitt, however, is indissolubly intertwined with the whole English history of his time, and in that connection it may best be studied.

Pittacus, one of the 'Seven Wise Men' (q.v.) of ancient Greece.

Pittenweem, a small seaport of Fife, a royal (since 1542) and parliamentary burgh (St Andrews group), 3½ miles NE. of Elie by rail, with fisheries. There are ruins of a 12th-century priory. Pop. (1891) 1962.

Pittsburgh, the second city of Pennsylvania, is built on a narrow strip of land where the Allegheny and Monongahela rivers meet to form the Ohio: it extends some 7 or 8 miles up the rivers, and 2 or 3 miles down the Ohio. Pittsburgh is by rail 444 miles from New York, 354 from Philadelphia, and 468 from Chicago. The business portion of the city is on a plain, less than a mile in width, along the banks, while the hills, commanding delightful views, are covered with handsome residences. In this region, where the prevailing soft shales and sandstones have been worn away by the rivers to a depth of 500 or 600 feet, the horizontal layers of coal are exposed, and access afforded to the coal-seams on the sides of the hills and at the bottom of the valleys to an extent elsewhere unknown; the great Pittsburgh coal layer, 8 feet thick, like a broad black band extends around the city 300 feet above the river. Since the introduction of natural gas (see below) the former sobriquet of the 'smoky city' is a misnomer; the clearness of the atmosphere has given an impetus to architecture, and the many new dwellings and business houses are really models of beauty and solidity. The court-house, costing $2,500,000, is of Quincy granite, and is connected with the gaol by a 'bridge of sighs.' The government building cost $1,500,000, and there are besides a city hall of white sandstone, a new Exposition Building, and numerous churches, among which the large Roman Catholic cathedral and Trinity Church (Episcopal) deserve notice. Pittsburgh possesses a good system of schools, and is the seat of a Catholic college. The Carnegie free library was dedicated in 1890. The three rivers are crossed by fifteen bridges, some of them monuments of engineering skill; and the different parts of the city are also connected by a dozen lines of cable, electric, and horse cars.

Copyright 1891 in U.S. by J. B. Lippincott Company.

Pittsburgh's manufactures include everything which can be made of iron, from a 58-ton gun to nails and tacks; steel in its various applications; all descriptions of glass and glassware; silver and nickel-plated ware; Japan and Britannia ware; pressed tin, brass, bronzes; earthenware, crucibles, fire-pots, bricks; furniture, wagons and carriages; brushes, bellows, mechanical supplies of all kinds; natural-gas fittings, tools for oil and gas wells, &c. The production of iron and steel in Pittsburgh and the vicinity is about one-fifth of the total production in the United States. The city contains over twenty blast-furnaces, which in 1890–95 produced about 1,500,000 tons of pig-iron annually (about one-seventh of the amount of the whole country), and over thirty rolling-mills, almost all of which roll steel; their annual production is well over 1,000,000 tons of steel and some 700,000 tons of rolled iron. Of wrought-iron pipe 350,000 tons, and of iron and steel for structural purposes 65,000 tons, are manufactured yearly. There are fifty iron-foundries, representing a capital of $10,000,000, two mills for rolling copper, and a dozen manufactories of white lead, lead paint, lead pipe, or shot. Of glass-factories there are thirty-four where window-glass is made, thirty-seven for flint and lime glass, ten for lamp-chimneys, five for green bottle-glass, and fifteen for prescription-vials.

Eight separate companies—with one directing head—for manufacturing air-brakes, automatic signals, electric light apparatus, and supplying heat and light have a combined capital of $23,170,000. The incandescent lamp has been brought to the greatest state of perfection in this city. Since about 1883 natural gas has been largely used for domestic and manufacturing purposes (see GAS-LIGHTING, Vol. V. p. 105). It is obtained from isolated districts a few miles in extent, within a radius of 20 miles from the city. By drilling into the earth from twelve to fifteen hundred feet a natural gas—mainly methane—rushed from the opening with a pressure of four or five hundred pounds to the square inch, which was found sufficient to force it through pipes to the houses and factories in the city. The purity of this gas, its great heating power, and its cleanliness make it a most excellent substitute for coal for domestic and manufacturing purposes. In 1890 some 7,500,000 cubic feet of this gas were daily consumed in the city. But of late the supply is less abundant, and some factories have returned to the use of coal. In 1892 there were terrible strikes, accompanied by much fighting and bloodshed, at the Carnegie steel-works at Homestead, near Pittsburgh.

The position of Pittsburgh on the eastern border of the great Mississippi river-basin, and her facilities for penetrating to every part by river and rail, give her great natural advantages for trade, and as a depôt for exchange and trans-shipment of the produce that naturally comes to her as a centre. In the river business over $9,500,000 are invested. Two lines of packets ply on the Monongahela and three on the Ohio. Seventy tow-boats and thousands of coal-boats, barges, and flats are engaged in the coal trade. In 1889 4,000,000 tons of coal were sent by river to the southern states, while 16,000,000 tons more—making altogether about two-thirds of the yearly output of bituminous coal for the entire state—were sent away by rail or consumed in Pittsburgh itself. In the district there are 15,000 coke-ovens making 6,000,000 tons of coke. Twelve district railroads centre here, six of which are trunk lines. These lines reach out to all points of the compass. The immense volume of transcontinental business passing through Pittsburgh annually is probably excelled by no city except perhaps Chicago. Pittsburgh has twenty-seven national banks and twenty state banks, with a total capital of $14,856,750. The interests of Allegheny City (q.v.; pop. in 1890, 105,287), on the opposite bank of the Allegheny River, though it is a separate municipality, are in all respects identical with those of Pittsburgh.

History.—In the early history of America the site of Pittsburgh was a point of great interest, and was familiarly known as the 'Gateway to the West.' Here traders, settlers, and adventurers, who had worked their way from Philadelphia by a chain of forts, congregated, and here flat-boats were built which carried them down the Ohio to the unknown regions beyond. In 1754 a few English traders built a stockade at the point, but were driven away by the French the following April. The latter replaced the stockade by a fort, which, in honour of the governor of Canada, they called Duquesne. It was near the present outskirts of the city that Braddock (q.v.) was surprised in 1755; and on October 15, 1758, General Grant and his Highlanders had reached the hill on which the court-house now stands when they were surrounded by the Indians and nearly exterminated. The following month, however, General Forbes took possession of what remained of old Fort Duquesne, the French having fled down the Ohio, leaving the buildings in ruins. In 1759 the English commenced a large and strong fortification, which, in honour of the elder Pitt (see CHATHAM, EARL OF), then prime-minister, they called Fort Pitt. The fort is

said to have cost the English government £60,000. The settlement became a borough in 1804, and in 1816 the borough was incorporated as the city of Pittsburgh. Pop. (1810) 4768; (1840) 21,115; (1870) 86,076 (with Birmingham, included soon after, 121,799); (1880) 156,389; (1890) 238,617.

Pittsfield, capital of Berkshire county, Massachusetts, 151 miles by rail W. of Boston. Beautifully situated on a plateau where six lakes round the city give rise to the Housatonic River, it contains a marble court-house, a handsome athenæum, and a ladies' seminary, and has a fine park near its western border. Cotton and woollen goods, silk, boots and shoes, and tacks are manufactured. Pop. (1860) 8045; (1880) 13,364; (1890) 17,281.

Pittston, a mining-town of Pennsylvania, on the Susquehanna River, 9 miles by rail NE. of Wilkesbarre. Besides a railway bridge, there are two other bridges connecting it with West Pittston (4000). Pittston contains also a number of foundries and knitting-mills, and a silk-factory. Pop. (1870) 6760; (1890) 10,302.

Pituitary Body, a rounded body of the size of a small bean situated in the sella turcica in the sphenoid bone on the floor of the cavity of the skull. It contains small cavities lined by epithelium. It is not known to possess any function. It derives its name from its having been once supposed to secrete the fluid which is now known to be yielded by the Schneiderian or pituitary membrane of the nostrils (see NOSE). It is composed of two parts, the one a downgrowth from the floor of the third ventricle of the brain, the other an upgrowth from the pharynx, from which it has become completely separated. A disease called acromegaly is by some supposed to result from enlargement of this gland.

Pit Villages are collections of earth-caves, dug in the ground and covered with stones, wooden or wattle lids, or clay or sods of turf. They were used by prehistoric races or by races at the lowest stages of barbarism. A good example was unearthed during the latter half of the 19th century near St Mary Bourne, north-east of Andover, in north-western Hampshire. The pits are reached by entrance shafts, sloping downwards. The pits themselves are oval or pear-shaped, varying between 22 and 42 feet in length, and are about 12 or 13 feet wide, and 5 feet high, with the fireplace in the centre. Flint and bone implements and rude pottery have been found in them.

Pityri'asis (from the Greek word *pityron*, 'bran') is the term given to certain of the squamous or scaly diseases of the skin, in which there is a continual throwing off of bran-like scales of epidermis, which are renewed as fast as they are lost. It is most common on the scalp, when it is known as *dandriff*, and must be treated with weak alkaline lotions, or, if these fail, with diluted white precipitate ointment, provided there is no inflammation. *Pityriasis rubra* is a severe disease, affecting the whole or almost the whole body, and closely allied to, if not identical with, a severe form of dry Eczema (q.v.). *Pityriasis* or *Tinea versicolor* is due to the presence of a parasitic fungus, the *Microsporon furfurans;* it occurs in the form of irregular yellowish or brownish patches, confined to the parts of the body covered by the clothes. Microscopic examination of the exfoliated scales shows the spores and filaments of the fungus. The treatment of this affection must be solely local. Probably the best remedy is the application of a saturated watery solution of sulphurous acid gas, or of one of the sulphites dissolved in diluted vinegar, or of white precipitate ointment.

Pius, the name of nine among the Roman pontiffs, of whom the following only appear to call for particular notice.—PIUS II., originally known as Æneas Sylvius, was a member of the noble family of Piccolomini, and was born in 1405 at Corsignano near Siena. His early life was stained with moral irregularities, and, like other humanists of his time, he wrote licentious poems, letters, and at least one loose novel—*Lucretia and Euryalus.* At twenty-six he was employed as secretary to Domenico da Capranica, Bishop of Fermo, at the Council of Basel. He soon developed a genius for diplomacy, and from 1432–35 was employed in missions to Scotland, England, and Germany. Returning to Basel he sided with the council in its conflict with the pope, and on the election of the antipope, Felix V., was chosen as his secretary. But, having been sent on an embassy to the Emperor Frederick III., he was without difficulty induced to accept office in the imperial court, and served on several embassies and other missions of importance on behalf of the emperor. Up till this time he had lived a life of unrestrained self-indulgence, but at the age of forty his passions had burned themselves out, and he was able to take orders and make his peace with Rome—the only means of obtaining a reward adequate to his ambition. He won over Pope Eugenius IV. by the frankness of his apology and earned his gratitude by his adroitness in bringing back to the papacy the allegiance of the neutral German Church. Almost the last act of the pontiff was to reward him with the bishopric of Trieste. It was not, however, till the end of 1456 that Æneas was free to leave the uncongenial atmosphere of Germany. Nicholas V. had employed him without rewarding him, but Callistus III. created him a cardinal. On the death of Callistus in 1458 he was elected pope, and took the name of Pius II. He possessed a marvellous power of adapting himself to circumstances, and the profligate and shifty intriguer made a most decorous pope. He was embarrassed by contests about Neapolitan and German affairs, but his reign is chiefly memorable for his efforts to organise an armed confederation of Christian princes to resist the progress of the Turkish arms. He died at Ancona, 14th August 1464, his last moments darkened by the failure of his great scheme. Æneas Sylvius was one of the most eminent scholars of his age. His works were published at Basel (1 vol. fol. 1551), and consist chiefly of histories, or historical dissertations and materials of history. The most interesting of his writings, however, are his letters, which throw a vivid light upon their age. The same may be said of a biographical commentary, or rather autobiography, published under the name of the copyist Gobellinus, and apparently altered by his secretary Campanus.

See Voigt's *Life* (3 vols. Berlin, 1856–63); also two papers by Bishop Creighton in *Macmillan's Magazine*, vol. xxvii., and vol. ii. (1882) of his *History of the Papacy during the Reformation.*

PIUS IV., Giovanni Angelo Medici, was born of humble parents at Milan in 1499, was educated at Bologna, and under Paul III. rose rapidly to be Archbishop of Ragusa, vice-legate of Bologna, and cardinal (1549). He was elected pope at the close of 1559. His reign is chiefly memorable as that in which the protracted deliberations of the Council of Trent were brought to a close. The famous Creed of Pius IV., or Tridentine Creed, was confirmed by a bull dated 26th January 1564. Pius died, December 8, 1565, in the arms of his nephew, St Charles Borromeo. His Correspondence with the Emperor Maximilian II. has been edited by Schwarz (Paderborn, 1889).

PIUS V., originally named Michele Ghislieri, was born of poor parents, in the village of Bosco, near Alessandria, in 1504, and at the age of fourteen entered the Dominican order. His merit was

recognised by Paul IV., who named him Bishop of Sutri and Nepi in 1556, and cardinal in the following year. His austere temper prompted him as inquisitor-general for Lombardy to employ the most rigorous measures for repressing the Reformed doctrines. Under Pius IV. he was translated to the see of Mondovi, and was chosen unanimously as his successor, January 8, 1566. As pope he laboured to restore discipline and morality at Rome, reduced the expenditure of his court, prohibited bull-fights and other amusements, suppressed prostitution, and regulated the taverns of the city. He zealously maintained the Inquisition, and strove to enforce everywhere the disciplinary decrees of the Council of Trent. The whole spirit of his pontificate is most strikingly exhibited in the decree by which he ordered the yearly publication of the celebrated bull, *In Cœna Domini* (1568)—an attempt to apply to the 16th century the principles and the legislation of Hildebrand. His impotent bull releasing Queen Elizabeth's subjects from their allegiance (1570) fell harmless even upon patriotic English Catholics in a heroic age. But the most momentous event of the pontificate of Pius V. was the expedition which he organised, with Spain and Venice, against the Turks, and which resulted in the great naval engagement of the Gulf of Lepanto, on 7th October 1571. Pius died in the following May, 1572, and was canonised by Clement XI. in 1712.

Pius VI., originally named Giovanni Angelo Braschi, was born at Cesena, December 27, 1717. He was selected by Benedict XIV. as his secretary; and under Clement XIII. he was named to several important appointments, which led finally, under Clement XIV., to his elevation to the cardinalate (1773). On the death of Clement XIV. Cardinal Braschi was chosen to succeed him, February 15, 1775. His internal administration was enlightened and judicious. To him Rome owes the drainage of the Pontine Marsh, the improvement of the port of Ancona, the completion of the church of St Peter's, the foundation of the new Museum of the Vatican, and the general improvement and embellishment of the city. Soon after his accession he found himself at serious variance with the Emperor Joseph of Austria and Leopold of Tuscany, whose reforms had swept away much of the papal supremacy. The pope repaired in person to Vienna, but, though received kindly, failed to restrain the emperor from further curtailing his privileges. Soon after came the outbreak of the French Revolution and the confiscation of all church property in France. The pope launched his thunders in vain, and ere long the storm broke upon his own head. The murder of the French political agent Basseville in a street scuffle at Rome (1793) gave the Directory an excuse for the attack. In 1796 Bonaparte took possession of the Legations, and afterwards of the March of Ancona, and by a threatened advance upon Rome extorted from Pius, in the treaty of Tolentino (19th February 1797), the surrender of these provinces to the Cisalpine Republic, together with a heavy war contribution. The murder of General Duphot of the French embassy in December was avenged by Berthier marching on Rome and taking possession of the castle of St Angelo. Pius was called on to renounce his temporal sovereignty, and on his refusal was seized, February 20, and carried to Siena, and afterwards to the celebrated Certosa or Carthusian monastery of Florence. On the threatened advance of the Austro-Russian army in the following year he was transferred to Grenoble, and finally to Valence on the Rhone, where, worn out by age and grief, he died, August 28, 1799.

Pius VII., originally Gregorio Luigi Barnaba Chiaramonti, was born at Cesena, 14th August 1742. He entered the Benedictine order at an early age, taught philosophy and theology at Parma and at Rome, became Bishop of Tivoli, and on being created cardinal was translated to the see of Imola. After the death of Pius VI. Cardinal Chiaramonti was chosen his successor (March 14, 1800). Rome, which up to this time had been occupied by the French, was now restored to the papal authority, and in the July of that year Pius VII. entered into his capital; while next year the French troops were definitively withdrawn from the papal territory, with the exception of the Legations. Aided by his secretary, Cardinal Consalvi, Pius restored order in his states, and in 1801 concluded a *concordat* with Bonaparte. But much of the advantage thus gained by Rome was annulled simultaneously by Bonaparte's *Articles organiques*, which concerned the discipline of the church on marriage, on the clergy, and on public worship. These had never been submitted to the pope, and called forth his strongest opposition. In 1804 Napoleon compelled Pius to come to Paris to consecrate him as emperor. He was well received, but failed to get any modification of the articles, and not six months after his return to Rome the troops of Napoleon seized Ancona, and finally in February 1808 General Miollis entered Rome, and took possession of the castle of St Angelo. Ere long a decree was issued annexing the provinces of Ancona, Fermo, Urbino, and Macerata to the kingdom of Italy. The usurpation was consummated (May 17, 1809) by a decree annexing Rome and all the remaining papal territory to the French empire. The pope on June 10 retaliated with a bull of excommunication directed against the robbers of the holy see, yet without formally naming Napoleon. The unhappy pope was next removed to Grenoble, then to Savona, and finally to Fontainebleau. There he was forced into signing a new concordat, recognising the annexation of the Roman states to the empire (January 25, 1813). The fall of Napoleon allowed him to return, and on May 24, 1814 he re-entered Rome. The Congress of Vienna formally restored to him his territory, and the remainder of his reign was devoted, under the enlightened advice of Consalvi, to wise measures of internal administration. Brigandage was sternly suppressed, as well as secret societies, especially that of the Carbonari; while the Jesuits were restored, and concordats concluded with Naples, Prussia, Würtemberg, and other courts of Germany. Throughout his life Pius was a model of gentleness, simplicity, benevolence, and Christian charity. He died August 20, 1823, after having broken his thigh through a fall.

Pius IX., Giovanni Maria Mastai Ferretti, occupant of the papal chair during one of the most eventful periods in the history of the papacy, was the fourth son of Count Jerome Mastai Ferretti, and was born at Sinigaglia, May 13, 1792. His epileptic attacks rendered him unfit for the Noble Guard, whereupon he turned to the study of theology, and was admitted to deacon's orders in December 1818. For five years he presided over the orphanage of Tata Giovanni, next accompanied the Apostolic delegate Monsignor Muzi to Chili. In 1825 he returned to Rome, was made canon of S. Maria in the Via Lata, and head of San Michele, a great hospital for destitute children. In 1827 he was made Archbishop of Spoleto by Leo XII., and transferred to Imola by Gregory XVI. in 1832. In 1840 he became a cardinal, and on the death of Gregory XVI. in 1846 was elected by acclamation to succeed him. He was avowedly the leader of the reforming party, and twelve hours after his election Cardinal Gaysruck, Archbishop of Milan, reached Rome with instructions from Austria to

veto his election. He took the name of Pius IX., and entered at once on a course of reforms, by which he hoped to establish the papal government on a popular but yet firm basis. His first step was to grant an amnesty to all prisoners and exiles for political offences. He next removed most of the disabilities of the Jews, authorised railways, and projected a *Consulta* or council of state, and in March 1848 published his *Statuto Fondamentale*, a complete scheme for the temporal government of the papal states by means of two chambers, one nominated by the pope, the other (with the power of taxation) elected by the people. At first the new pope was the idol of the populace. Mazzini hailed the new policy with enthusiasm, and Carlyle declared that 'the old chimera was rejuvenised!' But the revolutionary fever of 1848 spread too fast for a reforming pope, and the refusal to make war upon the Austrians finally forfeited the affections of the Romans. On November 15, 1848, his first minister, Count Rossi, was murdered in broad daylight, and two days later a threatening mob assembled in the square of the Quirinal. On the 24th the pope escaped to Gaeta, a Neapolitan seaport near the Roman frontier. A republic was proclaimed in Rome, the provisional heads of which proceeded with great moderation and wisdom to a complete and radical remodelling of the civil government of the state. Pius from his exile addressed a remonstrance to the various sovereigns. In April 1849 a French expedition was sent to Civita Vecchia, and on July 2 General Oudinot took Rome, after a siege of thirty days. The papal government was re-established, but Pius himself did not return till April 12, 1850. From this time his government, swayed by Antonelli, was the very reverse of what it had been, and to the end of his life he continued an unhesitating and unyielding Conservative. After the war for the unification of Italy the Legations, Ancona, and a considerable part of the papal territory southward in the direction of Rome were annexed to the kingdom of Italy, but Pius persistently refused to cede any portion or to enter into any compromise.

In his ecclesiastical policy he was incessantly active, henceforward closely related with the Jesuits, and ever uncompromising in his ultramontanism; and at last he proceeded to promulgate dogmatic definitions about problems that had been left unsettled by the wisdom of the ages. He re-established the hierarchy in England, he sanctioned the establishment in Ireland of a Catholic university, and condemned the principles upon which the Queen's Colleges in that country were constituted. He concluded with Austria a concordat much more favourable to church authority than the existing ecclesiastical laws had permitted. By the bull 'Ineffabilis Deus' (8th December 1854) he decreed as a doctrine of the church the faith of the Immaculate Conception (q.v.) of the Blessed Virgin Mary; his famous encyclical 'Quanta Cura,' and the Syllabus, or list of prevalent errors especially to be reprobated, appeared in December 1864. But the most important event of his pontificate was the convocation of the Vatican Council, at which bishops from all parts of the Catholic world assembled in December 1869. It was adjourned in July 1870, after it had proclaimed the celebrated decree of the Infallibility (q.v.) of the Pope, when on a subject of faith or morals he issues a decree *ex cathedrâ* to the universal church. For the last ten years the pope's temporal power in Rome had been only maintained by French bayonets, and on the withdrawal of the garrison at the outbreak of the war with Germany the soldiers of Victor Emmanuel crossed the frontiers, and, after the short delay of a feeble and half-hearted defence, entered the city amid the acclamations of the populace, and so terminated the temporal power of the pope. The result of the *plebiscitum* on October 2 was 40,805 for, and but 46 against, union with Italy, and for the rest of his days the pope lived a voluntary prisoner within the Vatican, having the mortification to see his capital become the centre of a united kingdom of Italy, its king enthroned in the Quirinal with the affections of all his subjects. He renewed with all solemnity his oft-repeated protest, and refused the pension of £129,000 voted him by the national parliament. His loss was in some measure compensated by the revival, as a voluntary contribution, of the ancient tribute of Peter's-pence (q.v.). In June 1871 his reign reached the unparalleled duration of twenty-five years, and on June 3, 1877, he celebrated the jubilee of his episcopal consecration. He died a month after Victor Emmanuel (to whom he sent the papal benediction), on 8th February 1878.

See Lives by J. F. Maguire (2d ed. New York, 1878), T. A. Trollope (2 vols. 1877), and Wappmannsperger (Ratisbon, 1878); also the articles ITALY, GARIBALDI, and MAZZINI.

Pizarro, FRANCISCO, the conqueror of Peru, was the illegitimate son of a colonel of infantry named Gonzalo Pizarro, and was born at Trujillo in Estremadura, it is believed about 1470 or 1475. He received no education, and was not even taught to read and write, but entered the military service at an early age, and served under the 'Great Captain' (Gonsalvo di Cordova) in Italy. In 1509 we find him at Darien in the expedition of Alonzo de Ojeda. He also served under Vasco Nuñez de Balboa when he crossed the isthmus and discovered the South Sea, led an expedition as far as Biru, to the south of the isthmus on the Pacific coast, and eventually became a citizen of Panamá. In 1522 Don Pascual de Andagoya also reached Biru, and there collected information respecting the great empire of the Incas. Returning to Panamá to prosecute the discovery, he became so ill that he was induced by the governor to hand over the enterprise to three partners, Francisco Pizarro, another old soldier named Diego de Almagro (q.v.), and a wealthy ecclesiastic named Hernando Luque. Pizarro was to lead the expedition, Almagro was to keep open communications, and Luque was to supply the funds. Their first attempt was a failure, but in 1526 Pizarro and Almagro sailed in two vessels, with Bartolomé Ruiz, a very expert and gallant sailor, as pilot. Pizarro landed his men, Almagro returned to Panamá for supplies, and Ruiz made a voyage to the southward, being the first European to cross the equator in the Pacific Ocean. Almagro returned, and the expedition proceeded southwards. But they were not yet strong enough to form any settlement, and eventually Almagro was sent back for reinforcements, while Pizarro and part of the force remained on an island discovered by Ruiz, in 1° 57′ N., called Gallo. The arrangement caused much discontent. The men complained that they were being left to starve. The governor of Panamá refused to give any further countenance to an enterprise which seemed doomed to failure, and two vessels, under Pedro Tafur, were sent to bring the people back from Gallo. Pizarro refused to return. Drawing a line along the sand, he called upon those who remained resolute to achieve success in spite of all difficulties to come over to his side. Thirteen men crossed the line. Tafur returned with the rest to Panamá. Pizarro and his devoted little band removed to another island, called Gorgona, where there was more game and better water. For a long time the governor of Panamá refused to allow any help to be sent. At last Ruiz was allowed to sail with one small vessel. He reached Gorgona, and Pizarro embarked, full of

hope. Sailing southward they reached the Peruvian port of Tumbez, and collected full information respecting the empire of the Incas. Returning to Panamá, Pizarro proceeded to Spain to apply for authority to undertake the conquest of Peru.

The capitulation between Queen Juana and Pizarro was signed on 26th July 1529. Pizarro was made adelantado and captain-general, while Almagro received the title of marshal. Pizarro took back with him his four brothers, Hernando, Juan, Gonzalo, and Francisco Martin de Alcantara. He sailed from San Lucar on 19th January 1530, and from Panamá on 28th December 1531, with three vessels carrying 183 men and 37 horses. Almagro was to follow with reinforcements. Landing at Tumbez, the Spaniards commenced the march inland in May 1532, and on 15th November entered the city of Cajamarca. The Inca Atahualpa, after defeating his brother and ending a long civil war, was in the neighbourhood, on his way to Cuzco, the capital of the empire. Pizarro captured the native sovereign by treachery, and after extorting an enormous ransom, amounting to 4,605,670 ducats (£3,500,000 of our money), treacherously put him to death on 29th August 1533. The royal share of the treasure was sent to Spain, with tidings of the conquest. Pizarro then marched to Cuzco, and set up the young Inca Manco as nominal sovereign. On 6th January 1535 Pizarro founded the city of Lima, as the capital of his new government. He was created a marquis by the Emperor Charles V., while Almagro was empowered to occupy territory for 200 leagues from the southern boundary of Pizarro's government. But that southern boundary was not fixed. Almagro declared that Cuzco was within his grant, but was induced to forego his claim, and to undertake the conquest of Chili. The marquis was busy founding cities on the coast, while his brothers were at Cuzco, when a great insurrection of the Indians broke out. Both Cuzco and Lima were closely besieged, and Juan Pizarro was killed. For many months the Spaniards were in great danger, but in the spring of 1537 Almagro returned from Chili, raised the siege of Cuzco, and took possession of the city, claiming to be its lawful governor. The Marquis Pizarro had no intention of allowing his rival to retain Cuzco. Too old to take the field himself, he entrusted the command of his forces to his brothers, who defeated Almagro on 26th April 1538, and beheaded the old soldier soon afterwards. The property of his followers was confiscated. Pizarro remained at Lima, consolidating his power, and despatching various expeditions for discovery and conquest. But Almagro's followers were driven to desperation; they were called in derision 'men of Chili,' and the marquis treated them with contemptuous indifference. One of them, named Juan de Rada, matured a conspiracy for the assassination of the governor. The conspirators attacked his house during the mid-day meal, and murdered the old conqueror, who was between sixty-five and seventy, on 26th June 1541. The body of Pizarro was buried in the cathedral by stealth and at night.

Francisco Pizarro is one of the most prominent figures in the history of Spanish conquest in the New World. He was brave and determined, a man of inflexible constancy of purpose and infinite resource. His followers were devoted to his service, and some of his friendships endured until death. The indelible stain on his character is the treacherous execution of the Inca Atahualpa. Although without education, he rose to the greatness of his position, and proved himself to be an able and far-seeing administrator. Falling by the hands of assassins, he was defended by devoted friends, and died as bravely as he had lived. Pizarro was never married. By the Inca princess, Inez Huayllas Nusta, a sister of Atahualpa, he had two children—Gonzalo, who died young, and Francisca, who went to Spain with her step-father, Don Francisco Ampuero, a knight who married Inez after the assassination of the marquis. Francisca married her uncle Hernando Pizarro in 1551, and by him had three sons and a daughter. Hernando, for having beheaded the Marshal Almagro at Cuzco, was imprisoned in the castle of Medina del Campo on his return to Spain, where he remained until 1560. He married his niece during his imprisonment, which could not have been very rigorous. He died at Trujillo, the original home of himself and his brothers, in 1578.

Gonzalo Pizarro, brother of the Marquis Francisco Pizarro, served with his father in Italy when a boy. He accompanied his brother Francisco in the conquest of Peru, and did very good service when the Indians besieged Cuzco, and in the conquest of Charcas. In 1539 Gonzalo Pizarro undertook an expedition to the so-called Land of Cinnamon, the forest-covered region to the eastward of Quito. He left that city with 350 Spaniards and 4000 Indians on Christmas Day, and the hardships and sufferings endured by Gonzalo and his companions have seldom been equalled. Descending the rivers Coca and Napo, Gonzalo entrusted the command of a small vessel he had built to Francisco de Orellana, one of his lieutenants, who was to go in advance and seek for supplies. But Orellana deserted his starving comrades, discovered the whole course of the river Amazon, and returned to Spain. Out of the 350 Spaniards that left Quito 50 deserted with Orellana, 210 died of hunger and disease, and the miserable remnant returned to Quito with their intrepid leader in June 1542.

When Gonzalo Pizarro heard of the assassination of his brother the marquis he retired to his estates in Charcas. In 1544 the new viceroy, Blasco Nuñez Vela, arrived in Peru to enforce the 'New Laws.' The Spaniards were dismayed, and entreated Gonzalo to leave his retirement and protect their interests. He consented, chose an old veteran named Francisco de Carbajal as his lieutenant, and assembled a force of 400 men. The viceroy fled, and Gonzalo entered Lima in triumph on the 28th of October 1544 at the head of 1200 Spaniards, and several thousand Indians dragging the artillery. He was declared governor of Peru. Blasco Nuñez de Vela fled to Quito, but was closely followed by old Carbajal, and defeated and killed in the battle of Anaquito on January 18, 1546. Gonzalo Pizarro was undisputed master of Peru. Carbajal retired to Charcas to work the silver-mines.

When news of this revolt reached Spain the licentiate Pedro de la Gasca, an astute and very able ecclesiastic, was appointed to proceed to Peru as president of an 'Audiencia,' or court of five judges, and to restore order. He sailed in May 1546, and arrived at Panamá in August, where he gained possession of Pizarro's fleet by a combination of cunning and force. Gasca landed at Tumbez in June 1547. Gonzalo Pizarro, despairing of being able to make head against the president, determined to retreat into Chili. But there was a force, under an officer named Diego Centeno, hanging on his rear; and it was necessary to dispose of it first. Centeno was utterly defeated in the battle of Huarina, near the banks of Lake Titicaca, and the doomed Pizarro was so elated at the victory that he abandoned all idea of retiring into Chili. He advanced to Cuzco, and the President Gasca approached him by leisurely marches, encamping on the plain of Sacsahuana, near Cuzco, in April 1548. On the 9th Pizarro and Carbajal marched out of Cuzco, and both sides made ready for battle. But soon there were symptoms of desertion on

Pizarro's side. The desertions took place by companies and squadrons. So Gonzalo Pizarro sorrowfully took his way to the president's camp, and gave himself up. Carbajal was seized by the soldiers and hanged the following day. Gonzalo, the last of five famous brothers, was beheaded in presence of the whole army on the 10th of April 1548, at the age of forty-two. He left, by an Inca princess, a son known as Francisquito, who was made legitimate by the emperor in 1544, and a daughter named Inez, who was married in Lima. Francisquito was sent to Spain, but died young.

See Lives by Helps (1869) and Towle (Boston, 1878), also works cited at PERU.

Pizzicato, a phrase used in music for the violin or violoncello, to denote that here the strings are to be twitched with the fingers in the manner of a harp or guitar.

Placebo (Lat., 'I will please'), in the Roman Catholic service of vespers for the dead the name of the first antiphon, which begins with the word. In medicine it is an epithet applied to a remedy intended to humour or gratify a patient rather than to exercise any curative effect.

Place-names. See NAMES.

Placenta, or AFTER-BIRTH, the structure which unites the unborn mammal to the womb of its mother and establishes a nutritive connection between them. The placenta is peculiarly a mammalian structure, but it is not developed in Ornithorhynchus and Echidna, which lay eggs, nor is it more than incipient in the Marsupials, which bring forth their young after a short gestation. In all other mammals it occurs in various forms, partly embryonic in its origin, partly maternal, always acting as a double vascular sponge, by means of which the blood of the mother nourishes and purifies that of her unborn young. Vague prophecies of it occur in two cartilaginous fishes and in two lizards, in which there is a connection between the yolk-sac of the embryo and the wall of the oviduct.

In the hedgehog, which is a conveniently central type of mammal, the connection between embryo and mother has the following history. (*a*) The outer wall of the embryonic sac is moored to the wall of the uterus by small cellular outgrowths known as the preliminary 'villi,' and minute cavities between these are bathed by the blood of the mother. (*b*) The growing embryo becomes ensheathed by the double folds of the Amnion (q.v.), the inner parts of which form the 'amnion proper,' while the outer form the 'sub-zonal membrane.' Part of the yolk-sac wall fuses with this sub-zonal membrane; from the united area vascular villi grow out into the wall of the uterus, which is now much modified. Thus is formed a 'yolk-sac placenta,' as exhibited for a time by Insectivores and Rodents. (*c*) But the most important union between mother and offspring is that due to the union of Allantois (q.v.) and sub-zonal membrane. If there has been a yolk-sac placenta it dwindles before this new and more efficient union. From the united area vascular villi grow out into depressions or crypts in the uterine wall, part of which is modified into a spongy vascular tissue. In Insectivores, Bats, and Rodents the original outer wall of the embryonic sac persists between the placental villi and the maternal blood, and mediates between them.

The final placenta thus consists (1) of a maternal part—viz. a modified region on the wall of the uterus—and (2) of an embryonic part—viz. part of the allantois, fused to the sub-zonal membrane, and giving off vascular villi, between which and the maternal blood the persistent outer wall of the embryonic sac sometimes persists and mediates.

The term 'chorion' has been used in so many senses, that it seems advisable to abandon it. It is best applied to the union of sub-zonal membrane and allantois ('true chorion'), or to the union of sub-zonal membrane and yolk-sac ('false chorion').

The embryonic part of the placenta necessarily comes away at birth, and sometimes the vascular part of the maternal placenta is also discharged when the young is born. When this is the case, the placenta is called 'deciduate,' or better 'caducous.' When the maternal part of the placenta does not come away at birth the placenta is called 'indeciduate,' or better 'non-caducous.' Of non-caducous placentation two kinds are distinguished: *Diffuse*, when the villi are scattered over the surface of the embryonic sac (in Manis among Edentates, in the dugong, in Cetacea, in most Ungulates except Ruminants, in Lemurs); *Cotyledonary*, when the villi occur in patches (in Ruminants). Of caducous placentation three kinds are distinguished: *Zonary*, when the villi form a partial or complete girdle round the embryo (in Orycteropus and Dasypus among Edentates, in Elephants and Hyrax, in Carnivora); *Discoidal*, when the villi occur on a circular cake-like disc (in most Edentates, in Insectivores and Bats, in Rodents); *Meta-discoidal*, when the villi are at first scattered, but are afterwards restricted to a disc (in Monkeys and in Man). Sir William Turner, the 'grand-master of placental research,' allots the lowest place to such diffuse forms of placenta as that of the pig, but others maintain that the discoidal type as illustrated in the Insectivora is the most primitive. In Botany 'placenta' usually means the portion of the Ovary (q.v.) which bears the ovules. See also AMNION, ALLANTOIS, FŒTUS, MAMMAL.

Placenza. See PIACENZA.

Placitum Regium (called also *Placet*, *Exequatur*, *Lettres Patentes*) is an act or instrument executed in virtue of the privilege claimed by the government in certain kingdoms to exercise a supervision over the communications of the Roman pontiff with the clergy and people of those kingdoms, and to suspend or prevent the publication of any brief, bull, or other papal instrument which may appear to contravene the laws of the kingdom, or to compromise the public interest. The early Christian emperors, it is well known, freely extended their legislation into the affairs of the church; and one constant cause of conflict between church and state in the mediæval period was the attempt on the part of the sovereigns to control the free intercourse of the pope. In the Pragmatic Sanction in France, and in the similar legislation of Spain, Portugal, Sicily, and the Low Countries during the 15th century, the claims of the state are asserted; and among the so-called 'liberties' of the later Gallican Church (q.v.) was a certain subjection to the state in this particular. But it was in the German states that the claim was most formally embodied in the constitutional law. In England the statute of Præmunire (q.v.) was an example of the same tendency.

Placoid Fishes, an order of fishes, in the classification proposed by Agassiz, characterised by having *placoid* (Gr. *plax*, 'a broad plate') scales, irregular plates of hard bone, not imbricated, but placed near together in the skin. They are all Cartilaginous Fishes (q.v.). See SCALES.

Plagal. See PLAIN-SONG.

Plagioclase. See FELSPAR.

Plagiostom'ata. See CARTILAGINOUS FISHES.

Plague, a term used in the middle ages of all fatal epidemics indiscriminately, but now restricted

to a very malignant kind of contagious fever prevailing at certain times and places epidemically, characterised by buboes, or swellings of the lymphatic glands, by carbuncles and petechiæ, and apparently furnishing very imperfect security against its recurrence in the same individual.

The first extensive outbreak of this disease on record took place in the 6th century A.D., and devastated the whole Roman empire. It is supposed to have started from Lower Egypt: but from this time frequent epidemics occurred in Europe, culminating in the Black Death (q.v.) in the 14th century. It continued to ravage the north and west of Europe up till the 17th century. The last outbreak in England in 1663–65 caused the 'Great Plague of London,' and spread almost all over the country (see LONDON, Vol. VI. p. 699). Since the end of the 17th century it has only twice visited western Europe; in 1707–14 it spread from Russia and Hungary as far as Sweden, Denmark, Prussia, and Bavaria; and in 1720–22, being introduced from Syria into Marseilles, it destroyed almost half the population there, and spread through Provence. During all this time its most constant seats, so far as is known, were the countries bordering the Eastern Mediterranean—Lower Egypt, Syria, Asia Minor, and Turkey in Europe. But from all these it has meantime disappeared. The last cases known in Egypt occurred in 1844, and in the others in 1841. It was hoped that the disease had become extinct, but since then it has occurred more than once in Arabia, Tripoli, Persia, and Mesopotamia, and in 1878 it spread to south-east Russia. It has been present in India at least since 1815, sometimes in epidemics (e.g. the 'Páli plague,' 1836–38), but most constantly in districts on the southern slopes of the Himalayas; and it is said to be always found in some parts of China. An outbreak at Hongkong in 1894 was followed by the fearful visitation at Bombay (q.v.) and India in 1896–1901, and reached (in a mild form) even Lisbon and Glasgow in 1900.

It is the most destructive of all known epidemics. Rarely less than 60, sometimes 90 per cent. of those attacked die. 'It often carries off half the population of a town or of a district in which it prevails, and it may completely root out whole families, so that no survivor remains.' The Black Death of 1348–50 is believed to have destroyed not less than a quarter of the population of Europe.

The general symptoms resemble those of other severe fevers: shivering, rise of temperature, aching in head, back, and limbs, sickness, &c. Great weakness succeeds, with mental disturbance leading to coma or delirium. Death often occurs before any characteristic symptoms are developed; but at an early stage dark spots or patches often appear on the skin, produced by subcutaneous hæmorrhages (petechiæ, ecchymoses), and bleeding may also take place from the various mucous membranes. Bleeding from the lungs, though rare in recent epidemics, was regarded as a characteristic symptom of the Black Death in its most virulent form. About the second or third day the most distinctive features of the disease are developed—viz. one or more buboes or glandular swellings, usually in the neck, armpits, or groins: these generally break and lead to prolonged suppuration. In a few cases they are absent altogether. Carbuncles not frequently develop at a later stage of the disease. Good nursing, good nourishment, free stimulation, and early opening of the buboes are helpful. Yersin's inoculation with prepared serum proved useful in the Bombay epidemic of 1896–98. There can be no doubt that it is a highly infectious disease, and that the infection may be conveyed by clothes, bedding, &c., as well as by direct contact with the sick. In all epidemics it has been observed that the unhealthy conditions produced by poverty and filth are extremely favourable to the disease, and that it has been much less prevalent and severe among those in comfortable circumstances and healthy surroundings.

See Hecker's *Epidemics of the Middle Ages* (published by the Sydenham Society, 1844); Hirsch's *Geographical and Historical Pathology* (vol. i., New Sydenham Society, 1883); and the articles BLACK DEATH, EPIDEMIC.

Plaice (*Pleuronectes platessa*), a common flatfish in the same genus as the flounder. It usually inhabits sandy and muddy banks off the European coasts from France to Iceland. Like the flounder, it may pass from estuaries into rivers, and can even thrive in fresh-water ponds. It often lies slightly covered with sand, but with the eyes exposed and watchful for prey. The food consists of molluscs, crustaceans, and worms, but especially of the first. It spawns in early spring, and is in best condition about the end of May. It was once a common belief that shrimps were the parents of plaice! The plaice is taken both by lines and trawl-nets, is in considerable esteem for the table, and is plentiful in the British markets. Those from sandy ground are said to be much more palatable than those from the mud. Compared with the flounder, the plaice is rather broader in proportion to its length. The general size weighs about 2 to 3 pounds, but much larger specimens are often caught; the coloured side is predominantly olive-brown with orange spots, but the colour changes rapidly in precise harmony with that of the ground on which the fish rests; six blunt tubercles extend from the eye to the beginning of the lateral line, which has an almost straight course.

Plaid. See HIGHLANDS.

Plain, a geographical term which hardly admits of precise definition. It is generally applied to extensive tracts of approximately level or undulating country, which occur at less than 1000 feet above the sea. Broad areas of similar character at higher elevations are usually termed *Tablelands* (q.v.) or *Plateaus*. This is the general rule, but when the surface of a plain slopes gradually upwards to heights of several thousand feet, the whole tract is still called a plain. As an example may be cited the great plains east of the Rocky Mountains, which fall imperceptibly away towards the east from an elevation of 6000 feet or so. Among the most characteristic plains are the wide alluvial lands of the greater rivers. But the term is extended to such low-lying regions as central Ireland, the Midlands of England, middle Europe, &c.—regions which have no great elevation and present a gently undulating surface, interrupted now and again by isolated hills, and lines of cliffs and escarpments. From the same point of view the whole interior of North America lying between the Rocky Mountains in the west and the Alleghany and White Mountains in the east, and extending from the Gulf of Mexico to the shores of the Arctic Ocean, may be called a plain. So likewise more than half of Europe is a plain that is continued into Asia and extends northward over vast regions of that continent. Plains necessarily differ much in appearance according to the nature of soil and climate, from the dreary, sandy wastes of north Africa to the luxuriant fertility of the South American silvas. Wide regions of comparatively level ground in each of the great continents have acquired various names, such as the *Steppes* and *Tundras* of eastern Europe and Asia, the *Deserts* of Arabia and Africa, the *Savannahs* and *Prairies* of North America, and the *Llanos, Pampas,* and *Silvas* of South America. See DESERT.

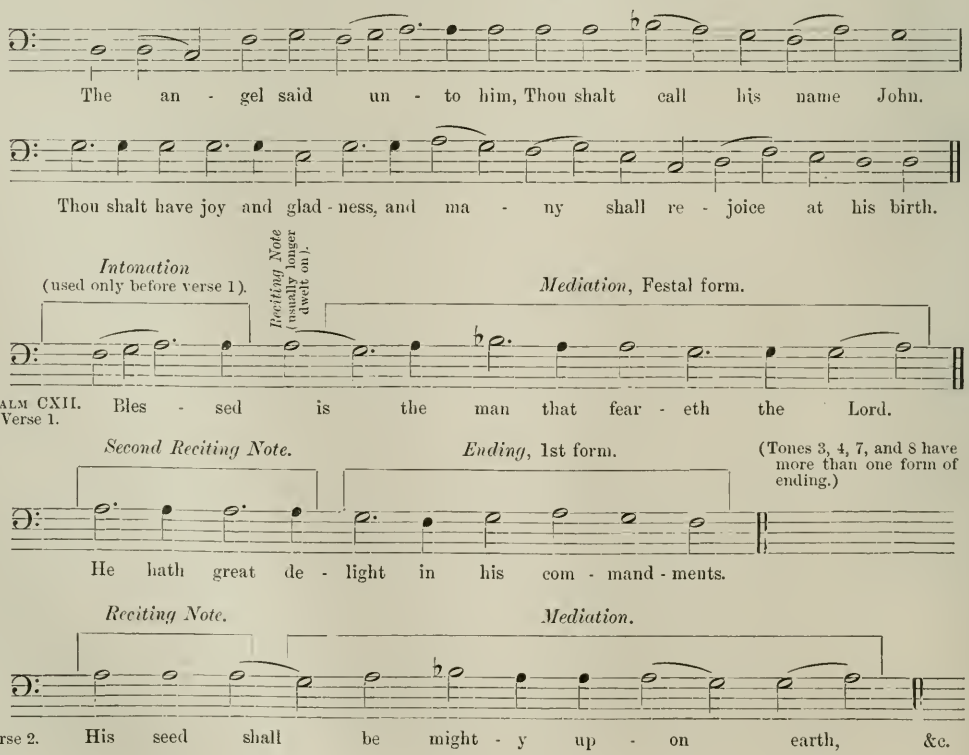
Plainfield. a city of New Jersey, on Green Brook, 24 miles by rail WSW. of New York, many of whose business men have their homes here.

Clothing, hats, and machinery are manufactured. Pop. (1860) 3224; (1890) 11,267.

Plain-song, Plain-chant, Gregorian Chant, or Gregorian Music, is the music used in the Christian church of the West from the earliest times, still in use in all Roman Catholic churches, and extensively revived since the rise of the High Church party in the English Church. Many good musicians, however, consider its interest as antiquarian rather than musical. Its distinguishing points are (1) its recitative-like character, as opposed to what was styled *musica mensurata*—i.e. *barred* music, with a marked and regular rhythm, which was the essential point of ancient Greek music, and more or less of nearly all modern music; (2) the *modes*, or scales, in which it is written, which are more numerous and varied than the modern major and minor; and (3) its being (originally) sung in unison, though much of it is susceptible of treatment in harmony, and is now frequently so heard. It used to be stated also that the notes in it were all of equal length, but this view is now generally repudiated and condemned. It embraces music for all parts of the Roman services, from the *Accents* (nearly in monotone) proper to the various readings to the more elaborate melodies of the antiphons and hymns, and the various parts of the mass. The best known and most ancient of all is the music of the eight Tones sung to the Psalms, commonly called the Gregorian Tones. As to the origin of these many different views prevail, some ascribing them to a Greek, some to a Hebrew source, others to the early Christians; there seems some probability, though there is no direct evidence, that they were actually derived from the music of the temple service. As at first plain-song was handed down orally only, and the early systems of notation were very defective, it is impossible to determine how far it may have been corrupted. It was first reduced to system by St Ambrose (died 397), but much more extensively by St Gregory the Great, towards the end of the 6th century. There have of course been large additions since. How he noted the music is uncertain; the early notation and rules of plain-song were so complicated that it is said ten years' study were necessary to acquire a mastery of them. Local varieties of the proper melodies gradually sprang up, almost every diocese having an office-book peculiar to itself—e.g. the antiphonary and gradual of Sarum, said to be one of the purest. The earliest known existing record of plain-song is the Antiphonarium, or rather Gradual, in the library of the monastery of St Gall in Switzerland, probably of the 9th or 10th century. Various directories have been published, notably that begun by Palestrina and finished by Guidetti; the latest, issued under sanction of the pope, is the great series published at Ratisbon by Pustet, beginning in 1871 with the Gradual. The music is still always printed in the old square notes on a stave of four lines. At the Reformation the Gregorian music was adapted to the new vernacular services of the English Church by John Marbeck, who published in 1550 *The Book of Common Praier noted*; and his arrangement is still in use in cathedral services. Anglican Chants (q.v.) are modelled on the Gregorian psalm tones.

The modes, or scales, of plain-song require some explanation. Their variety has been acknowledged by first-rate authority as affording greater resource of expression than our major and minor modes; and music has been written in them by great modern composers—e.g. the 'Hymn in the Lydian Mode' in Beethoven's Quartet, op. 132. They

SPECIMEN OF ANTIPHON, LEADING TO A PSALM, SET TO THE FIRST TONE, FROM THE RATISBON 'VESPERAL,' TRANSLATED AND IN MODERN NOTATION.



The an - gel said un - to him, Thou shalt call his name John.
Thou shalt have joy and glad - ness, and ma - ny shall re - joice at his birth.
Intonation (used only before verse 1).
Reciting Note (usually longer dwelt on).

Psalm CXII. Verse 1.
Bles - sed is the man that fear - eth the Lord.
Second Reciting Note.
Ending, 1st form.
(Tones 3, 4, 7, and 8 have more than one form of ending.)
He hath great de - light in his com - mand - ments.
Reciting Note.
Mediation.
Verse 2.
His seed shall be might - y up - on earth, &c.

were derived from, though it is not certain that they were identical with, the Greek diatonic scales, after which they have been named. The principle of their formation is that each of the seven natural sounds of the diatonic scale forms the keynote, or 'final' of a mode, which embraced that note and the seven above it. (The melodies rarely exceeded an octave, and no flats or sharps are found except an occasional B flat.) This would give us seven modes; but to each of these is attached another, in which the melody, while having the same final or keynote, instead of ascending to the octave above, ranges from the fourth below it to the fifth above. The former are called the *authentic* modes, the latter *plagal*. The difference of the modes, and the effect of the melodies in them, is owing, it will be noticed, to the various positions of the two semitones in the scales. The difference between an authentic and a plagal melody may be illustrated from two psalm-tunes—Newton or New London, and the Old Hundredth, in the first of which the melody lies between the keynote and its octave, but in the other between the fourth below and the fifth above the keynote. But while the whole fourteen modes are enumerated, for the sake of completeness in theory, two of them are universally rejected in practice as defective—the two having B as their keynote. The modes are, then, arranged in pairs as follows. The 1st or Dorian (authentic) embraces the notes from D on the middle line of the bass stave to the D above, and has its keynote on D; the 2d or Hypo-dorian (plagal) has the same keynote, but its compass is from the A below to the A above it; the 3d or Phrygian (authentic) and its corresponding plagal mode, the 4th or Hypo-phrygian, have similarly their keynotes on the E of the third space of the bass stave; the 5th or Lydian and 6th or Hypo-lydian have F for final; the 7th or Mixo-lydian and 8th or Hypo-mixo-lydian have G; the 9th or Æolian and 10th or Hypo-æolian end on A; then come the rejected modes on B, styled the Mixo-locrian and Hypo-mixo-locrian; then the Ionian or Iastian and Hypo-ionian or Hypo-iastian on C, numbered variously as 11th and 12th, or 13th and 14th, according to the rejection or inclusion of the two preceding. The Ionian is the modern major mode. St Ambrose's arrangement of the melodies was said to have been confined to the 1st, 3d, 5th, and 7th modes (authentic); while the relative plagal modes, 2d, 4th, 6th, and 8th, were added by St Gregory. In these are written the correspondingly numbered eight psalm tones; the Peregrine Tone, used only for the psalm *In exitu Israel*, is in the 9th mode. The other modes were finally added in the 8th century under Charlemagne. Each mode has its reciting note, or Dominant—not to be confounded with the modern term in harmony.

Various specimens of plain-song hymn melodies will be found in *Hymns Ancient and Modern*—e.g. No. 14, the vesper hymn of St Ambrose, 'O Lux beata Trinitas;' and No. 96, the hymn of Fortunatus, 'Vexilla Regis prodeunt,' which may be studied in a different treatment by Gounod in the 'March to Calvary' in his *Redemption*.

See the Rev. Thomas Helmore's *Manual*, *Brief Directory*, and *Primer* of Plain-song; various articles by Mr W. S. Rockstro in Grove's *Dictionary of Music;* and the *Magister Choralis*, by Rev. F. X. Haberl (trans. by Rev. N. Donnelly, Ratisbon, 1877). An edition of the official Roman *Directorium* was printed in 1874, also at Ratisbon, by Pustet. See also the article HARMONY.

Planarian, a term practically co-extensive with Turbellarian, and applicable to the members of the lowest class (Turbellaria) of worm-like animals. They live in fresh and salt water and sometimes in damp earth. They are unjointed 'worms' with a ciliated skin; the food-canal is often branched, but has no posterior opening; from the simple brain two lateral nerves extend backwards; the body-cavity is undeveloped; there are no respiratory or circulatory organs; the excretory system consists of branching tubes ending in ciliated cells; all but two genera are hermaphrodite. Their simplicity is well illustrated by the fact that some multiply by dividing into two, while a fragment of others may re-grow the whole. In *Microstoma lineare* a temporary chain of eight or sixteen individuals is sometimes formed by budding. In diet they are carnivorous, but a few are parasitic—suggesting the next class of Trematodes. As illustrative genera we may note Planaria, in fresh water; Vortex and Convoluta, with green species (the colour being probably due to partner Algæ); Gunda, with hints of segmentation; Microstoma and Stenostoma, the two unisexual genera; Graffilla and Anoplodium, parasitic; Bipalium and Geodesmus, on land; Cœloplana and Ctenoplana, in some ways suggestive of the Cœlenterate Ctenophora.

Planché, JAMES ROBINSON, playwright, archæologist, and herald, was born in London, 27th February 1796, the son of a watchmaker of Huguenot descent. His first extravaganza, *Amoroso*, was produced at Drury Lane Theatre in 1818, and others soon followed. In 1823 he designed for Charles Kemble the dresses and appointments for the play of *King John*, and afterwards for other Shakespearian productions. In 1824 he wrote English words for Weber's *Der Freischütz*, and in 1826 for *Oberon;* and in the period following 1831, when he was engaged by Madame Vestris at the Olympic, nearly 200 dramatic pieces came from his pen—the most adaptations, but a large number original dramas (e.g. *Charles XII.*) and extravaganzas. Of the latter five volumes were published in 1880. In 1843 he helped to found the British Archæological Association, and for many years he contributed valuable papers to the proceedings of the Society of Antiquaries. In 1854 he was made Rouge Croix Pursuivant, and in 1866 Somerset Herald; in 1872 he received a civil list pension of £200 a year. He died 29th May 1880.

Among Planché's works, besides two histories of British costume and a *Cyclopædia of Costume*, are his *Introduction to Heraldry* (18th ed. 1866); *Regal Records, or a Chronicle of the Coronations of the Queens Regnant of England* (1838); *The Pursuivant of Arms* (3d ed. 1874); and *The Conqueror and his Companions* (2 vols. 1874). See his *Recollections and Reflections* (2 vols. 1872).

Planchette, a thin heart-shaped piece of wood mounted on three props, two of which are furnished with castors, and one is a pencil which may be made to trace characters on a sheet of paper by resting the fingers upon the instrument, and thus almost insensibly steering it in any direction required. Its use is as a supposed medium for spiritualistic communications; and it is obvious with what ease an instrument so sensitive to movement may be manipulated so as to startle the credulous into belief. See, however, the *Proceedings of the Psychical Society* (1888, &c.).

Plane (*Platanus*), the sole genus of trees of the natural order Platanaceæ. The species of plane are few; natives of temperate climates in the northern hemisphere; tall trees, with deciduous large palmate leaves and smooth whitish bark, which annually scales off in large pieces.—The Oriental Plane (*P. orientalis*), a native of Greece and the East, was planted by the Greeks and the Romans as an ornamental tree, no other tree, indeed, commanding equal admiration; and for centuries the youth of Greece assembled under its shade in the groves of Academus to receive lessons in philosophy. The plane is still planted for shade

and ornament in the south of Europe. Many fine trees exist in England, but they were at one time much more numerous, great part having died in the end of the 18th century. The spring frosts and the insufficient duration of the summer for the proper ripening of the wood render Scotland less

Fig. 1.—Oriental Plane (*Platanus orientalis*): *a*, branch; *b*, flower, and *c*, fruit, on larger scale than *a*.

suitable for its cultivation, yet there is a tree at Gordon Castle 66 feet high. No tree better endures the atmosphere of a large city, and there are no finer trees within the precincts of London than its plane-trees. Noble specimens are to be seen in Hyde Park and Russell Square, in London, and the avenue of the Thames Embankment is formed with this tree. In the East the plane attains an immense size. One tree in the meadow of Buyukdere, on the banks of the Bosporus, is 141 feet in circumference at the base, extends its branches 45 feet from the trunk, and is believed to be more than 2000 years old. The wood of the plane, when young, is yellowish white; when old it is brownish, fine grained, takes a high polish, and is esteemed for cabinet-making. A rich alluvial soil and the vicinity of water are most

Fig. 2.—Branch of *Platanus occidentalis*.

suitable to this tree. The North American Plane, or Buttonwood (*P. occidentalis*), is a very similar tree. It is the largest deciduous tree of the United States, and abounds on the banks of the great rivers of the middle states. Its timber is not very valuable, and is very liable to decay. A tree of this species on the bank of the Thames, in Chelsea Hospital gardens, is 115 feet high, with a trunk 5 feet in diameter.—The name plane-tree is commonly given in Scotland to what in England is known as the Sycamore (*Acer pseudo-platanus*), which resembles the true planes in its foliage, but is neither a plane nor a true sycamore, being really the Greater Maple. See MAPLE.

Planetarium. See ORRERY.

Planetoids, or ASTEROIDS, are now usually known as Minor Planets. See PLANETS.

Planets (Gr. *planētes*, 'a wanderer') are those heavenly bodies (including the earth) which belong to our solar system, and revolve in elliptic orbits round the sun. They are often denominated *primary planets*, to distinguish them from their moons or satellites, which are called *secondary planets*. The name planet is of considerable antiquity, and was applied to these dependents of the sun to distinguish them from the myriads of luminous bodies which stud the sky, and which present to the naked eye no indication of change of place (see STARS). The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the Earth, Mars, the Planetoids (q.v.), Jupiter, Saturn, Uranus, and Neptune. Six of these, Mercury, Venus, the Earth (which was not, however, then reckoned a planet), Mars, Jupiter, and Saturn, were known to the ancients; Uranus was discovered by Sir William Herschel (q.v.) in 1781; and Neptune, after having its position and elements determined theoretically by Leverrier and Adams, was discovered by Professor Challis and Dr Galle in 1846. The Planetoids, of which some 300 are now known, have all been discovered since January 1, 1801. Six of the planets, the Earth, Mars, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, almost all the Planetoids, and all the satellites except the Moon are invisible to the naked eye. The visible planets can be at once distinguished from the fixed stars by their clear steady light, while the latter have a sparkling or twinkling appearance. The planets, as observed from the Earth, move sometimes from west to east, sometimes from east to west, and for some time remain stationary at the point where progression ends and retrogression commences. This irregularity in their movements was very puzzling to the ancient astronomers, who invented various hypotheses to account for it. See PTOLEMAIC SYSTEM. The system of Copernicus, by assuming the sun, and not the earth, as the centre of the system, explained with admirable simplicity what seemed before a maze of confusion.

The planetary orbits differ considerably in their degrees of eccentricity, the Planetoids, Mars, and Mercury being most, and the larger planets least eccentric. No two planets move exactly in the same plane, though, as a general rule, the planes of the larger planets most nearly coincide with that of the ecliptic. The latter are consequently always to be found within a small strip of the heavens extending on both sides of the ecliptic; while the others have a far wider range, Pallas, one of them, having the angular elevation of its orbit no less than 34° 42″ above the ecliptic. According to Kepler's Laws (q.v.), the nearer a planet is to the sun the shorter is the time of its revolution. The arrangement of the planets in the solar system bears no known relation to their relative size or weight, for though Mercury, Venus, and the Earth follow the same order in size and distance from the sun, yet Mars, which is farther from the sun, is much less than either the Earth or Venus, and the Planetoids, which are still farther off, are the least of all. Jupiter, which is next in order, is by far the largest,

being about 1½ times as large as all the others together; and, as we proceed farther outwards, we find Saturn less than Jupiter, and Uranus than Saturn, though Neptune, the remotest, is somewhat larger than Uranus.

With reference to their distance from the sun, as compared with that of the Earth, the planets are divided into *superior* and *inferior;* Mercury and Venus are consequently the only 'inferior' planets, all the others being 'superior.' The inferior planets must always be on the same side of the Earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a *transit* (see SUN) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight. The time which elapses from one conjunction to its corresponding conjunction is called the *synodic period* of a planet, and in the case of the inferior planets must always be greater than the true period of revolution.

Fig. 1.—Diagram showing the comparative sizes of Sun and Planets.

Mercury, the planet which is nearest the sun, is also, with the exception of the Planetoids, the smallest (being only three times the bulk of the moon), and performs its revolution round the sun in the shortest time. Its greatest elongation is never more than 27° 45′, and consequently it is never above the horizon more than two hours after sunset, or the same time before sunrise; on this account, and from its small apparent size (5″ to 13″), it is seldom distinctly observable by the naked eye. It shines with a peculiarly vivid white or rose-coloured light, and exhibits no spots. Its year (or sidereal period of revolution round the sun) is 87·969 days.

Venus, the next in order of distance and period, is to us the most brilliant of all the planets. Its orbit is more nearly a circle than any of the others, and when at its inferior conjunction it approaches nearer the Earth than any other planet. Its apparent angular dimensions thence vary from 10″ at the superior to 66″ at the inferior conjunction. Its greatest elongation varies from 45° to 47° 12′, and therefore it can never be above the horizon for much more than three hours after sunset, or the same time before sunrise. While moving from the inferior to the superior conjunction Venus is a *morning star*, and during the other half of its synodic period an *evening star*. When this planet is at an elongation of 40° its brilliancy is greatest, far surpassing that of the other planets, and rendering a minute examination through the telescope impossible. At this period it sometimes becomes visible in the daytime, and after sunset is so bright as to throw a distinct shadow. Astronomers have repeatedly attempted to ascertain the nature and characteristics of its surface, but its brightness so dazzles the eyes as to render the correctness of their observations at best doubtful. From the changes in the position of dusky patches on its surface, which have been frequently noticed, it is concluded that it revolves on its axis, and that its equator is inclined to the plane of its orbit at an angle of 75°; but many astronomers doubt these conclusions. Its year is 224·7 days. Professor Schiaparelli has shown reason for believing that both Mercury and Venus always present the same face to the sun. Both Venus and Mercury necessarily exhibit phases like the moon. For *transits* of Venus, see SUN.

The *Earth*, the next planet in order, will be found under its own name; it has a single satellite, the *Moon* (q.v.). Its year is 365·256 days.

Mars, the first of the superior planets, is much inferior in size to the two previous, its volume being about ⅐th of the Earth's, and, after Mercury, its orbit is much more eccentric than those of the other planets. When it is nearest to the Earth (i.e. in opposition) its apparent angular diameter is 30″; when farthest from it (i.e. in conjunction), not more than 4″. Mars revolves on its axis (which is inclined at an angle of 28° 27′) in 24 hours 37 minutes, and its year is 687 days long. In 1877 Hall of Washington discovered that it had two satellites, now named Phobos and Deimos. It shines with a fiery red light, and is a brilliant object in the heavens at midnight when near opposition; when seen through the telescope its surface appears to be covered with irregular blotches, some of them of a reddish, others of a greenish colour, while at each pole is a spot of dazzling white. The red spots are surmised to be land; the green, water; but the markings on Mars appear to have changed considerably since they were first observed. The white spots at the poles are with some reason supposed to be snow, since they decrease when most exposed to the sun, and increase under the contrary circumstances. The Phases (q.v.) of Mars range between full, half, full (in conjunction, if visible), and half.

The Planetoids.—After Mars in order come the *Planetoids* (see below), formerly but improperly called Asteroids.

Jupiter, the next in order, is the largest of all the planets, its bulk being more than 1400 times that of the Earth, though, from its small density, its mass is only 300 times more. After Venus it is the brightest of the planets and the largest in apparent size, its angular diameter varying from 30″ to 50″.

When looked at through a telescope it is seen to be considerably flattened at the poles, owing to its rapid revolution on its own axis; and its surface is crossed in a direction parallel to its equator by three or four distinct and strongly-marked belts, and a few others of a varying nature. Spots also appear and remain for some time on its surface, by means of which its revolution on its axis has been ascertained. Separate spots give, however, slightly different periods (some even move past one another), but a period of 9 hr. 55 min. 21 sec. is generally accurate. Jupiter has five satellites —the fifth discovered by Barnard at Lick Observatory in 1892. The four discovered by Galileo, easily observable through an ordinary telescope, have rendered immense service in the determination of longitudes at sea, and of the motion and velocity of light. They were proved by Sir William Herschel to revolve on their own axes in the same time that they revolve round their primary. The smallest is about the same size as our Moon, the others are considerably larger. The year of Jupiter is 4332·584 days.

Saturn, next in position, is about 745 times larger in volume, though only about ninety times greater in mass, than the earth. Its apparent diameter when in opposition is 20·3″, and there is a considerable flattening towards the poles. Its surface is traversed by dusky belts much less distinctly marked than those of Jupiter, owing doubtless in great part to its inferior brightness; its general colour is a dull white or yellowish, but the shaded portions, when seen distinctly, are of a glaucous colour. The most remarkable peculiarity of Saturn is its ring, or series of concentric rings, each one parallel and in the same plane with the others and with the planet's equator. The ring

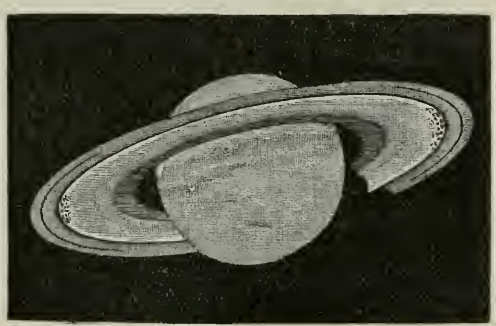

Fig. 2.—Saturn, as observed by Trouvelot with the 26-inch Washington Refractor.

is *distinctly* separable into three parts; the two outermost are bright like the planet itself, while the innermost (called the 'Dusky' or 'Crape' ring) is of a purplish colour, and is only discernible through a powerful telescope. They are most probably composed of a multitude of small satellites in rapid revolution round the planet. They are not always visible when Saturn is in the 'opposite' half of its orbit, for when the plane of the rings (whose outer diameter is 166,920 miles) passes between the Earth and the Sun, their dark surface is turned towards us, and when the sun is in their plane only the narrow edge is illumined: in both of these cases the ring is invisible from the Earth. Its plane being inclined at an angle of 28° to the ecliptic, we see the two surfaces of the ring alternately for periods of fifteen years at a time; and at the middle of each period the rings attain their maximum obliquity to the ecliptic, and are then best seen from the Earth. It is hardly necessary to remark that at the end of each period they become invisible. Saturn has also no less than eight satellites, seven of which revolve round it in orbits little removed from the plane of the ring, while the eighth, which is the second in size, is considerably inclined to it. Two of the satellites were discovered by Herschel in 1787 and 1789, four by Cassini in 1672 and 1684, one by Huyghens in 1655, one by Mr Lassell in England and Professor Bond in America in 1848. The satellites are all situated outside of the ring, and the largest of them is nearly equal to the planet Mars in size. The year of Saturn is 10,759·219 days.

Uranus, the next planet in position, was discovered accidentally by the elder Herschel on 13th March 1781, and was named 'the Georgium Sidus' and 'Herschel,' but these names soon fell into disuse. It is about seventy-two times greater than the Earth in volume, and thirteen times in mass; but, though so large, its distance is so much greater in proportion that astronomers have been unable to gain much information concerning it. No spots or belts have hitherto been discovered on its surface, and consequently its time of rotation and the position of its axis are unknown. It is attended by a number of satellites, but so minute do these bodies appear that astronomers hitherto have been unable to agree as to their exact number; Sir William Herschel reckoned six, while other astronomers believe in the existence of four, five, and eight respectively. That there are at least four is beyond doubt. The year of Uranus is 30,686·820 days.

Neptune is the next and outermost member of the solar system, and, at a distance of nearly 3000 millions of miles from the centre of the system, slowly performs its revolution round the sun, accomplishing the complete circuit in about 165 solar years. It is about ninety times larger than the Earth, but from its extreme remoteness is of almost inappreciable magnitude when seen through an ordinary telescope. It was the disturbance in the motion of Uranus caused by the attractive force of this planet which led Leverrier and Adams to a calculation of its size and position, on the supposition of its existence: and the directions which were given by the former to Dr Galle of Berlin, specifying its exact position in the heavens, led that astronomer to its discovery on 23d September 1846 (see ASTRONOMY). Mr Lassell of Liverpool discovered that Neptune is attended by one satellite. The satellites of Uranus and Neptune differ from the other planets, primary and secondary, in the direction of their motion, which is from east to west, and in the case of the former in planes nearly perpendicular to the ecliptic. Both Uranus and Neptune were observed long before the times of Herschel and Leverrier, but they were always supposed to be stars. Uranus is known to have been observed by Flamsteed between 1690 and 1715, and Neptune by Lalande in 1795.

In astronomical tables, almanacs, &c. the planets are for convenience denoted by symbols instead of their names, as follows: Mercury, ☿; Venus, ♀; Earth, ⊕; Mars, ♂; the Planetoids, in the order of their discovery, ①, ②, ③, &c.; Jupiter, ♃; Saturn, ♄ or ♄; Uranus, ♅; Neptune, ♆ or ♆; the Sun, ☉; the Moon, ☾.

MINOR PLANETS, the name given to that numerous group of very small planets which is situated in the solar system between Mars and Jupiter. Till the 19th century they remained undiscovered; but for some years before their existence had been suspected, mainly owing to the remarkable hiatus in the series of the planetary distances when compared with the law of Bode (q.v.). On 1st January 1801 the first of them (Ceres) was detected by Piazzi of Palermo, and his success roused his brother astronomers to search for more planets. Their search was success-

ful, for Olbers (q.v.) discovered two (Pallas and Vesta) in 1802 and 1807, and Harding one (Juno) in 1804; but, as all researches for some time subsequent to 1807 were unavailing, astronomers gradually allowed themselves to settle down into the belief that no more planetoids remained to be discovered. But the detection of a fifth (Astræa) by Hencke in 1845 revived the hope of fresh discoveries, and from this period no year (excepting 1846) has passed without adding to the list. The number known at the beginning of 1851 was 13, of 1861 was 62, of 1871 was 112, of 1881 was 219; in 1898 there were 430. This great success of the astronomers of our time is due to the systematic manner in which the zodiacal belt has been explored, and the place and apparent size of every star of this region distinctly determined; so that the presence of a wandering body can at once be detected. Among the most successful of the discoverers of planetoids have been Palisa of Vienna, and C. H. F. Peters (1813–90) of Hamilton College, U.S. The former, since 1872, has discovered more than 80, on one occasion as many as 5 in a week; while the latter, after 1861, discovered 48.

The magnitudes of these celestial bodies have not been accurately ascertained, but it is certain that they are exceedingly small as compared even with Mercury, the least of the other planets; the diameter of the largest among them being generally believed not to exceed 450 miles, while most of the others are very much smaller than this. They also differ, generally speaking, from the rest of the planets in other respects; their orbits are of greater eccentricity, are inclined to the ecliptic at a greater angle, and are interlaced in a most intricate manner, crossing each other so frequently as to form, when viewed perpendicularly, a kind of network. The consequence of this is that a planetoid which is nearest the sun at one part of its orbit is, when at another part of its orbit, farther from it than are several of the others, and a mutual eclipsing of the sun at different periods by two planetoids must be of very frequent occurrence. The mean orbit of the first 251 planetoids coincides, however, within 30′ with that of Jupiter. Of the planetoids of which the elements had by 1891 been satisfactorily calculated, Medusa (No. 149) has the shortest period of revolution, 1137·69 days, and Hilda (No. 153) the longest, 2869·92 days. The corresponding mean distances from the sun, expressed in parts of the earth's mean distance, are respectively 2·13275 and 3·95228. Till 1876 the extremes known in this respect were Flora and Sylvia respectively. The nearest approach to the sun is made by Phocea (perihelion distance, 1·787). Freia recedes farthest from him (aphelion distance, 4·002). Polyhymnia's orbit has the greatest eccentricity, amounting to 0·33998; Lomia's the least, 0·2176. Massalia's orbit makes a smaller angle—only 41′ 7″—with the ecliptic than that of any other planet in the solar system, while the inclination of the orbit of Pallas is no less than 34° 42′ 41″. After the first two or three of these bodies had been discovered the opinion was propounded by Olbers that they were but the fragments of some large planet; and this hypothesis received corroboration from the intimate connection which was shown to subsist among them; but of late years it has fallen out of favour with astronomers. Some infer that the planetoids are best accounted for by the nebular hypothesis. It has been calculated that the combined mass of all the planetoids cannot exceed one-fourth of the earth's mass.

For a Table of the periods, distances, size, density, &c. of the planets, see SOLAR SYSTEM. See also PHOTOGRAPHY, and SPECTRUM.

Plani'meter, a machine for measuring areas on a plane. The best-known form is that of Professor J. Amsler-Laffon of Schaffhausen, the theory of which will be found discussed in Williamson's *Integral Calculus*, and in Minchin's *Uniplanar Kinematics*. It consists of two rods hinged together. The extremity of the one rod is fixed, so that the free extremity of the other is able to trace out any form of curve limited only in size by the dimensions of the apparatus. The theory of the instrument depends upon the fact that, as the free end is made to trace out the boundary of any closed area, the hinged end oscillates to and fro along a curve, but traces out no area. Rigidly attached to the rod whose one end traces out the plane area is a graduated roller fixed with its axis of rotation parallel to the line joining the hinge and the tracing point. As the closed curve is being described the roller rotates because of the lateral movement of the rod; and the difference of the readings before and after the tracing has been accomplished gives a number proportional to the area that has been gone round. To Amsler-Laffon also is due a more elaborate form of integrator capable of measuring moments of inertia of areas. It greatly facilitates the calculation of displacements, metacentres, and curves of stability in naval designing.

Plantagenet, the surname of an Angevin family which in 1154 succeeded in the person of Henry II. to the throne of England on the extinction of the Norman dynasty in the male line, and reigned till 1485, when the battle of Bosworth gave the crown to the family of Tudor. The name was first adopted by Geoffrey, Count of Anjou, husband of Matilda, the daughter of Henry I., from the badge of a sprig of broom (*planta genista*) which he wore in his bonnet; and Henry I. is the only king to whom Mr Freeman would allow the name. The Plantagenet kings were Henry II., Richard I., John, Henry III., Edward I.–III., Richard II., Henry IV.–VI., Edward IV.–V., and Richard III. See the separate articles on these names; also, for the great struggle between its two rival branches, the article ROSES (WARS OF THE). Miss Norgate's *England under the Angevin Kings* (2 vols. 1887) is an altogether admirable history of the Plantagenet period as far as the reign of John.

Greater Plantain (*Plantago major*).

Plantain. For the tropical plantain (*Musa*), see BANANA. The English plant so called belongs to the Plantagineæ or Plantaginaceæ, a natural order of exogenous plants, mostly herbaceous and without stems; the leaves forming rosettes, flat and ribbed, or taper and fleshy; the flowers usually in spikes, and generally hermaphrodite; the calyx 4-parted, persistent; the corolla hypogynous, membranous, persistent, its limb 4-parted; the stamens four, inserted into the corolla, with

long filaments; the ovary free, of a single carpel, 1—4-celled; the cells containing one, two, or many ovules; the fruit a membranous capsule with a lid. The *testa* of the seeds abounds in mucilage, which is easily extracted by boiling water. There are about 120 known species, diffused over all parts of the globe, but most abundant in temperate and cold countries. The most important genus is Plantago, the species of which often receive the English name Plantain. Five of this genus are found in the United Kingdom, the chief of which are the following: the Greater Plantain, or Waybread (*Plantago major*), one of the most common of British plants; a perennial, with broad ovate stalked leaves and long cylindrical spikes, growing in pastures, waysides, &c. It is very widely diffused over the world. Its seeds are a favourite food of birds, and the gathering of the spikes to feed cage-birds is familiar to every one. The leaves are applied to wounds by the peasantry in many districts. They are said also to be a useful application to ulcers and indolent scrofulous tumours. —The Ribwort Plantain, or Ribgrass (*P. lanceolata*), is another very common British plant, forming no small part of the herbage of many meadows and pastures, and sometimes sown by farmers, but with doubtful wisdom. Its leaves are lanceolate, and taper at both ends; its spikes are short, ovate or cylindrical, and placed on long angular stalks. Its seed is acceptable to cage-birds. This is the plant commonly known as 'bullies,' or 'sodgers,' the striking off the heads (or spikes) of which is such a favourite amusement of children.—The mucilage of the seeds of *P. ispaghula* and of *P. psyllium* is much used in India in catarrhs and other complaints; and *P. psyllium*—called Fleawort, and its seeds Fleaseed—is cultivated in France for the sake of this mucilage, which is used by paper-stainers in preference to that obtained from linseed, and is also extensively used by muslin manufacturers for stiffening their goods. The plant has a branched spreading stem, and recurved leaves.

Plantain-eaters (*Musophagidæ*), a family of Pie-like birds, of African distribution, arboreal habits, and vegetarian diet. The species of Musophaga are bluish black, the Turacous (Turacus) are light green with carmine wing-feathers. This occurrence of a green pigment (turacoverdin), as distinguished from a green colour, is unique among birds, and the carmine pigment (turacin) is also interesting because it seems to be partially washed out during the rainy season.

Plantation. See ARBORICULTURE. 'His Majesty's Plantations' was a not unusual term in the 17th and 18th centuries for the British settlements in America, to which it was customary to transport offenders, political and other, till the American Revolution. See PRISONS, TRANSPORTATION.

Plant-houses are garden structures designed for the protection and cultivation of the plants of warmer climates than our own. Apart from the style of architecture, a plant-house must be so constructed as to admit a maximum of light to the interior; there must also be ample provision for ventilation, and means for maintaining such atmospheric temperature as is necessary to the plants that are to be cultivated in it. Glass, wood, and iron are the materials of which plant-houses are made. Masonry is not essential in the erection of plant-houses, but it is very generally employed to give stability, durability, and architectural effects. Glass obviously is the most important material: the larger the amount of it that enters into the structure of a plant-house the better adapted will it be for the cultivation of plants; the means for securing the maximum of light is thereby provided, and its regulation is then under the control of the cultivator.

Under the term plant-house is included every kind of horticultural glass erection employed in the culture of flowering and ornamental plants, as distinguished from those which are devoted exclusively to the culture of fruit-trees or other plants that are grown solely for the sake of their fruit. They are broadly divided into three classes —viz. hothouse or plant-stove, intermediate house, and greenhouse. The structure of each class may be the same in all respects except in the power of the heating apparatus. In the hothouse it must be adapted to create and sustain tropical temperatures irrespective of the temperature of the outer air; in the intermediate house the heat of extra-tropical and temperate countries must be provided; and in the greenhouse all that is required of the heating apparatus is the exclusion of frost or the maintenance of a minimum temperature of 40° F. Hothouses are either dry or moist, according to the class of plants to which each may be devoted; the natives of dry tropical regions and those of maritime lake and river districts severally requiring special adaptations in connection with the heating apparatus for providing atmospheric humidity. Thus there may be tropical orchid-houses, tropical fern-houses, tropical aquatic-houses—the latter being fitted with tanks of heated water, in which Victoria regia, Nymphæas, and other aquatic plants of the tropics are cultivated; but the more common class of stove is that in which the internal arrangements are made with the view of accommodating a large variety of plants, having considerable diversity of constitutional requirement. The intermediate house may be subdivided in the same way into the cool orchid-house, the cool fernery, &c.; but more commonly it is adapted to the wants of miscellaneous plants, and very often indeed it is used temporarily for tropical plants during their period of rest, when a lower temperature and less humidity than those of the stove are desirable. The greenhouse may be a heath-house if exclusively devoted to the culture of Cape heaths (Erica) and kindred plants, or it may be a New Holland house, if its inhabitants are chiefly composed of the interesting natives of New Zealand, Tasmania, and other temperate parts of Australasia.

The conservatory is a plant-house in which a miscellaneous collection of plants, after having been grown elsewhere, is placed in order to display the beauty of flowers and foliage. It may be either cool or hot, according to the classes of plants accommodated in it. Being usually a place of resort, or a lounge accessible from the drawing-room or some other part of a mansion, its architectural features should be in harmony with those of the building of which it forms a part; but due regard should also be had, in deciding upon architectural details, to the providing of ample light, and the means of securing perfect ventilation. The propagating house is a plant-house devoted to the purpose of rearing the several classes of plants indicated in the foregoing, either by seeds, cuttings, grafting, or any other mode that may be required in particular cases. It may be heated or cool, and differs from the ordinary plant-house chiefly in being more restricted in atmosphere. It is fitted with close glass-cases, fixed or portable, for the purpose of preventing exhaustion, by the atmosphere, of cuttings and other subjects temporarily destitute of roots. An essential feature of the internal arrangements of the propagating house is a bed or beds filled with sand, cocoa-nut fibre, or any other cleanly material, in which the pots containing cuttings may be plunged at will, to prevent evaporation from their sides and fluctuations of

temperature in their contents. These beds are usually provided with hot-water pipes, tanks, or flues below, for the purpose of giving bottom heat when required.

See also FORCING, GARDENING, HOTBED, ORCHIDS, PEACH, VINE, &c.; S. Wood, *Forcing Gardening* (1881); Fawkes, *Horticultural Buildings* (new ed. 1886); Rivers, *The Orchard House* (1881); and other works by Baines (1885), Hibberd (new ed. 1880), May (new ed. 1888), and Williams (new ed. 1883).

Plantigrades. See BEAR, CARNIVORA.

Plantin. CHRISTOPHE, an eminent printer, was born at St Avertin, near Tours, in 1514, and settled as a bookbinder at Antwerp in 1549; some six years later he began to print. The books that came from his office are distinguished for their accuracy and beautiful workmanship and finish. His business prospered, and he had often twenty presses or more in active operation at once. The most noted of all his publications is the *Biblia Polyglotta* (8 vols. 1569–73), which was printed under the personal superintendence of Arias Montanus, the court chaplain of Philip II. of Spain. Plantin's editions of the Bible in Latin, Hebrew, and Dutch, and editions of the Greek and Latin classics, are scarcely less celebrated. He died at Antwerp, 1st July 1589. He had set up printing-establishments in Leyden and Paris, and these, with that in Antwerp, were carried on by the husbands of his daughters. His office in Antwerp remained in the possession of the family of John Moretus, his son-in-law, until it was bought by the city in 1876 for 1,200,000 francs; out of it was created the 'Musée Plantin' (1877).

See Life by Max Rooses (in French, Antwerp, 1882); Backer and Ruelens, *Annales de l'Imprimerie Plantinienne* (Brussels, 1865); Degeorge, *La Maison Plantin* (3d ed. Paris, 1886); and *Correspondance de Plantin* (edited by Rooses, Ghent, 2 vols. 1884–86).

Plant-lice. See APHIDES.

Plants. It is not possible to frame a complete definition of a plant as opposed to an animal; the most obvious distinction is that a plant is fixed, while an animal moves; and though it is quite true that plants form that kingdom of nature which is characteristically passive in its life, while the animal life is more vigorous, yet there are many animals, such as a sea-anemone, which are as fixed as a plant; and all plants are sensitive to the sun's rays, and move in response. Nor can we make a formal distinction between them in terms of the food they require; for although it is true that plants live upon simple unorganised materials, the salts and water of the soil, and the carbonic acid and oxygen of the air, and indeed serve as the source of all food for animals, yet there are many parasitic plants which live on the juices of other living creatures. What chiefly makes such a definition impossible is that at the bottom of the ladder of life there are innumerable living creatures which it is a mere formality to call either plants or animals. From such creatures as these it is possible that the two great kingdoms of nature have been evolved step by step in constantly diverging lines. But the diversity of nature of plant and animal life is such that they are mutually helpful to each other; plants having the means of feeding upon the carbonic acid of the air, using the carbon and giving out the oxygen, thus forming matter for the life of animals, who in return, by breathing out carbonic acid, help to keep the air in a fit state for plants. This mutual relation of the two kingdoms finds another expression in the aid that insects and some birds give to the higher plants, for in their search for honey they become covered with pollen, and carrying it from flower to flower secure cross-fertilisation; while it is probable that the bright colours of flowers have been to a certain extent evolved by the natural selection which the insects who visited them have exerted, by going more often to those of the brighter colour.

For the classification of plants and list of allied subjects, see BOTANY; for their life-processes, see VEGETABLE PHYSIOLOGY; see also the articles AGRICULTURE, BIOLOGY, CULTIVATED PLANTS, FIBROUS SUBSTANCES, FLOWER, GARDENING, and those on the great groups of plants—ALGÆ, CONIFERÆ, CYCADS, FERNS, FUNGI, &c.

MOVEMENTS OF PLANTS. The movements of plants may be divided into (1) those that take place during growth, including growth itself, many of which are common to all plants; and (2) those that may be seen in mature plants—these are rather the exception than the rule. The whole matter is fully treated in the article on Vegetable Physiology (q.v.); here a short and general account will be given.

Growth, in its rate and direction—the direction being really determined by the relative rate of various parts—is influenced by many factors; the effects of temperature, light, gravitation, and moisture are well marked.

Temperature.—There is a certain temperature at which growth is most rapid, also a minimum and a maximum at which it ceases; these points are different for different plants.

Light.—The formation of chlorophyll and therefore of starch depends, in nearly all cases, upon light, but that light generally retards *growth* may be seen by the long stems of plants grown in the dark, and by the bending of plants grown in a window towards the light. In a few cases, as in the older parts of the stems of ivy, growing parts turn away from the light. The rays towards the blue end of the spectrum are the most powerful in their effect upon the direction of growth.

Gravitation.—Stems generally grow upwards and roots downwards; that this is an effect of gravitation is proved by the following experiments. Place a seedling in a horizontal position; the growing tip of the stem will turn upwards and that of the root downwards. Rotate a plant slowly in a vertical plane, so as to cause the direction of gravitation to alter constantly; the direction of the growth of stem and root is irregular. Rotate a plant very rapidly, so as to introduce the so-called centrifugal force; the stem will grow towards the centre, that is, in the direction *opposite* to that of the acting force, and the root away from it, that is, *in* the direction of the acting force.

Moisture.—Roots always grow in the direction of the greatest moisture. This effect is a stronger one than that of gravitation, for if seeds germinate in a sieve filled with damp sawdust the roots at first grow downwards until they have grown through the sawdust out into the dry air; then the direction of growth changes, and the tips bend round and grow up again into the damp sawdust.

'Spontaneous' Movements of Growing Plants.—There are other movements of growing parts the causes of which are not well understood. Thus, the leaves of a young bud are kept close together, bent over the tip of the stem, by the more rapid growth of their under than of their upper surfaces. When the bud is older the upper surfaces of the leaves begin to grow more quickly than the under surfaces and the leaves unfold. Such movements are spoken of as nutations. The tips of climbing stems describe a 'circumnutation' due to successive alterations in the rate of growth of the sides of the stem. It is in virtue of these movements that such plants are able to climb by twining round a support. Tendrils have similar movements, but there are further complications (see VEGETABLE PHYSIOLOGY). All these movements are due to unequal growth of the parts of the plants.

The Movements of Mature Plants which we have now to describe are due to alterations in the turgidity of the cells. The exciting stimulus of some of these movements is known: it may be contact, light, temperature; in other cases it is obscure, as we have found to be the case with some of the movements of growing plants.

Contact.—The leaves of the Sensitive Plant (q.v.) droop when touched or shaken; the stamens of the Berberidaceæ, when touched, bend down and come in contact with the stigma. The tentacles of Drosera bend over, and the leaflets of Venus' Fly-trap close, when an insect alights upon them (see INSECTIVOROUS PLANTS).

Light and Temperature.—Many leaves—e.g. those of Mimosa and Oxalis—move up and down with variations of light and temperature. The sleeping and waking of plants—i.e. the folding of many leaves and flowers at dusk and their opening in the morning—are familiar examples of the effect of variations in external conditions.

Spontaneous Movements of Mature Plants.—The leaves of some few plants—e.g. the *Hedysarum gyrans*—rotate in the dark, while the leaves of Mimosa, Oxalis, and Trifolium move up and down. These movements are not seen in daylight, probably because they are obscured by the movements due to light. The movements of the leaflets of *Desmodium gyrans* are dealt with at TELEGRAPH PLANT. The plasmodia of Myxomycetes creep, Bacteria and Diatoms move in a way not yet understood, Volvox swims by means of cilia, the zoospores of Algæ and the antheroids of Mosses and Ferns swim after they have been set free.

MEDICINAL PLANTS.—The study of plants with genuine or fancied curative properties is as old as human thought and sickness. Even animals seek such medicines, and it must be remembered that our early ancestors were much more familiarly acquainted with fruits and seeds, roots and bulbs than are their more carnivorous descendants. But, while it may be contended that ancient medical treatment was in great part a natural return to more primitive vegetarian diet, it is obvious that men would be quick to profit by a wide and often costly experience of plants with special properties, poisonous and emetic, tonic and narcotic, excitant and sudorific. While botanical science is partly rooted in the garden, no small part of it has grown out of a primitive materia medica. Thus, in the writings of Hippocrates (460–377 B.C.) and those to which his name is extended 236 medicinal plants are recorded; the list swells in the works of Aristotle (387–322 B.C.) and Theophrastus (371–286 B.C.), while the 'Materia Medica' of Dioscorides (born in the 1st century A.D.) includes the names and partial descriptions of about six hundred. His work remained authoritative for fifteen centuries, and was continued on the one hand through the herbalists like Gerard and Culpepper into the botanical side of the modern pharmacopœia, on the other hand through such early botanists as Cæsalpinius into the independent—doubtless too independent—science of botany.

In connection with medicinal plants there are many interesting chapters of history with which the student should make himself acquainted—the weird stories of the old traffic in vegetable poisons; the magicians' use of narcotics and excitants; the mystical doctrine of Signatures (q.v.), according to which plants bore signs indicative of their virtues; the gradual decay of herb gathering and the loss of much of the ancient traditional lore; the persistent record of the old uses of plants in both technical and popular names, such as Pulmonaria, Sanicula, Tussilago, and wound-wort, scurvy-grass, gout-weed; the additions to the British flora by such importations as belladonna; the elimination from the modern pharmacopœia of many vegetable drugs whose value was only fanciful; the relegation of others to the list of spices; the modern discovery or rediscovery of the potencies of Calabar bean, cinchona, coca, and many more.

See BOTANY, MATERIA MEDICA, PHARMACOPŒIA; Woodville, *Medical Botany* (4 vols. 1793); Hayne, *Beschreibung der in Arzneikunde gebräuchlichen Gewächse* (1805–46); Nees von Esenbeck, Weihe, Walter, and Funke, *Sammlung der officinellen Pflanzen* (1821–33); Bentley and Trimen, *Medicinal Plants* (4 vols. Lond. 1877); Luerssen, *Medicinisch-Pharmaceutische Botanik* (Leip. 1877).

DISEASES OF PLANTS (*Phytopathology*). Scientific investigation of the diseases of plants has not till recently been so widely and systematically followed up as the economic importance of the subject deserves. Our knowledge, therefore, of the causes and of the conditions of disease in the vegetable kingdom is comparatively limited and imperfect. Enough is, however, known to establish the general conclusion that, though there is in many cases a close analogy between the diseases of plants and animals, the causes of disease are very different in their nature in the main. While bacteria and the allied Schizomycetes are recognised as the active agents in the development of disease in animals, parasitic fungi are now regarded as the chief cause of disease in plants. Wet rot in the potato, rot in the bulbs of the hyacinth and the onion, gummosis in the tomato, yellows in the peach, and pink decay in wheat may be cited as the principal diseases of plants at present ascertained to be caused by bacteria.

Parasitic fungi are extremely numerous, and are as varied in their action and peculiar in the parts they affect as they are numerous. Some attack the roots, others the stem and branches, while the flowers and even the several organs of reproduction and the fruit are each liable to be attacked by some particular parasite which induces disease. They are almost always local in their action, and it is very rare to find a case in which the whole organism of a plant is affected in the sense that man and other animals are said to be constitutionally diseased. Instances there are in varieties of cultivated plants of something extremely like constitutional proneness to disease. Certain varieties of peas and of wheat are extremely liable to mildew, and to become abortive or die of the affection. But such extreme cases are regarded as evidence rather of local or temporary conditions being favourable to an overwhelming distribution of the parasite and the consequent multiplication of the lesions than of the permeation of disease which takes place in the organism of animals on the introduction of a microbe into the blood.

Nor is heredity so generally recognised as a factor in predisposing plants to disease as it is ascertained to be in animals. The tendency already alluded to in some varieties of peas and wheat, and a similar tendency to canker in some varieties of the apple, and the greater liability of certain varieties of the potato to succumb to disease than others, would indeed appear to be attributable to hereditary predisposition in the individual kinds. But it is generally conceded that such peculiarities are indications only of constitutional weakness in the variety, not of any hereditary proneness to disease.

In the suddenness of outbreak and the rapidity with which they spread when they first appear in a country or locality, there is a strong resemblance in some plant diseases to certain epidemics in animals. And this resemblance is carried further in tracing the subsequent history of notable plant diseases. They appear, like epidemics in animals, to exhaust their extreme virulence after a time. The cases of attack may continue numerous and

frequent, but the type is less severe, the disease wears itself out. The potato disease of 1845 has continued annually in greater or less severity since that time; but from that year, and the two or three years immediately succeeding, it has ceased to be so formidable. Other instances might be mentioned in illustration of this resemblance of remarkable plant diseases to epidemics among animals—the vine disease (*Oïdium*), the hollyhock disease (*Puccinia malvaccarum*), the celery disease (*P. Apii*), all of which made their appearance suddenly with such virulence and widespread rapidity as to threaten extinction of the species attacked, but are now sources of neither trouble nor alarm.

The direct action of parasitic fungi in causing disease in plants is through the mycelium or spawn injuring the host plants either by depriving them of nourishment, by impairing their power of assimilation, or by abnormally accelerating or retarding growth. The extent of injury inflicted is extremely variable, in some cases exterminating in degree, and in others, though widespread and general, having little ill effect upon the health of the subjects. Adverse external circumstances—such as unsuitable temperature, excess of dryness or moisture in the air and in the soil, deficiency of light, the presence of deleterious elements in the soil or of noxious gases in the atmosphere—by debilitating the plants render them more liable to attacks of fungi, and aggravate their severity.

The effects of disease in plants are extremely various. One of the most common manifestations of the presence of parasitic fungi in the tissues is *hypertrophy* in the parts affected. This may be either local or general; the roots, the stems, the leaves are all liable to this peculiar disorder. Many of the conifers are particularly subject to hypertrophies in disease. The so-called *Cedar-apples* of the United States, which occur in great abundance on the branches of *Juniperus virginiana*, are caused by the spawn of *Gymnosporangium macropus*. They are reniform tumours, and, as has been pointed out by Professor Farlow, originate by the mycelium entering a leaf and growing downwards into the bark of the smaller branches. Its presence acts as a source of irritation to the cells. The stem and branches of *Juniperus communis* are subject to hypertrophies caused by the spawn of *G. claviariæforme*. This is frequently to be observed in Britain, and the enlargements are of a very persistent character, and in effect impede the supply of sap to the branches beyond them. Similar tumours occur on the branches of the silver fir, which are caused by the spawn of *Peridermium elatinum*. But the most remarkable example of hypertrophy in connection with the diseases of any of the conifers is that which occurs in the larch disease, which is caused by the spawn of *Peziza calycina*. The presence of the spawn threads in the cortex, cambium, and woody tissues causes their death; but hypertrophy of the tissues of the surrounding parts is set up. The death and fissuring of the bark of the affected parts follows in due course, and the branch attacked eventually dies, and sooner or later also the tree succumbs to the disease. There are many other examples of this form of plant disease, nor are they peculiar to ligneous plants, but occur in humble herbaceous subjects, such as the violet, garden and other species of anemone, ranunculus, and even in grasses; but space will not permit of more extended notice of particular cases.

'Finger-and-toe,' 'Anbury,' and 'Club-root' are the common names given to a disease which attacks the turnip, cabbage, cauliflower, and other members of the important natural order of Cruciferæ. It assumes the form of tumours on the roots generally, but they also appear on the bulb of the turnip. They increase in number and in size as the plants grow, but eventually the plants cease to develop and die; the tumours becoming fœtid masses, and leaving the spores of the fungus (*Plasmodiophora brassicæ*) in the soil.

Diseases of plants of traumatic origin are those which result as a consequence of wounds which may have been received by a tree or shrub. Nature may have succeeded in covering over the wound, and superficially all may appear well: but it often occurs that some fungus, perhaps harmless to the subject while its bark is intact, finds a lodgment in the wound, and sets up parasitic disease.

Canker, though most familiar to us upon the apple-tree, is not uncommon upon such trees as the oak, ash, elm, beech, &c. It is caused by the same fungus (*Nectria ditissima*) in every case. Gummosis, which is similar to canker, is caused by *Gleospora gummifera*, which occurs in several forms. This destructive disease, it has been suggested, was caused by bacteria, but Beyrinck has conclusively settled the point by inoculative experiments. It is quite innocuous when inoculated into other trees, such as the apple, pear, oak, and maple.

Some parasitic fungi cause disease and death by fastening on the woody tissues of trees and shrubs when these are exposed by reason of wounds and bruises of the bark. The spawn penetrates gradually to the core of even the largest trees, and effects their decay and death. Unlike the microscopic species which induce disease by penetrating the herbaceous parts of plants, these wound parasites are mostly large conspicuous fungi. Examples are to be found on the ash and the elm in *Polyporus squamosus*, and in two species of Agaricus, *A. ulmarius* and *A. adiposus*, the latter attacking wounded ash and beech trees, and the former wounded elm-trees, while *A. ostreatus* attacks injured laburnums.

Rot or gangrene in the stems of fir-trees is caused by *A. melleus*, the mycelium of which finds its way into the woody tissues by the roots and gradually ascends the trunk, inducing decay either in the form of moist or dry rot.

Atrophy occurs in the pine, in wheat, and in other plants in consequence of attacks of various minute parasitic fungi. *Uredo pinitorquum* attacks the pine tribe, and by arresting the flow of sap at the points attacked starves the branches beyond, causing sterility and eventually death. In like manner *Puccinia graminis* attacks the straw of wheat, and renders the ear abortive. But sterility is also caused by parasitic fungi attacking the organs of reproduction directly. Certain species attack the male organs only, as *Ustilago violaceu*, some, such as *Thecaphora hyalina*, affect only the female organs, while *Ustilago carbo* effects the destruction of all the floral organs.

A singular feature in the economy of many of the minute parasitic fungi is that in one stage of their existence they are capable of living only on one kind of host plant, and at another stage on a species quite distinct: so distinct indeed, as in the case of the Puccinia above named, that in one form it attacks the barberry and in another stage wheat. It has long been a matter of common observation among farmers in Britain, on the continent of Europe, and in parts of the United States, where the common barberry has been introduced, that the proximity of that shrub to wheat-fields had some mysterious connection with mildew in wheat. In the state of Massachusetts a law was passed in 1760 enjoining the extirpation of the shrub, in consequence of the belief that it caused or at least intensified the wheat disease. The problem was solved by the late Professor De Bary in 1864, who,

by placing the promycelial spores of the Puccinia (wheat-mildew) on the barberry produced *Æcidium berberidis*, the mildew which frequently attacks that shrub. Since that time De Bary, Hartig, Plowright, and others have demonstrated that sixty or more species of these minute parasites have this heterocismal habit, and further investigation will doubtless reveal many more.

Cures for plant diseases are as yet empirical rather than scientific. In many cases the subject affected is fatally smitten before evidence of disease is visible. Mildew, which is one of the most common phenomena of plant disease, is the fructification, the final stage, of the parasite. The mycelium, whence the mildew springs, is working its deadly function on the plant in parts which external remedial applications cannot effectively reach. In many cases of plant disease the affected subject dies without any apparent cause; investigation after death may discover it, but too often also it reveals the fact that our knowledge does not enable us to prescribe a cure. Internal remedies and the means of exhibiting them are yet undiscovered. Soot, sulphur, soap are safe external remedies for mildew—that is, they destroy the pest without injuring the foliage on which it preys—but do not always eradicate the disease. *London Purple* and *Paris Green*, both having copper for their base, are very effectual external remedies, but require to be used with great caution, as they are dangerous to plant-life. There are many other preparations and compounds obtainable which are more or less effectual in destroying parasitic fungi, but the only safeguard against attack appears to be the maintenance of the plant in perfect health. By intelligent culture—that is, by surrounding the plant with those conditions of soil and atmosphere essential to its healthy existence—disease may be prevented, except it is epidemic or all-pervading, as in the case of the potato disease.

There are separate articles in this work on plant-diseases at Anbury, Ergot, Raphania, Rust, Smut, and under the names of the plants affected—e.g. Potato; and on the various insect-pests which induce diseased conditions, such as the Aphides and Phylloxera. See also Parasitic Plants; Sorauer, *Handbuch der Pflanzenkrankheiten* (2d ed. 1886); Frank, *Die Krankheiten der Pflanzen* (1880); Hartig, *Lehrbuch der Baumkrankheiten* (1882); Coste, *Phytotomie Pathologique* (1877); J. Paget, *Elemental Pathology* (1880); Professor H. Marshall Ward, *The Diseases of Plants* (1889); and Professor Plowright in the *Gardeners' Chronicle* for 1891.

Plant-lore. Apart altogether from the more or less vague and valueless symbolism, direct or indirect, understood as the Language of Flowers (q.v.), there is an abundant store of traditionary lore associated with all kinds of trees, plants, and flowers. The study of this throws much light on many puzzling survivals in popular folklore, and Mannhardt (1831–80) and Mr J. G. Frazer have shown its importance for part of the problem of primitive religion. It is not infrequent among Australians and Red Indians to find the Totem (q.v.) taking the form of a plant or tree, and for these the individual shows his reverence by refusing to gather or destroy them. We find the worship of trees widely prevalent among savages everywhere, and we have ample evidence that it was an important element in the religion of all the families of the Aryan stock. Grimm thinks the oldest sanctuaries of the Germans were natural woods, and hints at a historical connection between the ancient sacred inviolate wood and the later royal forest—a ludicrous descent from the god to the game-preserver. The oak-worship of the ancient Druids, the sacred fig-tree of Romulus in the centre of Rome, the *Ficus religiosa* of India, and the sacred groves of the Semitic and pre-Semitic races still surviving at Carthage a century after Augustine are ready examples of tree-worship from sufficiently wide centres of civilisation. The primitive mind of the savage readily conceives of a tree as animated by a conscious soul cognate with his own, and he may regard the tree either as its permanent outward organism or merely its characteristic dwelling-place. Hence trees have their place in the doctrine of fetichism, of idolatry, and the upward development of religion. Buddhists do not include trees among sentient beings possessing mind, but recognise the existence of the genius of the tree, and Buddha himself was such as often as forty-three times during his transmigrations. The reverence paid to the famous Bo-tree (q.v.) shows how fundamental a fact is tree-worship, which undoubtedly formed a large part of the old indigenous religion amalgamated by the new philosophical faith. But none the less are the sacred tree and grove to be found within the range of Semitic and Aryan influences, and the obstinate revival, even under the shadow of purer rites, of the Canaanitish Ashera worship proves how deeply they were rooted in the old religion of the land. From all sides we find evidence at once of the great antiquity and uniformity of the worship of trees, whether for the services they render to man, for their venerable antiquity, their form, for particular qualities ascribed to them as containing the seeds of fire, for their situation, as on sombre and lonely mountain-tops, or for their association with certain phenomena, as plagues and pestilences, or certain events in the history of the homestead. In the growth, life, decay, and death of the plant the primitive man easily sees an analogue to his own life-history, and herein we may find the philosophy of the widespread rustic rites associated with marriage and with the birth of children. The custom of scattering flowers and the fruits of the field over the footsteps of a newly-married pair conveys an obvious reference to the belief in the reproductive powers of vegetation and to the fundamental postulate of all sympathetic magic that any effect may be produced by imitating it. Primitive ideas of the fertilising and fruit-bearing powers of nature led easily, according to Mannhardt, to the belief that each tree or plant possesses spiritual as well as physical life, being tenanted either by semi-divine spirits or by the ghosts of the dead; and a natural generalisation of this notion made plants and trees collectively the abode of particular inhabitants—an example of animism developing into polytheism. A forest-god has been deduced from a mere tree-soul, both alike regarded as powerful to produce rain or sunshine, to cause fruits to spring and cattle to easily bring forth their young. A still higher generalisation gave a belief in a genius of plant-life or forest-life, or, higher still, a genius of growth or fertility in general. This universal genius of growth was symbolised by a bush or tree, brought in triumph from the forest, gaily decked, and solemnly planted near the homestead or in the village. We have thus seen both the spirit incorporate in the tree, suffering and dying with it, and the tree considered as the mere dwelling-place of the god; but still further in many cases we find the tree-spirit regarded as detached from the tree, and, through a confusion of his vegetable and anthropomorphic representations, clothed in human form as a man or a girl decked with flowers—the May King, Queen of the May, the Old Woman or Corn-mother of German harvest-fields, the Jack in the Green of young London sweeps, and the like. The existence of those Corn-spirits which especially haunted and protected the waving corn we see dimly recognised in characteristic ceremonies of an English harvest-home, and in the German custom of leaving the

last sheaf of rye in the field as a tribute to the Roggenwulf. The French and German custom of the Harvest May, in which a branch or tree decked with ears of corn is carried home in the last wagon from the harvest-field and hung on the roof of the farmhouse till next year, is closely cognate with the *eiresione* of ancient Greece, and suggests a parallel with some of our own old harvest customs.

Sympathetic affinities between plant and animal life strongly impress the primitive imagination; we find them playing an important part in many cosmogonies, as in the Iranian account of how the first human pair grew up as a single tree, the fingers or twigs of each one folded over the other's ears, till the time came when they were separated, and infused by Ahuramazda with distinct human souls. Other mythical cosmogonic trees that need only be named are the heavenly fig-tree of the Vedas, and the ash-tree Yggdrasil of Norse mythology. In some places trees are informed when their owner dies, and an apology formally made to them by the woodcutter before he fells them; and every one is familiar with the custom of planting a tree at the birth of a child, and the notion of a sympathetic relation subsisting throughout life betwixt the two. The trees planted by Queen Victoria on her visit to an English town, and the Trees of Liberty planted to mark a new political régime, convey unconsciously a survival of the same sympathetic symbolism. The belief that a child's rickets can be cured by passing him through a cleft ash-tree still lingers obstinately in corners of England, and stories of trees giving forth human groans and exuding human blood are common in folk-tales everywhere. Even so late as 1870, in Oxfordshire, a gypsy woman told how Fair Rosamond was changed into a 'Holy Briar,' which bleeds if one plucks a twig. Families, as well as individuals, have tutelary or guardian trees, and Hytén-Cavallius, for example, tells us that the three families of Linnæus (or Linné), Lindelius, and Tiliander were all called after the same tree, an ancient linden or lime which grew at Jonsboda Lindergord. When the Lindelius family died out one of the old lime's chief boughs withered; after the death of the daughter of the great Linnæus the second main bough fittingly bore leaves no more; and when the last of the Tiliander family expired the tree's active life came to an end, though the dead trunk still exists and is highly honoured.

We see then how natural is the notion of symbolising the genius of vegetation under the form of a tree, and thus, as has been shown, we find some hint at the real philosophy underlying the joyous old-world May-day usages, the Maypole decked with streamers, round which young men and maidens danced in chorus, and not less the high ceremonies attending the harvest-home. Even our Christmas-tree, which originally made its way into England and France principally through the influence of Prince Albert and the Duchess Helen of Orleans, is really nothing but a survival of an ancient German custom of heathen origin, and we may safely disregard the foolish theory of its being Christian because the 24th of December chances to be consecrated to Adam and Eve. One legend relates how Adam brought from Paradise a fruit or slip from the Tree of Knowledge, from which sprang the tree from which the Cross was made—an example of a process of myth-making after the fact to which we owe not a few beliefs and customs not understood. But many plants have received a kind of religious consecration from the name of some saint whose festival fell on the day on which they were gathered. And Christianity, like Buddhism, early showed a marvellous adaptability in the way in which it adopted popular rites of an earlier religion, and subtly rebaptised them as its own. Many remnants of primitive superstitions survive in the local English names of plants and flowers, chiefly in connection with the fairies, the devil, the Virgin, and the Cross, and we have a great wealth of association from one cause or other between saints and flowers, as St Agnes with the Christmas rose, St Joseph of Arimathea with the Glastonbury thorn, St Patrick with the shamrock, the Virgin with the white lily, just as Thor had his oak-tree, Venus her myrtle, the Indians the lotus, and the Druids the mistletoe. Again, historical personages and families are frequently associated with particular flowers—it is enough merely to name the orange-lily, the red and white roses, the fleur-de-lis, the *planta genista*, and the violet. Family and clan crests frequently take this form, as the fir, holly, juniper; also national badges, as the rose, thistle, shamrock. More curious and interesting, although obscure, are the notions of magical properties connected as persistently with some plants as medicinal properties are with others. Most prominent in European folklore are the elder, the thorn, and the rowan or mountain-ash; but strange properties are still ascribed to the rosemary, vervain, St John's wort, mandrake, asphodel, and to fern-seed; and many flowers lend themselves through some obscure inherent fitness to special methods of divination. The doctrine of Signatures (q.v.), of such importance in the history of medicine, opens up a special chapter of sympathetic magic, involving the belief that plants bore by nature marks indicating plainly for what diseases they were medicinally useful. The trees of Paradise, of Chaldæan and other cosmogonies, the oracular oaks of Dodona, those trees of healing spiritually allegorised in the Apocalypse, the trees of Liberty of the French Revolution, and the trees round which an Indian bride and bridegroom walk hand in hand, point as unmistakably to a real sympathetic affinity between the human and the vegetable world as did the Dryads, Fauns, and Satyrs of the ancient Hellenic mythology, with their analogues our own elves and fairies of the woods, the transformation-myths, the Orpheus whose lyre laid its charm on beasts and trees alike, or the Pan at the report of whose death all nature mourned aloud.

See W. Mannhardt, *Roggenwulf und Roggenhund* (Danzig, 1865), *Die Korndämonen* (Berl. 1868), *Der Baumkultus der Germanen und ihrer Nachbarstämme* (Berl. 1875), *Antike Wald- und Feldkulte* (Berl. 1877), and the posthumous *Mythologische Forschungen* (Strassb. 1884); A. de Gubernatis, *La Mythologie des Plantes* (2 vols. Paris, 1878–82); M. von Strantz, *Die Blumen in Sage und Geschichte* (Berl. 1875); H. Pfannenschmid, *Germanische Erntefeste im heidn. u. Christl. Cultus* (Hanover, 1878); Rev. Hilderic Friend, *Flowers and Flower-lore* (1884); V. Jahn, *Die Deutschen Opfergebräuche bei Ackerbau und Viehzucht* (Breslau, 1884); and J. G. Frazer, *The Golden Bough* (2 vols. 1890). The last work contains a distinct contribution of the greatest value to a scientific knowledge of the worship of vegetation, but it seems probable that a serviceable enough theory has been carried too far, and at any rate many of its conclusions remain to be tested by the fresh generalisations of a later day. Its starting-point is the mysterious story of the Arician lake, well known through Turner's picture and the allusion in Macaulay's *Lay of the Battle of Lake Regillus*. The lake occupies the site of the ancient sanctuary of Diana Nemorensis. In its grove grew a sacred tree, from which whoever succeeded in breaking off 'the Golden Bough' had the right to challenge the priest of the sanctuary to single combat, and, if victorious, to reign in his stead. Mr Frazer sees here a survival of ancient tree-worship, the priest being an incarnation of the spirit of the tree, which passed continuously on his being killed into a new and more vigorous incarnation. He finds it also an evidence of

primitive human sacrifice, and identifies the Golden Bough with the mistletoe growing on the oak—the only thing in nature which could bring Balder to his doom. He has with unequalled learning and ingenuity traced many cognate customs in classical antiquity, as well as parallels in our modern rustic spring and midsummer customs, and finds the same significance of the death and resurrection of vegetation under the various forms of the Greek myth of Demeter and Persephone, the Syrian Astarte and Adonis, the Phrygian Cybele and Attis, the Egyptian Isis and Osiris.

Planudes. Maximus. See Anthology.

Planula. See Hydrozoa.

Plasencia, a decayed town of Spain, in Estremadura, 130 miles W. by S. of Madrid and 43 NE. of Caceres, is surrounded with double walls (1197), has a fine Gothic cathedral (1498), and a pop. of 7090. The monastery of San Yuste, to which Charles V. retired after his abdication, lies 24 miles to the east of Plasencia.

Plasma, a rare siliceous mineral, a variety of quartz or chalcedony, of a dark-green colour, black when unpolished and seen by reflected light, but very translucent when held between the eye and the light. It is very nearly allied to heliotrope or bloodstone, but has no red spots, is more translucent, and is not susceptible of so brilliant a polish. The name is also used in biology for the simplest form of organised matter in vegetable and animal bodies, out of which the tissues are formed, especially of the blood-plasma. See Blood.

Plasmodia. See Cell, Myxomycetes.

Plassey (*Palási*), a battlefield on the Bhágirathi River, 96 miles N. of Calcutta. The river has now eaten away the scene of the struggle. Plassey is celebrated in the history of India for the great victory gained by Clive over Suraj ud Dowlah, subahdar of Bengal, 23d June 1757, a victory which really laid the foundation of British supremacy in India. See Clive.

Plaster. See Cast, Gypsum, Building.

Plastering, the art of covering the internal faces of walls, the partitions, and the ceilings of a house or other building with plaster. It is difficult to get plaster to keep completely dry on the inside faces of external walls unless they are first covered with lathing (narrow strips of wood, see Lath). Ceilings and wooden partitions are always lathed so as to hold or key the plaster. Plastering is sometimes done in two, but most usually in three coats. The first or foundation coat is formed of lime and sand (mortar) mixed with hair. This is called *pricking* if done upon lath, and *rendering* if it is spread on a bare brick or stone wall. It is crossed with deep incised lines to key the second coat, which consists of fine lime mixed with some coarse plaster of Paris (see Gypsum) *floated* on. The first coat should be completely dry before the second is added, but the latter is generally still a little damp when the third coat or *set* is put on. This last coat is usually composed of a mixture of fine lime, plaster of Paris, and a little size, and is worked so as to produce a very smooth surface. The implements used by the plasterer are chiefly trowels and floating tools, with running moulds for mouldings. Ceiling ornaments and other enrichments are formed of plaster of Paris cast in moulds. Mouldings are run in the same material.

Plaster of Paris. See Gypsum.

Plasters are a class of medicinal agents consisting of 'adhesive substances, spread upon leather or cloth, so as to stick to the part of the body to which they are applied.' The plasters of the British Pharmacopœia owe their adhesiveness either to a combination of oxide of lead with fatty acids, or to the presence of a tenacious resin, or to both. The most important are lead plaster, or diachylon, which enters into the composition of many of the others; resin and pitch plasters; belladonna and opium plasters; mercury and ammoniacum and mercury plasters; and cantharides or blistering plaster. Some of the most tenaciously adhesive of plasters (not in the Pharmacopœia) are made with preparations of india-rubber. Court or sticking plaster, for dressing slight wounds, consists of a thin layer of isinglass spread upon silk, and differs from the others mentioned in requiring to be softened with warm water before it will adhere; Goldbeater's Skin (q.v.) is also used for the same purpose. They are employed with two distinct aims—viz. to act *mechanically*, as by affording artificial support to weak muscular structures, by preventing threatened or tedious excoriations, by protecting parts already excoriated from the action of the air, &c.; and to act *medicinally* as counter-irritant, stimulant, discutient, alterative, anodyne, &c.

Plastilina. See Clay.

Plata, La. See Argentine Republic, La Plata, La Plata (Rio de).

Platæa (Gr. *Plataiai*), a city in the western part of Bœotia, on the borders of Attica, and at the foot of Mount Cithæron, 6 miles from Thebes. In 480 B.C. it was destroyed by the Persians, because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year it was the scene of the glorious victory won by the Lacedæmonian Greeks, under Pausanias and Aristides, over the Persian hordes commanded by Mardonius. In the third year of the Peloponnesian war (429) it was attacked by a Theban-Lacedæmonian force, and heroically defended itself for more than two years, until it was starved into surrender; the little garrison of about 200 men were put to the sword, and the city was razed to the ground. Such of the Platæans as escaped were hospitably received at Athens. By the treaty of Antalcidas (387) their children were allowed to go back again, and rebuild their city, after an exile of forty years; but they were again driven out by their implacable enemies the Thebans; and half a century elapsed before the victory of Philip of Macedon at Chæronea enabled the Platæans to finally return to their homes. After this the city was inhabited till the 6th century A.D.

Plateaus. See Tablelands.

Plate-marks. See Hall-marks.

Plate-powder, a composition of Rouge (q.v.) and prepared chalk used for cleaning gold and silver plate and plated articles. A gray plate-powder is also sometimes made by levigating quicksilver with twelve times its weight of prepared chalk; it puts a remarkable brilliancy on silver-plate, but is very injurious to it.

Plating signifies the covering of an inferior metal with one of the precious metals, the object being to give the appearance of silver or gold to articles chiefly intended for table use. Previous to the introduction of electro-plating (see Electro-metallurgy) the method generally pursued was *Sheffield-plating*—by means of a plating furnace—soldering on to one or both sides of an ingot of the baser metal a thin plate of silver. See also Tin-plate, Galvanised Iron.

Platinotype. See Photography.

Platinum (sym. Pt; atom. wt. 197·4; sp. gr. 21·48 to 21·50) is one of the 'noble metals.' It is found only in the native state, usually occurring in small glistening granules of a steel-gray colour, which always contain, along with some gold, copper, iron, and sand, an admixture, in varying proportions, of several metals—iridium, rhodium, palladium, osmium, ruthenium—most of which are rarely found

except in association with platinum. Sometimes, however, it is found in masses of the size of a pigeon's egg, and pieces weighing ten or even twenty pounds have occasionally been found. It was originally found in the Spanish gold-mines of Darien, but is now chiefly obtained from the Ural Mountains, though it has also been found in Brazil, Colombia, San Domingo, California, Oregon, Canada, and Borneo.

There are two modes of obtaining platinum in the form of ingots from the crude native metal, both of which require notice. The earlier method—Cocks's, usually attributed to Wollaston (*c.* 1800–28)—was to precipitate a solution in *aqua regia* by a solution of sal ammoniac; the precipitate on incineration gave spongy platinum, which was pressed into form and hammered hot, so as to form an ingot, which it happens to be able to do, since platinum welds like wrought-iron when not too highly polished.

Deville and Debray's method is first to form a fusible alloy of this metal with lead, by exposing the platinum ore—2 cwt. being used in a single experiment, with equal weights of galena and litharge gradually added, and a little glass to act as a flux—to full redness in a reverberatory furnace lined with clay. The sulphur of the galena is oxidised and expelled, and the liquid alloy of lead and platinum is allowed to rest for some time, to allow the osmide of iridium, which is not affected by the preceding operations, to sink to the bottom. The upper portions of the alloy are then decanted, and cast into ingot-moulds, which are submitted to cupellation: and the metallic platinum which is left after the cupellation is melted and refined in a furnace of lime—which is employed in consequence of its being a very bad conductor of heat—by means of the oxyhydrogen blowpipe. The platinum obtained in this manner is nearly pure, and very ductile and malleable.

Platinum exhibits a bluish-white metallic lustre; it is exceedingly malleable and ductile, and is very infusible, melting only before the oxyhydrogen blowpipe, or in a very powerful blast-furnace, such as that used by Deville and Debray (fusing-point, 1779° C.). It expands less by heat than any other metal, and it is the heaviest form of matter known, with the exception of iridium (sp. gr. = 22·42) and osmium (22·48). It is unaffected by atmospheric action, and does not undergo oxidation in the air at even the highest temperatures. It is not acted on by nitric, hydrochloric, sulphuric, or hydrofluoric acid, or, in short, by any single acid; but in aqua regia it slowly dissolves, and forms a soluble tetrachloride. In consequence of its power of resisting the action of acids it is of great service in experimental and manufacturing chemical processes, platinum spatulas, capsules, crucibles, &c. being employed in every laboratory. Platinum is, however, corroded if heated with the alkalies or alkaline earths, and especially with a mixture of nitrate of potash and hydrated potash, an oxide being formed which combines with the alkaline bases. In consequence of its infusibility and its non-oxidisability by atmospheric action, it is in great demand for electrical as well as for chemical apparatus; and the recent introduction of platinotype processes in Photography (q.v.) has caused such a run upon platinum that its price has gone up from about 35s. per oz. in 1880 to 55s. in 1889, and 80s. in 1890.

The form of the metal known as *spongy platinum* has been already noticed. The metal may, however, be obtained in a state of subdivision much finer than that in which it is left on heating the double chloride of platinum and ammonium—viz. in the state known as *Platinum Black*. In this form it resembles soot. It may be prepared in various ways, of which one of the simplest is to boil a solution of bichloride of platinum, to which an excess of carbonate of soda and a quantity of sugar have been added, until the precipitate formed after a little time becomes perfectly black, and the supernatant liquid colourless. The black powder is then collected on a filter, washed, and dried by a gentle heat. In its finely comminuted state, either as spongy platinum or platinum black, it possesses a remarkable power of condensing and absorbing gases, one volume of platinum black being able to absorb more than 100 volumes of oxygen. This absorption appears to be accompanied by a conversion of some or all of the oxygen into the modification known as Ozone (q.v.), since the metal becomes capable of exerting the most energetic oxidising action, even at ordinary temperatures. For example, it can kindle a jet of hydrogen, can oxidise sulphurous acid into sulphuric acid, ammonia into nitric acid, and alcohol into acetic acid, the rise of temperature in the last case being often sufficiently great to cause inflammation. Platinum in the compact form, as foil or wire, possesses similar powers, but in a far lower degree.

Platinum may be easily alloyed with most of the metals, the alloys being in general much more fusible than pure platinum. Hence care must be taken not to heat the oxides of metals of easy reduction, such as lead and bismuth, in platinum crucibles, as, if any reduction took place, the crucible would be destroyed by the fusion of the resulting alloy. An alloy of platinum, iridium, and rhodium is found, by the investigations of Deville and Debray, to be harder and capable of resisting a higher temperature than the pure metal, and hence is admirably adapted for the formation of crucibles, &c.; but it is not now in the market.

There are two *oxides* of platinum, a protoxide, PtO, and a binoxide, PtO_2. The *sulphides* and *chlorides* correspond in number and composition to the oxides. Of these compounds the tetrachloride, $PtCl_4$, alone requires notice. It is formed by dissolving platinum in aqua regia, and evaporating the solution to dryness; and it is obtained as a deliquescent, reddish-brown mass, which forms an orange-coloured solution in water, from which, on evaporation, it crystallises in prisms. It is also freely soluble in alcohol and ether. A solution of this salt is much used for the recognition and determination of potash and ammonia.

Plato, the great Athenian philosopher, was born during the early years of the Peloponnesian war, most probably in 427 B.C. Diogenes Laertius (q.v.), in his gossiping *Lives of the Philosophers*, and other writers of the Christian era have handed down a considerable amount of detail respecting his life, but most of it is of very doubtful value. As time went on, legends gathered round a famous name; and many of the authorities used by Diogenes were in all probability, like Diogenes himself, almost entirely wanting in critical capacity. According to one account Plato was born in Athens itself, according to another in the island of Ægina. He came of an aristocratic family, his father Ariston boasting descent from Codrus the last king of Athens, who was said to be descended from the god Poseidon; whilst the family of his mother, Perictione, claimed kinship with Solon, and through Solon with Neleus, a son of Poseidon. Even this double claim to superhuman ancestry was not sufficient for the admirers of the 'divine' Plato. Diogenes tells us on the alleged authority of (among others) Speusippus, Plato's own nephew and successor in the academy, that the story was current at Athens that his real father was Apollo, and that the god appeared in a vision to Ariston, who thereupon kept away from his wife till her child was born. Plato's

birthday was celebrated on the same day (at the end of May) as that of Apollo himself. Bees from Hymettus are said to have fed the infant with their honey. Plato was originally named after his grandfather, Aristocles; but his gymnastic teacher is said to have called him 'Platōn,' because of his broad shoulders, though others say he got this name from the breadth of his forehead. There is a story that he wrestled at the Isthmian games. He cannot well have escaped military service during the terrible struggle of Athens in the last years of the Peloponnesian war. In youth he is said to have written poetry, and this we can easily believe: a few epigrams in the 'Anthology' are ascribed to him. With regard to his philosophical education we have the important testimony of Aristotle (*Metaph.* i. 6), that from his youth he had been familiar with Cratylus, a follower of Heraclitus, and that the other philosophic influences under which he came were those of Socrates and of the 'Italic' schools—i.e. Pythagoreans and Eleatics. Critias (afterwards one of the 'Thirty Tyrants') and Charmides were both maternal relatives of Plato, and both belonged to the Socratic circle. Possibly it was through them that Plato came under the decisive influence of Socrates. If Plato was, as Diogenes says, twenty years old when he first became companion of Socrates, his discipleship lasted for eight years. According to his own account in the *Phædo*, Plato was prevented by illness from being present at the last conversation and death of his master (399 B.C.).

Plato made no attempt to enter on a political career. Through family ties he was connected with the anti-democratic party, who admired Sparta. His youth was passed amid the disasters and failures of the Athenian democracy; and the martyrdom of the teacher who had inspired him would not tend to increase his sympathy with that form of government. After the death of Socrates he seems to have stayed some time at Megara, where Euclides, who had been one of the Socratic circle but belonged also to the Eleatic school, had established himself. Euclides developed the Eleatic philosophy in the direction which Zeno ('the father of logic') had begun—he was chiefly occupied with what, after Aristotle's time, came to be considered logical questions. His school was known as the 'Dialectical' or 'Eristic'—i.e. 'disputatious.' This sojourn at Megara was doubtless an important stage in the development of Plato's thought. How long he stayed at Megara we do not know; nor can we tell with certainty whether he was back at Athens in 394 (he is said to have taken part in a Corinthian campaign), or whether he did not return to Athens till ten or twelve years after the death of Socrates. During this period of his life he is said to have undertaken extensive travels—to have visited Cyrene, Egypt, Italy, and Sicily. The visit to Sicily is almost certain; visits to the Magi and the Persians, the Babylonians, and the Hebrews are undoubtedly fictions of a later age, which supposed that wisdom could only come out of the East. The despotism of the elder Dionysius in Syracuse probably helped to suggest the pictures of the tyrant in the *Republic* and *Gorgias*. On his way back from Sicily Plato is said to have been seized by order of Dionysius and sold as a slave in Ægina, but to have been ransomed by a certain Anniceris of Cyrene. The return to Athens has been variously assigned to the years 389 and 387. Plato now began to teach in the Academy (q.v.), a place of exercise in the western suburb of Athens, planted like a grove, and named from the hero Acadēmus. There and in his own garden, which was adjacent, he gathered round him a band of disciples, teaching them probably, like his master Socrates, mainly by conversations, and embodying the results of his thinking and teaching in his written *Dialogues*. Two more visits to Sicily interrupted the quiet of these later years. Soon after the death of the elder Dionysius (368) his friend Dion summoned him to come to Syracuse, in the hope that he might convert the younger Dionysius to philosophy, and so realise the dream of a philosopher-king. The young despot welcomed him warmly, but soon became weary of serious discussions, quarrelled with Dion, and banished him; and Plato had to give up his fruitless task. A third journey to Sicily (about 361) was undertaken in the vain attempt to reconcile Dionysius to Dion. Plato's own life, it is said, was only saved from the tyrant by the intercession of the Pythagorean Archytas. On his return to Athens (360) he again resumed his teaching and writing, till, after a peaceful old age, he died 'in his eighty-first year' at a wedding-feast (347). He was succeeded in the Academy by his sister's son, Speusippus; but his greatest disciple was Aristotle, who must have come under his influence after the return from the second Sicilian voyage.

Of Plato's philosophical writings none apparently have been lost; but along with undoubtedly genuine works there have come down to us others whose authenticity is open to question. Thrasyllus, a scholar of the time of Augustus and Tiberius, considered thirty-six of the works ascribed to Plato to be genuine, rejecting a few quite unimportant writings as spurious. This 'canon of Thrasyllus' probably represents the tradition of the Alexandrian library. Aristophanes, one of the Alexandrian librarians (about 264 B.C.), had arranged several of Plato's dialogues in 'trilogies' (groups of three), following the analogy of Attic dramas. Plato himself suggests at least two such trilogies—viz. *Republic*, *Timæus*, *Critias* (unfinished); *Sophist*, *Statesman*, *Philosopher* (never written). Thrasyllus adopted an arrangement in tetralogies, making nine groups of four, only one of which groups (viz. *Euthyphro*, *Apology*, *Crito*, *Phædo*, which give a connected picture of the trial, last days, and death of Socrates) is anything but extremely artificial. Grote accepts all the works in the 'canon of Thrasyllus,' believing that the Alexandrian library had every means of obtaining a genuine collection of Plato's writings from his successors in the Academy; but almost all other modern scholars reject the *Epistles*, some of which may, however, be very early forgeries. And the authenticity of some ten or more of the dialogues has been very much disputed. Fortunately, the more important works are the least open to question. We have Aristotle's statement that the *Laws* were written by Plato after the *Republic*. Beyond that we can only conjecture the order in which the dialogues were written; and the hypotheses of different scholars have varied greatly. We may safely put aside the theory of Schleiermacher (with whom the modern critical study of Plato begins), that Plato quite early in life had formed a complete system of philosophy in his mind, and that the dialogues were published by him in an order intended to unfold this system gradually to the world. It would be more true to say that Plato never had any completely formed system, and during a long life of speculation his opinions must have undergone modification. We cannot, indeed, with complete certainty arrange his dialogues in a series representing exactly his mental development (as K. F. Hermann and others have attempted); but the student may most profitably consider them in groups, suggested by the different influences that acted on him, and especially by his changing attitude towards the teaching of Socrates. First of all would come those short dialogues in which, so far as we can judge by comparing him with

Xenophon, Plato does not go beyond what the actual Socrates might have said. Such are the dialogues which deal with some particular virtue; thus, in the *Charmides* Socrates questions the beautiful and modest youth Charmides as to what the virtue of modesty or 'temperance' is. In the *Laches* he questions the soldier Laches about courage. The most important of this group is the *Protagoras*, in which Socrates argues against this famous sophist that all virtue is one, and that it is identical with knowledge. Some of these slighter dialogues may have been composed before the death of Socrates; Diogenes Laertius tells us that Socrates on hearing Plato read the *Lysis* (which deals with friendship) said: 'O Hercules! what a lot of lies the young fellow has told about me.' Ancient tradition made the *Phædrus* the earliest dialogue; but this almost certainly belongs to a later period, though earlier than the *Republic*. The *Apology*, or 'Defence of Socrates on his Trial,' has probably more historical accuracy than any other composition of Plato's (Plato tells us he was present at the trial), and may have been written soon after the death of Socrates. The *Euthyphro* (concerning piety) and the *Crito* (Socrates in prison) may belong to the same period. The *Phædo*, however (the last conversation of Socrates, on the immortality of the soul), is probably of later date, as it implies the theory of ideas, and may be assigned to a time after Plato's visit to Sicily—i.e. after he had come more strongly under Pythagorean influences. Some modern scholars, laying great stress on the 'Megaric' influence, assign the great metaphysical dialogues (*Parmenides*, *Theætetus*, *Sophist*, *Statesman*) to the time between 399 and 386, when Plato began his teaching at the Academy. Others, with more probability, consider these dialogues and the *Philebus* to belong to a later period than the *Republic*, and this opinion is gaining ground. The *Phædrus*, *Symposium* ('Banquet'), *Gorgias*, *Republic*, *Phædo*, in which (along with the *Theætetus*) Plato's literary skill is at its very highest, may perhaps be all assigned to the period of his life after forty, but before his old age. In these dialogues the personal characteristics ascribed to Socrates are probably represented with historical and, at least, with dramatic truth; but theories are introduced which betray strong Pythagorean influences. We must of course remember that while Plato idealises Socrates, and makes him more of a metaphysician than in all probability he was, Xenophon, who has a very unphilosophical mind, most certainly understates him, and makes him more of a commonplace moralist than he must have been in order to stimulate Greek thought as he did. In the *Timæus* Plato would have felt it inappropriate to make Socrates the exponent of theories about the physical universe, and after a short introductory conversation the dialogue form is deserted, and Timæus, a Pythagorean, expounds the cosmogony of his school. In the *Sophist* and *Statesman* 'an Eleatic stranger' is the chief speaker; in the *Parmenides* the youthful Socrates is criticised by the great Eleatic philosopher. In the *Laws* Socrates does not appear at all, the leading speaker being 'an Athenian stranger' (Plato himself?). May we not regard this as an indication that in his later years Plato felt himself farther away from his master? These later dialogues, in fact, seem like a transition from the Plato of the *Phædrus* and of the *Republic* to Aristotle.

It is customary to treat of Plato's philosophy under the three heads of dialectic (or logic), physics, and ethics. But, it must be remembered, these divisions did not exist for Plato himself, nor, in fact, had he, strictly speaking, a 'system' of philosophy. Plato's philosophy may most correctly be regarded as a development of the teaching of Socrates, but containing elements derived from the earlier philosophies from which Socrates had purposely turned away. Aristotle's philosophy is, however, a development of Plato's; and we, knowing what becomes of Plato's suggestions in the hands of his pupil, are able and apt to see a greater amount of system than Plato himself would have recognised.

The dialogue was to Plato much more than a mere literary form into which he chose to fit his thoughts. The 'conversations of Socrates' gave to Plato his conception of the method of philosophy. 'Dialectic' comes from a word which means 'to converse,' 'to discuss;' and it is significant that Athenian philosophy originated not in the meditations of the solitary recluse, but in the discussions of a city of talkers. It is said that Zeno the Eleatic used the dialogue for philosophical writing before Plato, but this is very doubtful. In many of the later dialogues the chief speaker has so much of the talking to himself that the dialogue becomes a rather empty form, and is evidently yielding place to the lecture as the vehicle of philosophical exposition.

According to a well-known sentence of Aristotle, the germs of logical doctrine which may be ascribed to Socrates are 'the inductive method' and the endeavour to get 'general definitions.' When people spoke about persons or acts as just or beautiful, Socrates would insist on asking 'What is justice?' 'What is beauty?' and would test every definition brought forward by applying it to particular instances, content to remove error even where complete truth could not be obtained. This is the procedure of Plato in the earlier dialogues. In the *Theætetus*, however, the Platonic Socrates asks the profounder question, 'What is knowledge?'—i.e. true or scientific knowledge. It is not 'sensation' (or 'perception'), as Protagoras and his followers suggest: sensation alone gives us no objective certainty, valid for every one. Nor is it 'opinion.' Opinion may be true, but has no certainty. A man only 'knows' when he has got at the reasons or causes of things, when he sees facts not in an isolated way, but connected by the 'chain of causation' (*Meno*): he must be dealing with what is permanent and universal. What then is this? Plato's answer comes to be found in the theory of 'Ideas.' (The word means properly 'forms' or 'shapes,' and so 'kinds.' The analogy of sculpture may help one to understand how the Greeks came to regard 'the form,' in contrast to the 'material,' as the essential element.) This theory, following Aristotle's guidance, we may consider a development of the Socratic 'universal conception,' and also of the Pythagorean doctrine of 'numbers.' By this theory Plato seeks to reconcile the opposing views of the Heracliteans and of the Eleatics (q.v.). According to Plato, both the one, the permanent, and the manifold, the changing, have their place in the universe, the former in the world of ideas, the intelligible world, with which 'science' deals, the latter in the world of sense, with which mere 'opinion' is content. In the *Republic* Plato elaborates this theory of knowledge, and gives a symbolical representation of it in the famous image or 'myth' of 'the Cave.' The majority of mankind are pictured by him as prisoners in a subterranean cavern, chained with their backs to a fire, looking at the shadows thrown by it on the rocky wall and mistaking them for realities. The turning round of some of these prisoners to the light, and the toilsome ascent up the steep slope to the mouth of the cave, and the gradual training of their eyes bewildered in the sunlight to see the real things in the upper world, and finally to look

up to the sun itself—this represents the education of the philosopher. Education is 'a turning round of the eye of the soul.' Learning, according to the more startling language of the *Meno* and *Phædrus*, is 'recollecting:' the soul in a previous existence has beheld the 'ideas,' and knowledge is possible just because the mind does not acquire something alien to it, but recovers what is its own. The way from the life of the senses and of mere vague opinion to the highest or philosophical knowledge is through the mathematical sciences. Mathematics, being the only science which had then outgrown the merest infancy, is to the Greeks the type of science in general. (Plato is said to have had the words 'Let no one ignorant of geometry enter' inscribed on the door of his school.) In the conceptions of mathematics we have a clue to the understanding of Plato's theory of ideas. The geometrician looks at a particular triangle, but he speaks not of *this*, but of *the* triangle. The triangles we see are triangles only by 'participating in' ('imitating,' the Pythagoreans would have said) *the* triangle. And it remains true for us still that we can only scientifically know anything in so far as we can find in it a universal element, which manifests itself or 'is present' (in Platonic language) in the particular. The botanist, for example, knows a particular plant only as a specimen of a *species* (the Latin equivalent of Plato's 'idea'). But the philosopher must not remain in the region of the various special sciences: he has the passion for unity and universality. Plato has a vision of the true science which is above all particular sciences, and is the unity and 'coping-stone' of them all: and this he calls in a special sense 'dialectic,' which does not like mathematical thinking need the help of sensible images, but deals with 'ideas' alone in their relation to one another and to the highest of all, 'the idea of the good.' These ideas are not mere concepts of our minds: they are, in Plato's phrase, 'the most real existences.' The extreme form of mediæval 'Realism,' according to which universals are prior to and more real than particular things, is a crude version of Plato's doctrine. It is indeed an adaptation of Platonic philosophy to Christian theology, for which Plato gives no sanction, if the ideas are called 'the thoughts of God;' but the phrase is perhaps less misleading than many others which have been used about them. Plato does speak (in *Republic*, x.) of God having 'made' the ideas, as a human artificer makes things in imitation of them; but he is there talking in pictorial language. God in Plato's system is rather the 'idea of the good,' the good-in-itself, which is the cause alike of knowing and of being, as the sun in the visible world is the cause both of light and of life. In the *Timæus* the world is said to be fashioned by the Creator or Artificer after the pattern of the ideas; but here also the language is figurative. Plato's 'ideas' must, however, be thought of both as 'real kinds' and as archetypes. Plato's presentation of his theory varies: most probably the theory itself underwent modification. In the *Parmenides* some of the objections made to it are the same as were afterwards urged by Aristotle—a remarkable instance of a philosopher criticising himself.

The relation of the hierarchy of the ideas to the supreme idea of the good is nowhere worked out by Plato. Dialectic remains only an ideal science. The true dialectician is he who will see things in their unity (compare Mr Herbert Spencer's definition of philosophy as 'completely unified knowledge'): he will also 'divide things rightly according to their kinds.' The method of philosophy is a bringing together and a dividing (*synagōgē* and *diairesis*). In this we may recognise the germ of Aristotle's 'induction and deduction.'

The *Timæus* is the one work which Plato has devoted to the philosophy of nature; and though it has exercised directly and indirectly an enormous influence over the ancient and mediæval world, as it has specially attracted mystical and theosophical commentators, in Plato's own view it occupies a very subordinate position. We are again and again warned by him not to expect strict truth, but only approximations and figurative statements ('myths') in dealing with such subjects. The notion of 'emanations,' which plays so great a part in later philosophy is latent in the *Timæus*. The Cosmos, or order of the universe, is the 'one only-begotten' image of God, its father and creator (*Demiourgos*—i.e. 'artificer'). The Creator was good, and wished to make the world as like himself as possible; but no created or visible thing can be perfect. The material out of which the orderly world is made introduces imperfection into it. (This conception of matter as evil had a potent influence in later times, especially when combined with Oriental ideas—e.g. in Gnosticism, q.v.) So, too, the eternal Creator could not make the world eternal like himself, and in making it made Time, 'the moving image of eternity.' To the obscure details of Plato's cosmology and physics it would be unprofitable to refer here. Cosmology is again introduced, but briefly, and with similar warnings that it is to be treated as mythical, in connection with the immortality of the soul in the *Phædo* and *Republic*. The soul of man (like the 'soul of the universe') is intermediate between the ideas and the corporeal. The human soul, as it exists in the body, has three parts or elements: (1) the rational; (2) the spirited element; (3) the appetitive. The rational element alone, which is the soul in its true being as it is apart from mixture with body, is properly immortal. The doctrine of immortality (i.e. the pre-existence of the soul as well as its existence after death) is introduced in the *Phædrus*, *Republic*, and *Phædo*, and is the main subject of the third. In all Plato makes use of the Pythagorean notion of transmigration. What he says must be taken as largely mythical and figurative. His whole philosophical thinking implies the eternity of Reason, but how far he believed in what is now understood by personal immortality has been and may be doubted. Wordsworth's famous *Ode on Immortality* is generally considered 'Platonic;' but it turns on a misapplication of Plato's doctrine of 'recollection.' Plato would certainly not hold that the new-born infant is nearer perfection than the aged philosopher.

Plato is so far true to the example of Socrates that, though he has metaphysical interests which were alien to his master, yet the practical interest always predominates. Philosophy is to him not mere intellectual speculation, but a habit of mind and a manner of living. As we have seen, the highest of the ideas is 'the good.' He cannot accept the Cyrenaic view that pleasure is the good; but neither does he agree with the Cynics that all pleasure is evil. Pleasures are good or bad, high or low, according to the part of the soul to which they belong. Socrates had identified virtue and knowledge, had asserted that virtue was one, and that virtue could be taught. All these doctrines Plato accepted; but modifications gradually appear. In the *Republic*, the dialogue in which all the various elements of his philosophy are united more than in any other, Plato accepts without proof the popular distinction of four 'cardinal virtues' (as they afterwards came to be called), and fits them in with his psychology. Wisdom is the virtue of the reason, Courage of the spirited element, Temperance (i.e. Moderation, Self-control in general) is the virtue of the lower parts in their relation to the higher, while Justice

('Righteousness' would perhaps be a better word) is not the virtue of any special part, but of the whole soul, and is defined as 'every part doing its own work and not interfering with the others.' To arrive at the nature of Justice (the professed object of the discussion) the Platonic Socrates has turned 'from the small to the large letters'—i.e. from the individual to the state, where human nature can be seen 'writ large.' Wisdom is the virtue of the rulers, Courage of the warriors, Temperance or Moderation is the harmony resulting from the obedience of the lower to the higher, and Justice is the virtue of the whole state. A perfect state would require a special ruling caste, and the only true rulers in Plato's opinion are philosophers. Plato allows that there may be ordinary virtues resulting from custom or right opinion (cf. *Meno* and *Phædo*), but the highest type of conduct must be bound up with the highest type of knowledge. Those alone who have the philosophic nature (which is sometimes described by him as the passionate love of truth) are the proper rulers in a perfect state, and in the philosophic nature all virtues are united. In this ideal commonwealth (the parent of so many 'Utopias'), besides the paradox of the philosopher-king, the other paradoxes by which Plato startled his contemporaries were (1) that men and women should have the same education and the same pursuits, and (2) that private property and the family should be abolished. All things were to be in common; and the breeding and rearing of the citizens was to be entirely under the control of the philosopher-rulers. Just as in his theory of knowledge Plato's ideal is unity, so his political ideal is that the state should be as much as possible one, one as a family is one, or rather as one individual is. All are to be 'members of one body.' Some of the features in Plato's ideal state were doubtless suggested to him by the Pythagorean brotherhoods, many of them by the actual institutions of Sparta. In fact, Plato's ideal state might be described as a combination of philosophy with Spartan military discipline. Without the philosophy we have an inferior form—the Spartan state, or 'timocracy,' in which not philosophy but military *honour* is the ruling principle. Inferior to that comes oligarchy, of which the ruling principle is *wealth*. Lower still is democracy, the *equality* of good and bad alike; and worst of all is tyranny, the rule of the 'wild-beast element in man.' In the *Statesman* Plato gives a rather different classification of constitutions, recognising both a better and a worse form of democracy, and placing both below aristocracy, but above oligarchy: in the true state the number of the rulers matters not, if only they have 'the science of ruling.' In the *Laws* he elaborates a second-best state, giving up communism as too difficult of attainment, and proposing a complete equalisation of property. In the *Laws* also he praises 'mixed government.'

In the earlier part of the *Republic* Plato discusses the place of art in education. Homer and Hesiod were the Greek 'Bible;' but Plato objects to much in the poets and in the popular religion as false and immoral. Music and poetry should be simple (here again the complex, the manifold, is of the nature of evil), and should imitate only what is good, hence dramatic art is especially objected to. Towards the end of the dialogue he goes further, and objects to all 'imitation,' whether in painting or in words, as being only a copy of the so-called real things, which are themselves only a copy of the true reality—the ideas: and so he drives the poets from his ideal state. Aristotle's *Poetics* may be regarded as in part a 'Defence of Poesy' against Plato's criticism. Why, it has often been asked, has Plato, himself so great an artist, dealt so Puritanically and so unsympathetically with art? Partly, perhaps, because the first steps in reflection about art, as about religion, imply a certain withdrawal from the sway of that which is to be criticised and understood. But the *Republic* gives only one side of Plato's thought on art. In the *Symposium* (in which the banqueters praise Love in turn) and in the *Phædrus* 'the beautiful' occupies the same place that 'the good' does in the *Republic*. Plato is after all a true Athenian, and thinks of the good under the form of the beautiful. ('Beautiful-and-good' is the Greek equivalent of 'noble' or 'gentleman' in its best sense.) 'All that is good is beautiful,' he says in the *Timæus*. The true lover is akin to the philosopher, and loves the beauty of the soul rather than the beauty of the body, and ascends from the love of the many beautiful to the love of absolute beauty. There is indeed a strain of asceticism in Plato's view of life; but there is none of the Cynic contempt for the beauty of the human form and for the graces of social intercourse. In the *Phædo* Socrates speaks of the body as 'the prison-house of the soul,' and of philosophy as 'the practising of death.' But Socrates at the banquet speaks somewhat differently from Socrates awaiting his end: and in the *Republic* the body has to be carefully trained that it may be a fit servant of the soul, and the young are to grow up amid fair sights and sounds.

Plato's influence on human thought has been even more widely diffused, but is more difficult to measure than that of Aristotle. The various schools of the Old, Middle, and New Academy caught only a small portion of his spirit. The Stoics, especially the later Stoics, borrowed much from him. Perhaps no school of Greek philosophy was unaffected by him. In Alexandria Jewish thinkers fell under his fascination (see PHILO); and Christian theology is largely Platonic. But the Alexandrian Platonists and the Neoplatonists (q.v.) differ from Plato himself in making the *Timæus* the centre of his system. The writings ascribed to Hermes Trismegistus and Dionysius the Areopagite belong to the Neoplatonic period. The latter was translated by Erigena in the 9th century, and Platonism reached the western world in the middle ages through the medium of those mystical writers. The Italian Renaissance and the revolt against Scholastic Aristotelianism revived the study of Plato's own writings; but the enthusiasm for Plato in the 15th century at Florence and the less important 'Cambridge Platonism' of the 17th century were both after the Neoplatonic manner, and, like the mediæval 'Aristotelianism,' brought more veneration than understanding to the interpretation of the philosopher. Of all Plato's disciples (to adapt a famous saying) perhaps only one had understood him—Aristotle—and he did not. His criticisms are often strangely unsympathetic. Yet Aristotle's whole system gives a more trustworthy clue to Plato's real philosophical significance than is to be got from mystical interpreters whose zeal was not always according to knowledge (see ARISTOTLE).

The first printed edition of the Greek text of Plato is the Aldine (Venice, 1513). Plato is constantly cited according to the pages of the edition printed by H. Stephanus (Paris, 1578). The best and most convenient texts are those of Stallbaum, of Baiter, Orelli and Winckelmann, and of K. F. Hermann. The critical edition by Schanz is not yet completed (1891). Plato was first printed in the Latin translation by Ficino (Flor. 1483), which was the best outcome of the Platonic revival, and is the basis of the ordinary Latin versions. A complete English translation was published by Thomas Taylor, 'the Platonist'—i.e. Neoplatonist, in 1804 (including nine dialogues translated by Sydenham about 1759). The poet Shelley translated the *Symposium* (included

along with other fragments of Platonic translations in Mr Buxton Forman's edition of his *Works*). Professor Jowett has made Plato an English classic (*Trans. with Introductions*, 2d ed. 5 vols. 1875; *The Republic*, separately, 3d ed. revised 1888). In the 'Golden Treasury' series are included translations of *The Republic* by Davies and Vaughan, of the *Euthyphro, Apology, Crito, Phædo* (under title *Trial and Death of Socrates*), by F. J. Church, and of the *Phædrus, Lysis, and Protagoras*, by Josiah Wright. Among more important English editions of separate dialogues may be named the *Apology*, by Riddell; *Phædrus* and *Gorgias*, by Thompson; *Philebus*, by Badham and by Poste; *Theætetus, Sophist, Statesman*, by Campbell; *Phædo* and *Timæus*, by Archer-Hind; *Phædo*, by Geddes; and the *Republic*, by Jowett and L. Campbell (1894). Among works on Plato's philosophy may be named Grote's *Plato;* Whewell's *Platonic Dialogues* (1860); Zeller's *Plato;* W. Pater's *Plato and Platonism* (1893); T. B. Strong's *Platonism* (1896); Bussell's *The School of Plato* (1896); and the relevant sections in the Histories of Philosophy by Schwegler, Ueberweg, Erdmann. Lutoslawski in *The Origin of Plato's Logic* (1897) rearranged the order of Plato's works on the ground of style alone, the doctrine of the ideas as objective existences being, he asserts, but a passing phase. For Plato's influence on Christian theology, see Hatch's Hibbert Lectures (1888); Bigg, *The Christian Platonists of Alexandria* (1886). For the Cambridge Platonists, see the articles LATITUDINARIANS, CUDWORTH, MORE, SMITH (JOHN), WHICHCOTE.

Platoff, MATVEI IVANOVICH, COUNT, was born at Azov, 17th August 1757. He served in the Turkish campaign of 1770–71, and in subsequent wars showed such capacity and courage that he was named by Alexander I. in 1801 Hetman of the Cossacks of the Don. As such he took part in the campaigns against the French, 1805–7, and, after the enemy had evacuated Moscow, hung upon their rear with pitiless pertinacity, wearing them out by incessant attacks, cutting off straggling parties, and capturing their convoys of provisions. He defeated Lefebvre at Altenburg, 28th May 1813. After the French disaster at Leipzig he harassed their retreat on French soil, gained a victory at Laon, and made his name memorable by the devastations of his hordes of semi-savages. He was enthusiastically welcomed, and presented with a sword of honour on the occasion of his visit to London in company with Blücher. The czar gave him the title of Count in 1812. After the war he retired to his own country, and died near Tcherkask, 15th January 1818.

Platonic Love, the love of soul for soul, a love into which sensual desire is supposed not to enter at all. See the last paragraph but one in the article PLATO.

Platt-Deutsch, or LOW GERMAN, the direct descendant of Old Saxon, and a sister-tongue of High German, is spoken to-day in different dialects by the peasantry of north Germany from the Rhine to Pomerania. It belongs to the same group as Dutch, Flemish, and Frisian. Low German softens the consonants, but avoids the deep sibilants of High German as spoken in the south, and has simple grammatical rules. It is very appropriate in the mouths of the people who use it, their chief characteristics being naïveté, a childlike good-nature, and sturdy honesty; and it lends itself readily as a vehicle for fairy-tales, folk-tales, and simple folk-songs, such as those collected in Firmenich's *Germaniens Völkerstimmen*. Klaus Groth (q.v.) and Fritz Reuter (q.v.) have given it a high literary standing. Minor writers in Low German are Bornemann, Burmeister, Giesebrecht, and Brinckmann.

See Groth, *Briefe über Hochdeutsch und Plattdeutsch* (1858); and Gaedertz, *Das Niederdeutsche Schauspiel* (2 vols. 1884). See also the articles GERMANY (LANGUAGE AND LITERATURE), GRIMM'S LAW, EULENSPIEGEL, REYNARD THE FOX.

Platte, or NEBRASKA, an affluent of the Missouri River, is formed by the junction in west central Nebraska of the North and South Forks, which rise among the Rocky Mountains, in Colorado, are respectively some 800 and 550 miles long, and are neither of them navigable. The general course of the Platte is eastward, in a wide shallow stream, over the treeless plains of Nebraska, till it reaches the Missouri after a winding course of about 450 miles. With its forks it drains some 300,000 sq. m., but like them it is not navigable.

Platten-See. See BALATON.

Plattsburg, capital of Clinton county, New York, on Lake Champlain, at the mouth of the river Saranac, 73 miles by rail S. of Montreal. It has planing-mills, machine-shops, and an iron-furnace, and manufactures wagons and sewing-machines. In Plattsburg Bay, on September 11, 1814, a British flotilla of sixteen vessels was defeated and partly captured by Commander Thomas Macdonough, with fourteen vessels; while a large land force, under Sir George Prevost, was repulsed by General Macomb, with 1500 men. Pop. 5245.

Plattsmouth, capital of Cass county, Nebraska, is on the Missouri, about a mile below the mouth of the Platte, and 21 miles by rail S. of Omaha. It manufactures flour, wagons, engines, reed-organs, &c. Pop. (1880) 4175; (1890) 8392.

Platypus. See ORNITHORHYNCHUS.

Plauen, one of the most important manufacturing towns of Saxony, stands in the south-west corner, on the Elster, 78 miles S. of Leipzig by rail. Its chief industries are the manufacture of cotton goods, muslin, cambric, jaconet, and embroidered fabrics, with in a secondary degree cigars, paper, machinery. Pop. (1875) 28,756; (1890) 46,899.

Plautus, M. ACCIUS (or more correctly *T. Maccius*), the chief comic poet of Rome, and probably among his own countrymen the most popular Roman author of any age, was born about 250 B.C. at Sarsina, a village in Umbria, a district which must at this time have been thoroughly Latinised. We have no knowledge of his early life and education, but it is probable that he came into Rome while still young, and acquired there his complete mastery of the most idiomatic Latin. Though born in the country, he introduces countrymen chiefly as subjects for ridicule; he always writes as a townsman, familiar with city life, especially among freedmen, craftsmen, and the middle classes. At Rome he found employment in connection with the stage, of what kind precisely we do not know. In this position he saved money enough to enable him to leave Rome and start in business on his own account in the way of foreign trade; and such early thrift shows strong character and determination to rise in the world. His plays evince close familiarity with seafaring life and adventure, and an intimate knowledge of all the details of buying and selling and keeping accounts—experience probably acquired during this period. We know that he failed in business, and returned to Rome in such poverty that he had to earn his livelihood in the service of a baker by turning a hand-mill, work generally performed by slaves. At this time, shortly before the second Punic war broke out, he was probably about thirty years of age, and while in this humble occupation he composed three plays which he sold to the managers of the public games. The price paid him enabled him to leave the mill, and he spent the rest of his life at Rome. Probably he commenced to write about 224 B.C., and for forty years, until his death in 184, he continued to produce comedies with wonderful fecundity. Most of the plays we have belong to the last ten years of

his life. It is not certain whether Plautus ever obtained the Roman franchise. He was the contemporary of Nævius and of Ennius.

His plays appear not to have been published during his lifetime, but to have been left in the hands of the actors, who probably both interpolated and omitted passages to suit them for the stage. Almost all the prologues were written after his death. About 130 plays were attributed to him in the time of Gellius, who held most of them to be the work of earlier dramatists, revised and improved by Plautus. Roman critics considered most of them to be spurious. Varro in his treatise *Quæstiones Plautinæ* limited the genuine comedies to twenty-one; and these so-called 'Varronian comedies' are the same which we now possess, only one, the *Vidularia*, being lost. Plautus' plays were immensely popular on the stage, not only with the people, but with the educated classes, and were acted, as Arnobius tells us, in the time of Diocletian, five centuries later. Plautus borrowed his plots to a large extent from the New Attic Comedy, which dealt with social life to the exclusion of politics; he doubtless imitated its general types of character, but he 'adapted' very freely, and infused into his borrowed framework a new and robuster life, which was Roman to the very core. His perfect spontaneity, vivacity, and vigour of language, and the comic power of his dialogues, show that these are the genuine fruit of his own genius. The scenes of his comedies are always laid in Athens or in some Greek town. Had he depicted the family life of Romans as so corrupt, the magistrates would no doubt have interfered; but the Greek personages of his plays speak and act in every respect like Romans; they refer familiarly to places in Italy, to streets, magistrates, and customs at Rome. Not even Shakespeare is more careless about inconsistency of this kind. It is probable that Plautus wrote with great rapidity; some of his finest comedies are spoilt through the action being too hurried towards the close. Roman comedy expressed 'a rebound from the severer duties of life;' Plautus' audience were in holiday mood, and did not expect to be admonished as to duty or entertained with serious reflection. His leading characters possess boundless animal spirits, infinite resource in difficulty, and but small conscience. His heroines show that, as Sellar says, Plautus was more familiar with the ways of 'libertinæ' than of Roman ladies. His favourite subject is a plot by which a slave, on behalf of his young master and the mistress of the latter, cheats a father or some one else. Plautus shows no feeling for nature, though he is fond of describing the sea in calm and storm; his lack of any sense of natural beauty and of high imagination makes a deep gulf between him and Aristophanes. Yet he shows distinct creative power, as in the character of Euclio the miser in the *Aulularia*, who, though entirely possessed by his one idea, is still honest and independent and not contemptible. Fine touches are not wanting. In the *Captivi* the slave Tyndarus, cheerfully willing to sacrifice all for his young master, shows that Plautus had the power to conceive a really noble character. The charm of Plautus, lying in his genuine humour and powerful grasp of character, goes deep down to the roots of human nature; he delights his readers to-day as truly as when he made Roman theatres ring with applause, or when St Jerome solaced himself in his cell by reading the well-loved comedies. His joyous sense in all circumstances of the gladness of life is the sign of a strong and manly nature; he makes his reader look involuntarily at the bright side of things. According to Sellar, the five best plays are *Aulularia*, *Captivi*, *Menæchmi*, *Pseudolus*, *Rudens*. Shakespeare has imitated the plot of the *Menæchmi*, entirely recasting it, in his *Comedy of Errors*. Molière's *L'Avare* is borrowed from the *Aulularia*.

English translations are by Thornton and Warner (1767–74), and H. T. Riley (1880). Ritschl has shown great acuteness in restoring Plautus' text, which is very corrupt (2d ed. 1871). The complete edition which he contemplated was continued by his pupils, G. Goetz and others (1878 *et seq.*). See also Sellar, *Roman Poets of the Republic*.

Playfair, JOHN, mathematician and natural philosopher, was born at Benvie manse, near Dundee, March 10, 1748, and studied at St Andrews. In 1773 he succeeded his father as minister of Liff and Benvie. During his leisure hours he still prosecuted his favourite mathematical and geological studies, and communicated to the Royal Society of London two memoirs, *On the Arithmetic of Impossible Quantities* and *Account of the Lithological Survey of Schiehallion*. In 1785 he became joint-professor of Mathematics in Edinburgh University, but exchanged his chair for that of Natural Philosophy in 1805. He became a strenuous supporter of the 'Huttonian theory' in geology, and, after publishing in 1802 his *Illustrations of the Huttonian Theory of the Earth* (see GEOLOGY, Vol. V. p. 148), he made many journeys for the sake of more extensive observations, particularly in 1815, when he visited France, Switzerland, and Italy. He died at Edinburgh, 19th July 1819. Playfair was during the later part of his life secretary to the Royal Society of Edinburgh. From 1804 he was a contributor to the *Edinburgh Review* and to the *Transactions of the Royal Society of Edinburgh*, and wrote many important articles for the *Encyclopædia Britannica*. His separate works are the *Elements of Geometry* (1795) and *Outlines of Natural Philosophy* (1812–16).

Plays. See DRAMA, THEATRE. A relic of the censorship of the press survives in Britain in the licensing of stage plays. By an Act of 1843 no plays may be acted for hire till they have been submitted to the Lord Chamberlain, who may refuse to license them in whole or in parts; the official who reads them for this purpose being the 'examiner of stage plays.' A penalty of £50 attaches to the offence of acting an unlicensed or prohibited play; and the theatre in which it is represented forfeits its license. In the United States there is no general censor, but local authorities have power to forbid the representation of plays which they consider to be hurtful to morality.

Plea, the answer of the defendant to the plaintiff's demand or charge. Pleas were divided formerly into pleas dilatory (where the party seeks to break down the conclusion of the action without entering into the merits of the case) and peremptory, Demurrers (q.v.), in Abatement (q.v.), special in bar, &c.; now the plea is usually Guilty or Not Guilty (see CRIMINAL LAW). In Scots law, plea means also a written statement by counsel of the legal grounds on which the party bases his case. In English civil procedure this is called *Pleading;* a term applied in criminal law to the accusation of the prosecutor or the answer of the accused. Pleadings have been much simplified by the Judicature Acts (1873–76). In the United States the New York legislature established a uniform procedure which has been adopted by most of the states. 'Pleas of the Crown' is an old term for criminal cases. In the Houses of Parliament pleading, as in the superior courts of law, must be conducted at the Bar (q.v.).

Plebeians. See ROME, TRIBUNE.

Plebiscite, the name given, in the political phraseology of modern France, to a decree of the

nation obtained by an appeal to universal suffrage. Thus, Louis Napoleon was chosen president, and subsequently emperor, by a plebiscite, and in 1870 obtained the sanction of still a third one (7½ million votes). The word is borrowed from the Latin; but the *plebiscitum* of the Romans properly meant only a law passed at the *Comitia Tributa*—i.e. assembly of the *plebs*, or 'commons,' as distinguished from the nobles. The word is often used in Britain for an attempt to secure an expression of opinion on some special point of local interest by all the inhabitants of a district—often by means of return post-cards.

Plectognathi, an order of Bony Fishes (q.v.).

Pledge. See PAWNBROKING.

Pleiades, in Greek Mythology, were, according to the most general account, the seven daughters of Atlas and Pleione, the daughter of Oceanus. Their history is differently related by the Greek mythologists: according to some authorities, they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of their father, Atlas (q.v.); according to others, they were companions of Artemis (Diana), and, being pursued by Orion (q.v.), were rescued from him by the gods by being translated to the sky; all authorities, however, agree that after their death or translation they were transformed into stars. Their names are Electra, Maia, Taygete, Alcyone, Celæno, Sterope (the invisible one), and Merope. The group or constellation of the Pleiades, called the 'Seven Stars,' is placed on the shoulder of Taurus, the second sign of the Zodiac, and form, with the pole-star and the twin Castor and Pollux, the three angular points of a figure which is nearly an equilateral triangle. But, if looked at directly, only six stars are visible to the eye, though, if the eye is turned sideways, more can be seen; a good telescope shows fifty or sixty in the area. The photographic chart produced by M.M. Henry in 1888 shows 2326 stars, with nebulæ intermixed.

The name *Pleiad* is frequently applied to reunions of poets in septenary groups; and this use of the word dates from the time of Ptolemy Philadelphus at Alexandria, who treated seven Greek poets with special distinction, and denominated them his *pleiad*. His example was followed by Charlemagne. But the name *Pléiade* is specially associated with a group of 16th-century French writers, of whom Ronsard (q.v.) and Du Bellay (q.v.) are the most notable, who endeavoured with marked result to reform the French language and literature after classical models. The other names are Lazare de Baïf, ambassador at the diet of Spires; Jean Dorat, a celebrated Hellenist; Amadis Jamin; Etienne Jodelle; and Pontus de Thiard. In place of the two last, other authorities give Scévole de Saint Marthe and Marc Antoine Muret (q.v.); and instead of Jamin, Belleau.

Pleiocene. See PLIOCENE.

Pleiochroism. In some crystals, such as some specimens of topaz, three distinct colours may be observed on looking through them along three rectangular axes. In intermediate directions intermediate tints may be observed; and this property is that of pleiochroism or polychroism. In some other cases a similar range of intermediate tints may be observed, lying between two extreme tints visible along two axes (dichroic crystals—e.g. iolite or *sapphire d'eau*, and some specimens of mica).

Pleiosaurus. See PLESIOSAURUS.

Pleistocene (Gr., 'most recent') or GLACIAL SYSTEM. This system comprises the older accumulations belonging to the Quaternary or Post-Tertiary division. Almost all the molluscs met with in beds of this age are existing species. The system is termed Pleistocene or Glacial according as we have reference to the character of its organic remains or to the physical conditions under which the greater portion of its deposits were accumulated. These deposits are of very diverse nature and origin, and are subject to endless modifications, but nevertheless they show certain well-marked phases which are persistent over wide areas. Thus, throughout all northern Europe and the hilly and mountainous districts of the central and southern regions of the continent they exhibit the same general character and succession. The deposits of these regions consist for the most part of glacial and fluvio-glacial detritus, which betoken the former presence of a great ice-sheet in northern Europe, and of extensive snowfields and glaciers in the mountain districts farther south. For an account of these deposits and glaciation generally, see GLACIAL PERIOD. In the regions outside of the glaciated areas the Pleistocene system is represented principally by fluviatile accumulations, calcareous tufas, peat, and deposits in caves. The old river-gravels, &c. are well seen in the valleys of southern England, France, Belgium, central Europe, Spain and Portugal, Italy, &c., where they occur at the surface. But when they are followed into regions in which glacial and fluvio-glacial accumulations are well developed they disappear underneath these or are dovetailed with them. Cave-deposits are of course met with even in glaciated regions, but in such countries no Pleistocene accumulations overlie the glacial and fluvio-glacial detritus of the latest cold stage of the glacial period.

Thus, in general terms, the Pleistocene deposits of northern Europe and the mountainous regions of the central and southern parts of the continent are of glacial origin, while the accumulations outside of those areas are chiefly fluviatile. The latter were for some time believed to be upon the whole younger than the former, but the two series are now generally recognised to be contemporaneous. The occurrence of fossiliferous beds intercalated between sheets of morainic matter (boulder-clay, &c.) proves that the so-called glacial period was interrupted more than once by epochs of milder climatic conditions, during which the inland ice of the north retired from all the low grounds, while the great glaciers of the Alps, &c. shrank back to the inner recesses of the mountains. The organic remains obtained from fresh-water interglacial deposits have been correlated with those which occur in the river-accumulations of the non-glaciated tracts, and the result is that these accumulations are now admitted to be for the most part of interglacial age also. In short, the peat, river-deposits, tufas, and cave-accumulations are the equivalents in time of the glacial and interglacial deposits.

Life of the Period.—The plants and animals of the Pleistocene betoken great changes of climate—one series indicating an extremely cold or Arctic climate, while the other could only have flourished under extremely clement and uniform conditions. While a cold climate prevailed, such plants as *Dryas octopetala*, *Betula nana*, *Salix polaris*, &c. flourished in the plains of Germany, and similar northern and Arctic forms clothed the low grounds of Switzerland. In northern France grew birch, alder, larch, spruce, juniper, and yew, while in Northern Italy the Cembran pine flourished in the neighbourhood of Ivrea, and the Scotch fir on the shores of Lake Varese, positions in which it is needless to say they could not live now. Contemporaneous with this flora we meet with land and fresh-water shells which are equally indicative of cold and ungenial conditions. And the same tale

is told by the boreal and Arctic species of molluscs which occur more or less abundantly in the shelly clays of north Germany, Scandinavia, and the British Islands, and by the presence of northern forms in the Pleistocene marine beds of the Mediterranean area. The character of the land animals is quite in keeping with this evidence. Living in the low grounds of central and southern Europe at this time were reindeer, glutton, musk-sheep, Arctic fox, Alpine hare, marmot, snowy vole, mammoth, woolly rhinoceros, &c. The remains of these northern and Arctic plants and animals are met with both in glaciated countries and in the caves and fluviatile deposits that occur in regions that never were covered with glacier-ice. The relics and remains of man himself also accompany the same flora and fauna. In strong contrast with such an assemblage of plants and animals is that of which we find abundant traces in interglacial beds and cave- and river-deposits. In northern France grew willows, hazels, ash, dwarf elder, sycamore, spindle-trees, perfumed cherry-tree, box, clematis, common ivy, judas-tree, Canary laurel, &c. The presence of that laurel, which flowers in winter, proves that the winters must have been very clement, and the other plants are indicative of a genial humid climate. The summers were not so hot and dry as they now are in France, and the winters were not so cold; and similar conditions obtained in Germany and the Mediterranean region—although the floras of those different zones were distinguished from each other by the presence of certain forms and the absence of others. The land and fresh-water shells associated with this flora are equally indicative of genial conditions, and similar evidence is supplied by the mammalia. Thus, we find a strange commingling of southern and temperate forms which is quite in keeping with the similar association in one and the same place of various plants which no longer live together in Europe. Amongst the animals were hippopotamus, African elephant, hyæna, serval, lion, leopard, various extinct species of elephant and rhinoceros, an extinct dwarf hippopotamus and machairodus. Contemporaneous with these were urus, bison, horse, stag, roe, saiga, beaver, hare, rabbit, otter, weasel, wild-cat, fox, wild-boar, brown bear, grizzly bear, cave-bear, Irish deer, &c. The relics and remains of Palæolithic man likewise accompany this flora and fauna.

It is obvious, therefore, that the Pleistocene period was distinguished by great climatic oscillations. At one time the whole of northern and north-western Europe, down to the 50th parallel N. lat., was covered with a vast *mer de glace*, while from the Alps and all the considerable mountain-ranges of middle and southern Europe great glaciers descended to the low grounds. From ice-sheet and glaciers mighty rivers flowed all the year round, but in summer they rose in flood and inundated wide tracts, which in time became overspread with sand and loam. It was under such conditions that a boreal and Arctic vegetation clothed the low grounds of middle Europe. Considerable tracts of that region, during the last cold stage of the glacial period, appear to have resembled steppes, and to have been inhabited by jerboas (jumping hare), spermophiles, &c. The same lands, which in some places were clothed with pine-forests, were roamed over by great herds of reindeer, mammoths, &c.—the bones of which sometimes occur together in such large numbers as to lead to the belief that the animals may have perished in snow-storms or 'blizzards.' It was then, too, that the reindeer and its associates flourished in the low grounds of southern France, where they were hunted by Palæolithic man. With the advent of interglacial times such ungenial conditions of climate passed gradually away—the ice-sheet vanishing from the low grounds of north-western Europe, while the mountain-glaciers of central and southern regions dwindled to insignificance. Great migrations of plants and animals accompanied these changing conditions, the Arctic-alpine flora and northern and alpine fauna retreating northwards and retiring to mountain elevations. At the climax of interglacial times an extremely mild and genial climate, recalling that of the Pliocene, prevailed in Europe. The Canary laurel, the fig-tree, the judas-tree, and many others flourished then as far north as Paris, in which region frost in winter was rarely or never experienced. Elephants, hippopotamuses, rhinoceroses, &c., and vast herds of bovine and cervine animals then wandered over all temperate Europe—the British area included. How often such changes of climate were repeated has not yet been ascertained, but interglacial beds occur on at least two horizons—as in France and the alpine lands of central Europe. Hence there would appear to have been at least three glacial epochs separated by two intervening epochs of genial climatic conditions. In northern Europe only one well-marked interglacial epoch is generally admitted by geologists. But the evidence is not conclusive. It is obvious, indeed, that the preservation of interglacial accumulations must have been exceptional within regions which have been severely glaciated. With the return of ice-sheet and glaciers, fluviatile and other deposits which had been laid down during interglacial times would be ploughed up and commingled with other morainic material. It is only here and there, therefore, that patches of such deposits have escaped destruction. The relics of interglacial times are most abundantly met with in countries which were beyond the reach of the ice. The closing stage of the Pleistocene was a glacial one; so that in the valleys of central and western Europe the ossiferous river-gravels of the last interglacial period are more or less buried under the fluvio-glacial gravels and loams of the latest glacial epoch. The latest Pleistocene deposits in the British area are marine clays containing Arctic and boreal shells. These deposits go up to 100 feet or so in Scotland.

Considerable geographical changes supervened during Pleistocene times. The proofs are seen in certain raised beaches in the maritime districts of north-western Europe, in the marine clays with their Arctic and boreal shells, and the marine sands, &c. of glacial and interglacial age, which are well developed in the British area. Again, the distribution of the mammalian fauna of the Pleistocene points in like manner to considerable changes in the relative level of land and sea. Thus it would appear that in interglacial times Europe was connected, across the Mediterranean, by one or more land passages with north Africa; while at the same time the British area was continental. Indeed, certain evidence leads to the belief that the European lands stretched out into the Atlantic as far as what is now the line of 100 fathoms. Towards the close of the last interglacial epoch, however, a considerable submergence of the British area supervened—for undisturbed interglacial shell-beds have been met with up to heights of several hundred feet. It is noteworthy also that the low grounds of north Germany were likewise submerged just before the invasion of that region by the last great *mer de glace*. The cause of such changes of level has been much canvassed by geologists. From the fact that evidence of submergence so frequently accompanies proofs of severe glaciation, it has been inferred that the subsidence may have been due to the presence of the ice. It has been suggested, for example, that

the weight of the great ice-sheets which covered such vast regions in our hemisphere during glacial times may have displaced the earth's centre of gravity, and thus caused a rise of the sea in the north. Others, again, think it probable that under the pressure of a great ice-sheet the earth's crust may have yielded and sunk down more or less gradually. Some, again, have thought that a thick ice-sheet would exercise sufficient attraction upon the sea to cause it to rise upon the land. It must be admitted, however, that some of the oscillations of level which took place in Pleistocene times were on much too considerable a scale to be explained by any of the hypotheses referred to. If, for example, the considerable submergence which happened just before the advent in the British area of the last *mer de glace* was due to the pressure of an ice-sheet covering some region farther north, it is hard to understand how great confluent glaciers afterwards succeeded in covering an area lying several hundred feet below the surface of the sea. Again, if the crust of the earth were so readily deformed under the weight of an ice-sheet, how shall we explain the absence of any traces of contemporaneous marine action in those low-lying regions of south England and the Continent which were invaded by the great northern ice-sheet? Whatever influence the ice-sheets of the glacial period may have had upon the sea-level, it seems most probable that the greater oscillations were the result of considerable earth-movements, such as have taken place at many different stages of the world's history.

Pleistocene in other Continents.—In North America deposits of the same character and showing the same general succession as those of Europe are encountered—the glacial and interglacial conditions that characterised the latter continent having been equally characteristic of the former. The Pleistocene fauna of North America embraced Mastodon, a true elephant, species of horse, bison, beaver, peccary, bear, &c., and gigantic extinct forms of sloth, such as Megatherium, Mylodon, and Megalonyx. In South America the Pampa deposits have yielded a large number of remains of the great sloths and armadillos (Glyptodon), besides other mammals. There is abundant evidence also to show that snow-fields and glaciers had in Quaternary times a considerable development in the Cordilleras, while in Fuegia ice seems to have overflowed much of the low grounds. In South Africa former snow-fields and glaciers have left their traces in the Kaga and Krome mountains. So, again, New Zealand and Australia seem to have had a glacial period. Little is known of the mountains of central Asia, but old moraines and erratics have frequently been observed in the Chinese ranges, while, as is well known, the glaciers of the Himalayas had formerly a very great development.

Cause of the Pleistocene Climatic Changes.—Many speculations as to the cause of the climatic changes of Pleistocene times have been indulged in. It must be admitted, however, that none of these explanations is without its difficulties. But the theory which best accounts for the facts and has gained the widest acceptance is that advanced by the late Dr Croll. According to him, the strongly contrasted climates of the Pleistocene period were the indirect result of the increased eccentricity of the earth's orbit, combined with the precession of the equinox. During a period of high eccentricity that hemisphere which had its winter in aphelion would be subject to severe cold, and its snows would not disappear during the succeeding short summer, the temperature of which would be lowered by its presence. Thus in time that hemisphere would be subjected to severe glacial conditions. In the opposite hemisphere the state of things would be very different, for the winter would be short and mild and snow would not accumulate. Under such widely contrasted conditions between the northern and southern hemispheres, the trade-winds, and through them the great equatorial ocean-currents, would be powerfully affected. The winds blowing from the glaciated hemisphere would be much stronger than those coming from the other, and the equatorial oceanic currents would thus be impelled across the equator into that hemisphere whose summer happened in aphelion. This influx of warm water would necessarily increase the temperature of that hemisphere, while the other would have its temperature correspondingly lowered. Owing to the precession of the equinox, however, the conditions of the two hemispheres would tend to be reversed every 11,000 years or so; so that during a cycle of great eccentricity each hemisphere would experience an alternation of extremely cold and very genial climatic conditions. The last period of high eccentricity commenced some 240,000 years ago and lasted for about 160,000 years. Some geologists have objected that the glacial period cannot be carried so far back in time. Thus, from an examination of the rate of erosion in the postglacial gorges of some rivers in North America (Falls of Niagara, Falls of St Anthony), some observers conclude that only 7000 or 8000 years have elapsed since the close of the ice age. But in all such measurements and estimates there are elements of uncertainty which render the conclusions based upon them of little value.

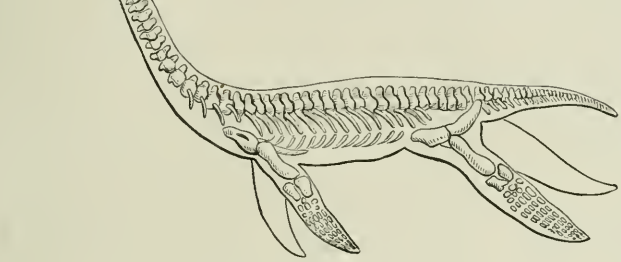
Antiquity of Man in Europe.—All the human relics met with in Pleistocene deposits belong to what is known as the Palæolithic stage. Hitherto no indubitable evidence is forthcoming to show that man was an occupant of Europe before the glacial period. It is quite possible he may have been, but we lack evidence sufficient to prove this. He certainly lived, however, throughout the glacial and interglacial conditions described above. It is remarkable that no trace of his occupation has been met with in beds of later date than those pertaining to the close of the last interglacial epoch. If we were to judge from negative evidence (which it is always unsafe to do) we should infer that he vanished from Europe during the last glacial epoch. The oldest human relics hitherto discovered in postglacial beds are Neolithic.

See Croll's *Climate and Time* (1875). Various objections which have been urged against this theory have been answered by its author in his *Climate and Cosmology* (1886). See also G. F. Wright, *The Ice Age in North America* (1889), and the articles in this work on GEOLOGY, ANTHROPOLOGY, MAN, EUROPE, STONE AGE.

Plenipotentiary. See AMBASSADOR.

Plesiosaurus (Gr. *plesios*, 'near to,' *sauros*, 'a lizard'), the type or leading genus of a family (Plesiosauridæ) of fossil sea-reptiles, which are characteristic of the Mesozoic systems. The skull of Plesiosaurus is small and depressed, with a short mandibular symphysis. The teeth (sunk in distinct sockets) are long, slender, and cylindrical, and show fine longitudinal ridges on the enamel. The most striking peculiarity of the vertebræ is the great length of the neck portion, which was composed of from 24 to 41 vertebræ—the anterior ones being generally very small. The cervical vertebræ consist of a centrum, neural arch, and two ribs, which are firmly articulated to the centra of the vertebræ, the terminal faces of which are more or less biconcave. In the dorsal vertebræ the ribs are articulated to diapophyses from the neural arch; and in the tail they gradually descend again to the sides of the centrum. The tail is

much shorter than in Ichthyosaurus (q.v.). In the abdominal region the extremities of each pair of ribs are connected below by the development of the hæmal spine. The scapulæ are of moderate size and widely separated. The two pairs of limbs correspond closely in structure. The humerus and femur are comparatively short and distally much expanded; the radius and ulna, tibia and fibula are short and flat; the 'hand' and 'foot' are long, the phalangeals being increased in number beyond the normal complement. The limbs were covered with integument so as to form simple undivided paddles, as in the turtle. Plesiosaurus was undoubtedly aquatic, and probably haunted the shallow seas and estuaries of Mesozoic times. Its remains have been met with frequently in a fine state of preservation, some almost perfect skeletons having been obtained from the Lias of England. Several genera of Plesiosauridæ have been determined. One of these, Cimoliosaurus, met with



Plesiosaurus dolichodeirus.

in the Jurassic and Cretaceous strata of Europe, North and South America, and New Zealand, attained a length of between 30 and 45 feet. Pliosaurus was another genus, with a shorter neck (the vertebræ twelve in number) and a comparatively larger head than Plesiosaurus. In this genus the lower jaw was sometimes nearly 6 feet long. See the *Manual of Palæontology*, by Nicholson and Lydekker (1889).

Plessis-les-Tours. See TOURS, LOUIS XI.

Plethon, GEORGIOS GEMISTOS, a Greek scholar, was most probably a native of Constantinople, and found employment in the Peloponnesus under the 'despots' Manuel and Theodore Palæologus. He was sent as a deputy to the council held at Florence in 1439, and here, if he did little for the union of the Eastern and Western Churches, he did much to spread a taste for Plato. He returned to Constantinople, and died there about 1455. See vol. i. of F. Schultze's *Geschichte der Philosophie der Renaissance* (Jena, 1874).

Pleth'ora (Gr., 'fullness') designates a general excess of blood in the system. It may arise either from too much blood being made or from too little being expended. The persons who become plethoric are usually those in thorough health, who eat heartily and digest readily, but who do not take sufficient bodily exercise, and do not duly attend to the action of the excreting organs. With them the process of blood-making is always on the increase, and the vessels become more and more filled, as is seen in the red face, distended veins, and full pulse. The heart is excited and overworked, and hence palpitation, shortness of breath, and probably a sleepy feeling may arise; but these symptoms, instead of acting as a warning, too often cause the abandonment of all exercise, by which the morbid condition is aggravated. The state of plethora thus gradually induced may be extreme without any functions materially failing, and yet the subject is on the verge of some dangerous malady, such as apoplexy, or structural disease of the heart or great vessels, or of the lungs, kidneys, or liver.

Pleurisy, or inflammation of the investing membrane of the lung (*pleura*), is one of the most serious diseases of the chest. It is very often, but by no means invariably, associated with inflammation of the *substance* of the lung, commonly known as *Pneumonia* (q.v.). Pleurisy without pneumonia is much more common than pneumonia without pleurisy. When both are present, but pneumonia preponderates, the correct term for the affection is *pleuro-pneumonia*, although it is frequently spoken of simply as pneumonia, probably in consequence of the remedies being applied mainly to it, as the more important of the two elements in the compound malady.

The pleura being a serous membrane, its inflammation is attended by the same course of events as have been already described in our remarks on the two allied diseases, *Pericarditis* and *Peritonitis*. The inflammation is of the adhesive kind, and is accompanied by pain, and by the effusion of serum, of fibrinous exudation, or of pus into the pleural cavity. In the last case it is called *empyema*. In consequence of the anatomical relations of the pleura—one part of the membrane (the parietal) lining the firm walls of the chest, while the other part (the visceral) envelops the soft and compressible lung, and these opposed surfaces being freely movable on one another—it follows that very different effects may be produced by its inflammation. For example, the visceral layer may be glued to the parietal layer, so as to prevent all gliding movement between them, and to obliterate the pleural cavity (similarly to what often happens in *Pericarditis*, q.v.); or the two surfaces which are naturally in contact may be abnormally separated by an effusion of serum between them; or, from a combination of these results, the opposite surfaces of the pleuræ may be abnormally united at some points, and abnormally separated at others.

The general symptoms of pleurisy are rigors, pain in the side, fever, difficulty and rapidity of breathing, cough, and an impossibility of assuming certain positions; and of these the most marked is the pain or *stitch in the side*, the *Point de côte* of the French writers. The pain, often very severe, and often limited to one small spot, is usually at the lower part of the affected side; but is occasionally felt in other parts—as in the shoulders, in the hollow of the armpit, beneath the collar-bone, along the breast-bone, even in the loins, simulating lumbago; or, in the abdomen, so as to suggest peritonitis or hepatitis. In some cases it is altogether absent. The pain is increased by percussion, by pressure between the ribs, by a deep inspiration, by cough, &c.; and the patient is often observed never to draw more than a short and imperfect inspiration. Cough is not invariably present, although it is an ordinary symptom. It is small, suppressed as far as possible by the patient, and is either dry or accompanied by the expectoration of slight catarrh. If much frothy mucus is brought up it is a sign that Bronchitis (q.v.) is also present, and the appearance of rust-coloured sputa indicates the co-exist-

ence of pneumonia. Although the above-named symptoms, especially when most of them occur together, afford almost certain evidence of the existence of pleurisy, yet to the physician the physical signs are still more valuable, especially those furnished by auscultation and percussion. The *friction-sound*, characteristic of pleurisy in the dry stage in its most marked form, resembles the creaking of leather: the patient is often himself conscious of the grating sensation produced by the rubbing of the pleural surfaces; and it may sometimes be felt by a hand laid on the affected part. If fluid effusion be present the friction-sound is lost; but dullness on percussion replaces the normal resonance over the area which it occupies.

Pleurisy far more commonly arises from exposure to cold than from any other cause, especially if a poisoned condition of the blood, predisposing to inflammation of the serous membrane, is present; thus it often complicates rheumatic fever and Bright's disease; but it may be occasioned by mechanical violence (as by a penetrating wound of the thorax, by the splintered ends of a broken rib, &c.), or by the accidental extension of disease from adjacent parts. The disease may terminate in resolution and complete recovery; or in adhesion, which often only causes slight embarrassment of breathing; or it may end with such a retraction of one side of the chest as to render the corresponding lung almost or totally useless; or it may cause death either directly by actual suffocation, if the effusion is very copious, and is not removed by tapping, or indirectly, by exhaustion. It is seldom that simple pleurisy proves fatal; but empyema in adults is a very fatal disease.

In the treatment of pleurisy rest in bed, careful nursing, and light diet are essential. In acute cases in the early stage cupping, leeching, or blistering is generally indicated. When effusion has taken place, purgatives, diuretics, and absorbents should be given. But when fluid is present in large amount and is not diminishing from day to day, it is usually desirable to draw it off by tapping. If the fluid be serous this usually greatly hastens recovery. Even when it is purulent (empyema) aspiration, repeated when necessary, is often successful in the case of children; but more generally, especially in adults, free antiseptic opening and drainage of the cavity alone affords any hope of cure.

Pleurisy Root. See BUTTERFLY WEED.

Pleurodynia is the name sometimes applied to neuralgia of the chest-wall, which may simulate closely the pain of pleurisy.

Pleuronectidæ. See FLAT-FISH.

Pleuro-pneumonia. The disease of this name in the human subject is mentioned at PLEURISY; the following article deals with the disease in cattle so called. Pleuro-pneumonia Contagiosa is a contagious febrile disease peculiar to horned cattle, supposed to have originated in central Europe and thence to have been conveyed to all parts of the world. It cannot be certainly traced further back than 1769, when it was known in eastern France as *Murie*. Not till 1802 was it seen in Germany, 1824 in Russia, 1841 in Great Britain and Ireland, 1843 in the United States, 1858 in Australia, and 1864 in New Zealand. It is due to a contagium which gains access to the system by the lungs, and which, after an incubative period of from two or three weeks to as many months, induces extensive inflammatory exudations in the substance of the lungs and surfaces of the pleura, finally resulting in consolidation of some portions of the lungs, occlusion of the air-tubes, plugging of the blood-vessels, and, generally, adhesion of the pleural surfaces.

It is now clearly demonstrated that pleuro-pneumonia never occurs independently of infection, that it is not fostered by overcrowding, exposure, wet, damp, dirty hovels: these influences may predispose an animal to succumb more readily, or, in other words, to become a more suitable soil for the increase of the specific organism to which undoubtedly the disease is due, as stated by the writer in 1886. He stated that the organism was a micrococcus. It has since been discovered that there are three kinds of micrococci—viz. 1st, *pneumococcus gutta-cerci*, whose colonies, when grown in artificial media, resemble drops of wax; 2d, *pneumococcus lichenoides*, which grows in a thin white layer; and 3d, *pneumococcus flaveus*, whose colonies are elongated or round in shape, and assume a beautiful orange tint. In addition to these cocci a bacillus is found, called by Arloing the *pneumobacillus liquefaciens*, and supposed by that observer to be the pathogenic organism causing the disease.

There is much variety in the manifestation of the disease. In some instances, especially during its first outbreak in a district, it runs a rapid course, destroying life in the course of a few days; in other cases, and these are the most numerous, its onset, course, and termination occupy a period of from two to eight weeks, or even longer; some animals recovering after the shorter periods, whilst others become emaciated, finally succumbing to an exhaustive diarrhœa, imperfect aeration of the blood, hydrothorax or water in the chest, the depressing influence of degenerated animal materials absorbed into the blood, and anæmia. The more prominent symptoms are slight rigors or shiverings, elevation of temperature, loss of appetite, secretion of milk diminished, an occasional cough is heard which is dry and hard in character, rumination becomes irregular, the bowels rather constipated, and the urine is scanty and high-coloured. In cases that do not begin to recover at this stage the signs of general disturbance more or less rapidly increase: the cough becomes more persistent, the respiratory movements increase in frequency, when the animal stands the elbows are turned out, and whilst recumbent the weight of the body is thrown upon the sternum or breast-bone—a posture in which, owing to the anatomical conformation of this bone, the animal can most readily expand the chest. The breathing is often but not always accompanied by a moan or grunt resembling the bleating of a goat.

Experience has led the great majority of professional men to the conclusion that the disease is not influenced by medicinal remedies; it runs a course. If the dose of the contagium is small, or the animal able to withstand a larger one, it terminates spontaneously in apparent recovery; but an animal which has thus apparently recovered still contains the germs and products of the disease, and remains a source of danger to others for an indefinite period, probably during the remainder of its existence. If, on the other hand, the dose of the specific cause be strong or the animal weak, death soon occurs. By the provisions of the Pleuro-pneumonia Act, 1889, all cattle suffering from the disease as well as those in contact with them have to be slaughtered, part of the loss being borne by the local authority.

Inoculation.—Experienced and successful inoculators are all agreed that inoculation with carefully selected lymph—and the non-success of the operation has been proved to be due to a careless selection of the inoculating fluid, and ignorance on the part of the operator—exerts a preservative influence and invests the economy of animals subject to its influence with an immunity which protects them from the contagion during a period not yet determined. Lymph for inoculation should be

removed as soon as possible after the slaughter of an animal not too severely affected with pleuro. It should be a very light straw colour, the paler the better, and free from all blood and frothy mucus. It is removed from the borders of the diseased portion, collected with a porcelain spoon rendered aseptic, and conveyed into vials containing pieces of worsted thread a few inches long, which, as well as the bottles, have been aseptised. One of these worsted threads is inserted, by means of a needle made for the purpose, under the skin of the tip of the tail of each animal. Inoculation is practised to an enormous extent in Australia, many stock-owners there now believing that but for this it would be impossible to rear cattle successfully.

Plevna, a town of Bulgaria, 19 miles S. of the Danube and 85 NE. of Sophia, with 14,474 inhabitants. Here in 1877 Osman Pasha, the Turkish general, after defeating the Russians in several engagements, entrenched himself against their reinforced and superior numbers early in September, and repulsed their endeavours to take the place by storm; but, after making an unsuccessful attempt to cut his way through the investing Russian army, he was compelled, provisions and ammunition running short, to capitulate (10th December) with 42,000 men and 77 guns. The siege cost the Russians 55,000 men, the Roumanians 10,000, the Turks 30,000. See W. V. Herbert, *The Defence of Plevna* (1895).

Pleximeter. See Percussion.

Pleyel, Ignaz Joseph, born 1st June 1757 at Ruppertsthal, near Vienna, studied under Haydn and in Italy, and in 1783 was made Kapellmeister of Strasburg Cathedral. In 1791 he visited London, and he harmonised many of the melodies for Thomson's *Collection of Scottish Songs*. At Strasburg, during the French Revolution, he barely escaped with his life as a royalist. In 1795 he opened a large music shop in Paris, and in 1807 joined thereto a pianoforte manufactory. He died in Paris, 14th November 1831. His compositions consisted of quartets, concertas, and sonatas.

Plica Polonica is the name given to a disease of the scalp, in which the hairs become matted together by an adhesive and often fetid secretion, and which is especially prevalent in Poland, although it occasionally occurs in other countries. The hair is found, on microscopic investigation, to be infested with a fungus of the genus Trichophyton. The only treatment that is beneficial is the removal of the hair, and strict attention to cleanliness; but, as it is popularly believed in Poland that this affection affords a security from all other sickness and misfortune, it is often difficult to persuade patients to have recourse to these means.

Plimsoll, Samuel, 'the sailors' friend,' was born at Bristol on 10th February 1824. In his seventeenth year he became clerk in a Sheffield brewery, and rose to a position of trust in the firm. In 1854 he started business on his own account, in the coal trade, in London. Shortly afterwards he began to interest himself in the sailors of the mercantile marine, and the dangers to which they were exposed. He accumulated a mass of facts proving that the gravest evils resulted from the wilful employment of unseaworthy ships, from overloading them, and under-manning them, from bad stowage, and from over-insurance; unscrupulous owners insured rotten or 'coffin' ships at a value greatly exceeding their real value, and sent them to sea, hoping they would founder, by which means they would make bigger profits than they could make by legitimate carrying of merchandise. Failing to induce parliament to take legislative steps to put an end to these evils, Mr Plimsoll himself entered parliament, for Derby, in 1868; but it was not until he had published *Our Seamen* (1873) and had made an appeal to the general public that he succeeded in getting passed the Merchant Shipping Act in 1876, to supersede temporary measures passed during three preceding sessions. By this act the Board of Trade was empowered to detain, either for survey or permanently, any vessel deemed unsafe, either on account of defective hull, machinery, or equipments, or improper loading, or overloading; a penalty not exceeding £300 was incurred by any owner who should ship a cargo of grain in bulk exceeding two-thirds of the entire cargo, grain in bulk being especially liable to shift on the voyage; the amount of timber that might be carried as deck cargo was defined, and enforced by penalties; finally, every owner was ordered to mark (often called the 'Plimsoll Mark') upon the sides of his ships, amidships, a circular disc, 12 inches in diameter, with a horizontal line 18 inches long drawn through its centre, this line and the centre of the disc to mark the maximum load-line—i.e. the line down to which the vessel might be loaded, in salt water. Failure to comply with this last regulation exposed the owner to a fine not exceeding £100 for each offence. In 1890 this act was amended, the fixing of the load-line being taken out of the owner's discretion and made a duty of the Board of Trade. Mr Plimsoll retired from parliamentary life in 1880. But he did not slacken his efforts to make the sailors' calling safer: in 1890 he published a work on *Cattle-ships*, exposing the cruelties and great dangers connected with the shipping of live cattle across the ocean to British ports. He died 3d June 1898. See Japp, *Good Men and True* (1890).

Plinlimmon, or Plynlimmon, a large mountain-mass (2469 feet) of Wales with three summits, on the boundary between Montgomery and Cardigan, 10 miles W. of Llanidloes. The name is said to be a corruption of a Celtic word signifying Five Rivers, five rivers having their sources on its slopes; one is the Severn, another the Wye.

Plinth, the square member at the bottom of the base of a Column (q.v.). Also the plain projecting band forming a base of a wall.

Pliny (Gaius Plinius Secundus), called the Elder, to distinguish him from his nephew, came of a North Italian stock possessing estates at Novum Comum (*Como*), where he was born 23 A.D. He claimed to be a compatriot of Catullus, but the reference is too vague to warrant the assumption that their common birthplace was Verona. His education was carried on in Rome, under every advantage of wealth and family connection, till, when about twenty-three years old, he entered the army, serving on the staff of L. Pomponius Secundus, then conducting a campaign in Germany. He became colonel of his regiment (a cavalry one), and while attentive enough to his military duties to make a special study of the throwing of missiles from horseback, on which he wrote a treatise (*De Jaculatione Equestri*), and to compile a history (afterwards published in twenty books) of the Germanic wars, he gratified his thirst for miscellaneous knowledge by a series of scientific tours, investigating the region between the Ems, the Elbe, and the Weser, and the sources of the Danube. Returning to Rome in 52 with Pomponius, he studied for the bar, at which he practised just long enough to satisfy himself that his aptitudes were not of the forensic order. Accordingly he withdrew to his native Como, and there, during the greater part of Nero's reign, devoted himself to reading and authorship encyclopædic in their range. Apparently for the guidance of his nephew he wrote in three books his *Studiosus*, a treatise defining the culture necessary

for the orator before entering on his career, and also for his nephew the grammatical work, *Dubius Sermo*, in eight books. About the close of Nero's life he was appointed procurator (collector of the imperial revenues) in Spain, where in 71 he heard of his brother-in-law's death, by which he became guardian of his sister's son, Pliny the Younger, whom, on his return to Rome two years after, he adopted. Vespasian, by this time emperor, whom he had known in the German campaign, was henceforth his most intimate friend, but court favour did not wean him from study, and so we find him bringing down to his own time, in thirty-one books, the history of Rome, by Aufidius Bassus. A model student, amid metropolitan distraction, he began work by candle-light, in autumn before the day was spent, and in winter by 1 or 2 A.M. Ere dawn he would wait on the emperor and discharge the imperial commissions imposed on him, after which he returned home once more to his books. A slight repast intervening, he resumed work, in summer lying in the sunshine while he took notes or extracts from what was read to him. True to his maxim that no book was so bad but some information might be got from it, he seized every opportunity of jotting down all that interested him either as reader or auditor. A cold bath, followed by a slender meal and a brief siesta, preceded the next spell of work, at which he continued till *cena*, the Roman dinner, at 3 P.M. Even then he listened to the reading of some book, on which he commented. Such was his life when at court; but at his country seat his studies were uninterrupted—an attendant reading to him even in the bath, or writing to his dictation while he was under the *masseur* or anointer (*aliptas*). On his journeys by land or water his secretary with book and tablets was always at hand. By this lifelong application he amassed materials enough to fill the 160 volumes of manuscript written very small on both sides which, after using them for his *Historia Naturalis* (published 77), he bequeathed to his nephew. His life, uneventful and studious, was quite dramatic in its ending. In 79 he was in command of the Roman fleet stationed off Misenum when the great eruption of Vesuvius was at its height. Eager to witness the phenomenon as closely as possible, he landed at Stabiæ (*Castellamare*), but had not gone far when his frame, corpulent and asthmatic as his nephew tells us, succumbed to the stifling vapours rolling down the hill.

His *Historia Naturalis* alone of his many writings survives. Under that title the ancients classified everything of natural or non-artificial origin—not only botany, zoology, and mineralogy, but geography, meteorology, and astronomy. Pliny, however, extends even this elastic definition, and adds to his work by digressions on human inventions and institutions, devoting two books to a very valuable, if misplaced, history of fine art. He dedicates the whole to Titus, in a turgid, ill-composed epistle, the low literary level of which is maintained throughout. Nor is his inartistic, sometimes obscure, style redeemed by much scientific faculty in handling his theme. He did not pretend to original research, but the philosophical method which sometimes distinguishes the mere compiler is equally foreign to his pages. His observations, made at second-hand, are presented with no discrimination between the true and the manifestly false, between the probable and the simply marvellous. He can even be convicted of having misunderstood the authorities on whom he relies. But with every deduction made from it as to matter and form, his compilation is a praiseworthy monument of reading at once extensive and minute, and supplies us with information on an immense variety of subjects as to which, but for him, we should have remained in the dark.

The most convenient text for the student is that of Jan and Mayhoff (6 vols. Leip. 1857–75), which embodies the best results of the recensions by Sillig and Detlefsen. The *Chrestomathia Pliniana* (Berlin, 1857) of the great archæologist Urlichs is particularly valuable for its comments on fine art; while of translations the soundest and most readable is that of Littré, in French, published along with the original Latin (Paris, 1848–50).

Pliny (Gaius Plinius Cæcilius Secundus), the Younger, was born at Novum Comum, 62 A.D. His education, after his tenth year, when his father died, was conducted under the eye of his mother, Plinia, of his tutor Virginius Rufus, of whose worth, intellectual and moral, he has left a beautiful memorial, and of his uncle who adopted him. He early displayed high literary aptitude, wrote a Greek tragedy in his fourteenth year, and made such progress under Quintilian that, like his friend Tacitus, he became noted as one of the most accomplished men of his time. His proficiency as an orator enabled him, when not more than eighteen, to plead in the Forum, and brought him much practice, not only at the Centumviral bar, chiefly in will-cases, but also before the senate. Official appointments came to him in quick succession. Then, still young, he served as military tribune in Syria, where he frequented the schools of the Stoic Euphrates, and of Artemidorus; at twenty-five, the earliest possible age, he was *quæstor Cæsaris*, then prætor, and afterwards consul in 100 A.D., in which year he wrote his laboured panegyric of the Emperor Trajan. In 103 he became proprætor of the Provincia Pontica, but vacated the post in two years, and, among other offices, held that of curator of the Tiber, chiefly for the prevention of floods. He married twice; his second wife, Calpurnia, granddaughter of Calpurnius Fabatus, is fondly referred to in one of his most charming letters for the many gifts and accomplishments with which she sweetened his rather invalid life. He died without issue, but in what year is unknown.

It is to his letters that Pliny owes his assured place in literature as one of the masters of the epistolary style. An avowed imitator of Cicero, he has caught much of the charm of his model, while his Latinity is hardly, if at all, inferior in purity and ease. His meaning, though never obscure, is generally fuller than his expression, and, reading between the lines, we discern the features of a truly lovable man, quite aware of his strong as of his weak points, much given to hospitality, and always pleased to help a less favoured brother, such as Suetonius or Martial. We derive from him not a few of our distinctest impressions of the public and private life of the upper class in the 1st century; above all, it is from his correspondence with Trajan that we get our clearest knowledge of how even the most enlightened of the Romans regarded the then obscure sect of the Christians. It appears that a person acknowledging himself a Christian was liable to punishment, even to death. When under examination, however, no Christian would admit anything further than his practice of meeting with his co-religionists on an appointed day before it was light; singing a hymn to Christ as God (or 'as to a God'—*quasi deo*); and taking an oath which bound him to no crime, but never to commit theft, robbery, adultery, and malfeasance, and never to deny a deposit. Even when put to the torture, two female slaves, said to be deaconesses, confessed nothing more to Pliny, who thereupon consulted the emperor as to how he might stop the spread of what he could only call 'a depraved and extravagant superstition.' Trajan declined to lay down a general rule for dealing with the Christians; he recommended that they should

not be sought out on suspicion, but that, if accused and convicted of holding that faith, they should be punished. Accusations unsupported by an accuser were not to be received, while suspected cases were to have an opportunity of clearing themselves by offering prayers to the Roman gods (*diis nostris*).

Keil's text of the *Epistles* and *Panegyricus* (Leip. 1853) is the best, while a useful selection with a good commentary has been published by Church and Brodribb (1871). Melmoth's translation (1746) is free and eminently readable; Orrery's, of the *Epistles* (1751), is still esteemed.

Pliocene System. Strata belonging to this system are restricted in Britain to a limited area in Essex, Suffolk, and Norfolk; but a few isolated patches occur also in Cornwall and Kent. They consist of irregular lenticular beds of sands and shelly gravels, &c., which never occur altogether in one place. The whole series probably does not exceed 120 feet in thickness, and comprises the following groups arranged in descending order:

Cromer Forest-bed: fresh-water or estuarine silts, clays, and sands, with layers of peat; 10 to 70 feet thick. The fossils are land and fresh-water molluscs, many land-plants, and numerous mammalian remains.

Chillesford Beds: sands and clays; 6 to 16 feet thick; contain marine shells, some two-thirds of which are existing Arctic species.

Norwich Crag: fluvio-marine gravel, sand, and loam; 5 to 10 feet thick. Fossils, chiefly marine molluscs; several land and fresh-water shells; and numerous mammalian remains—hence the name of 'mammaliferous crag' sometimes applied to this group. Of the shells 93 per cent. are living species—14·6 per cent. being northern forms.

Red Crag: red ferruginous shelly sand, 25 feet thick, but local and inconstant. About 90 per cent. of the numerous shells occurring in this deposit are existing species—10·7 per cent. being northern forms.

Lenham Beds: sands, &c., occupying 'pipes' or hollows in the chalk of the North Downs, some 600 feet above the sea.

St Erth Beds: clays and gravels, near St Erth, Cornwall; many shells, about 40 per cent. being of extinct species.

White or Coralline Crag: shelly sands and clays; fossils abundant; 84 per cent. of the shells are living species, and of these 5 per cent. are northern forms. Polyzoa (popularly called *corals*) are numerous, hence the name sometimes applied to this group.

On the Continent Pliocene marine deposits are met with in various countries, usually in maritime regions, as at Antwerp and in the west of France in the Cotentin, Morbihan, and Aquitaine. But it is in the Mediterranean basin that this system attains its greatest development. Thus, at various points along the foot of the Alps in North Italy Pliocene beds appear, and they likewise occur along both sides of the Apennines, forming the sub-Apennine formation; while in Sicily they attain a thickness of 2000 feet. In middle Europe the most important Pliocene strata are the fresh-water beds of the Mayence basin, and the fresh and brackish water beds of the Tertiary basin of Vienna. The calcareous tufas of France and Italy belonging to this system are notable for their plant-remains.

Life of the Period.—The flora of Pliocene times indicates a more temperate climate than that of the preceding Miocene. Many Miocene forms still lived in Europe, but the palms and other characteristic Miocene plants had disappeared. Ivy, platanus, liquidambar, various maples, many walnut trees, elms, hornbeams, magnolia, tulip-tree, Canary laurel, oleander, vine, glyptostrobus, sassafras, and others ranged from Tuscany to the heart of France—such plants as beech, poplar, lime, oak, sassafras, maples, bamboos, vines, &c. growing amongst the mountains of Cantal. The general character of the flora recalls the floras of distant regions—North America, the Canary Islands, eastern Asia, and Japan. The abundant evergreen plants of the period seem to have grown chiefly on the low grounds; at higher elevations pines and deciduous trees were the prevailing forms. The flora of the Norwich Crag shows that towards the close of the period the British area was clothed with a vegetation somewhat similar to that of the present. The molluscan fauna includes an increasing number of living species. In the lower groups of the system the general facies of the shells is southern, but in the upper groups the southern types decrease in importance and are gradually replaced by temperate and northern forms. Amongst land animals we find several survivors from earlier times, such as Dinotherium and Mastodon, with which co-existed many other pachyderms—elephants, rhinoceroses, hippopotamuses, and tapirs. Herbivorous quadrupeds also abounded—horses, giraffes, and various cervine and bovine forms. Carnivores (panthers, bears, wolves, &c.) were well represented, and apes and monkeys also formed a marked portion of the fauna. The Pliocene beds of Pikermi in Attica, and of India (Siwalik group), have yielded a large number of extinct and living types. At Pikermi occur the remains of many ruminants, amongst which are species of giraffe, Helladotherium, and various cervine and bovine forms, together with Mastodon, rhinoceros, Dinotherium, hyæna, and others. The Siwalik beds contain Hyænarctos, Machairodus, and other Miocene forms, and Sivatherium and Bramatherium, gigantic four-horned animals allied to antelopes. With these are associated many living genera, such as Felis, Hyæna, Canis, Bos, Bison, Capra, Ovis, &c. It may be noted that from the Pliocene of the Upper Missouri region of North America remains of an abundant mammalian fauna have also been obtained—a fauna which had a strikingly oriental aspect.

In Pliocene times the Mediterranean covered many tracts which are now dry land. The valley of the Po then formed a great arm of the sea which penetrated into the mountain-valleys of the Alps, while Italy and Sicily were largely submerged. Considerable tracts in the maritime districts of southern and western France were likewise under water. The sea also overflowed some part of the south of England (Cornwall and Kent) and encroached upon the low grounds of Belgium and East Anglia. The long arms of the sea, which in the Miocene period had stretched from the Mediterranean through France into Switzerland and the valley of the Rhine, had vanished, while fresh-water and saline lakes occupied part of the area in Austro-Hungary which had been more or less open sea in Miocene times. Much of south-eastern Europe, however, continued submerged—the sea extending through the Aralo-Caspian depression into Asia. One of the most notable events of the Pliocene was the birth of Etna, Vesuvius, and the now extinct volcanoes of Central Italy. In early Pliocene times the climate was mild and genial, but the conditions became less so during the closing stages of the period. This change is evidenced particularly by the increasing number of northern molluscs and the occurrence of ice-floated erratics in the English Pliocene.

Pliosaurus. See Plesiosaurus.

Plock (Ger. *Plozk*), a town of Russian Poland, on the right bank of the Vistula, 60 miles NW. of Warsaw. Its principal building is the cathedral, built in the 11th century. One of the oldest towns in Poland, Plock was the capital of ancient Masovia, and was severely ravaged by the heathen Prussians, the Lithuanians, and the Swedes. Pop. (1895) 20,660, including many Jews.

Plojeshti, or Ploesci, a town of Roumania, 37 miles by rail N. of Bucharest, with petroleum-refineries and a large trade in wool. Pop. 33,691.

Plombières, a spa in the French department of Vosges, 14 miles S. of Epinal, sprang into fashion through the favour of Napoleon III., though the virtues of its waters were known ever

since the times of the Romans. There are nearly thirty springs, ranging in temperature from 66° to 150° F.; their waters are helpful against skin diseases, gout, rheumatism, dyspepsia, female complaints, &c. A handsome casino was opened in 1876, and there are picturesque walks and a park in the valley in which the village stands. Pop. 1971.

Plotinus, the most original and important philosopher of the Neoplatonic school, was born at Lycopolis in Egypt in 205 A.D., and studied philosophy under Ammonius Saccas. In 242 he joined Gordianus' expedition to Persia, in order to study the philosophy of India and Persia; but the emperor being murdered in Mesopotamia, he returned hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended not only by crowds of eager youths, but men and women of the highest circles flocked to hear him. Not only Neopythagorean and Neoplatonic wisdom, but asceticism and the charm of a purely contemplative life were the themes on which he, in ever new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impression his earnestness made upon his hearers that some of them really gave up their fortune to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. Sixty years old, he thought of realising Plato's 'Republic,' by founding an aristocratical and communistic commonwealth; and the Emperor Gallienus was ready to grant a site in Campania for his 'Platonopolis;' but he died near Minturnæ in 270. Although he began to write very late in life, he yet left fifty-four books of very different size and contents to the editorial care of his pupil Porphyry, who arranged them in six principal divisions, each subdivided again into nine books or *Enneads*.

Plotinus' system was based chiefly on Plato's, combined with Neopythagoreanism and the oriental theory of Emanation—i.e. the constant transmission of powers from the Absolute to the Creation, through several agencies, the first of which is 'Pure Intelligence,' whence flows the 'Soul of the World,' whence, again, the souls of 'men' and 'animals,' and finally 'matter' itself. Men thus belong to two worlds, that of the senses and that of Pure Intelligence. It depends upon ourselves, however, to which of the two worlds we direct our thoughts most and belong to finally. The ordinary virtues, as justice, moderation, valour, and the like, are only the beginning and very first preparation for our elevation into the spiritual realm; purification is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation is the nearest approach to the goal. The higher our soul rises in this sphere of intellect, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and the ecstasy which pervades it. These are a few snatches of Plotinus' philosophical rhapsodies, to which may be added his mysterious belief in a kind of metempsychosis, by which souls not sufficiently purified during life return after death, and inhabit, according to their bent, men, animals, and even plants. He further held somewhat fantastic views as to gods and demons, and professed faith in astrology and magic. His was the last attempt by the ancient world to solve the great problems not by ratiocination, but through introspective mysticism; and his mode of thought had very unmistakable influence on early Christian philosophy, modern theosophy, and various German idealistic systems.

See NEOPLATONISM and works there cited, and works on Plotinus by Kirchner (1854), Brenning (1864), and Kleist (1884).

Plots must be distinguished on the one hand from Assassinations (q.v.) and on the other from Rebellions (q.v.). They involve the elements of secrecy and conspiracy, but have not always political assassination for their object, nor do those who carry them through, or attempt to do so, put arms in the hands of a great number of men. The subjoined list only professes to give a selection of the more noteworthy plots of history, intended to supplement the lists given under ASSASSINATION and REBELLION. Details of most of them will be found under separate articles.

Catiline's Conspiracy, 63 B.C.
Quirini-Tiepolo in Venice, 1310.
Marino Falieri's Plot in Venice, 1355.
Plot of Fieschi against Andrea Doria at Genoa, 1547.
Raid of Ruthven in Scotland, 1582.

Abduction of Alexander of Bulgaria, 1886.

Plough. The first in order and importance of agricultural operations is the breaking up of the soil, and the implement employed most largely for this purpose is the *plough*. The general form of the plough is known to every one, and to the unobservant eye it appears to be a very simple and even primitive tool; nevertheless, much mechanical skill and ingenuity have been expended in perfectly adapting it to its work. It is a combination of instruments (fig. 1) fastened to a beam,

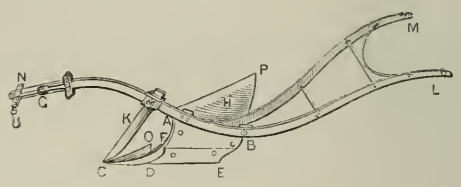

Fig. 1.

GBL; the *coulter*, K, is an iron knife-blade, for cutting the sod vertically; the *share*, CFD, which is merely a socket fitted on and not fastened to the body of the plough, has a sharp point, C, and a projecting horizontal edge, CO, on its right-hand side, its part of the work being to separate the under surface of the sod from the subsoil; by means of the *mould-board*, H, the slice, now wholly separated from the firm ground, is raised up and turned over by the forward motion of the plough;

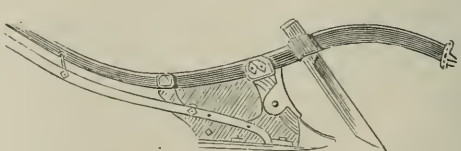

Fig. 2.

and the *stilts*, or handles, one of which, BL, is a continuation of the beam, the other, M, being fastened partly to the former by rods, and partly to the lower portion of the framework (fig. 2, which also shows the point of the plough with the share

removed), are for the purpose of guiding the implement. The front part of the beam is formed with an upward curve; at its extremity is placed the *bridle*, N, to which the horses are attached by means of swing-trees and chains or traces, and the object of which is to enable the workman to elevate or depress the line of draught, or move it to the right hand or the left, as may be found necessary. The left sides of the coulter, share, and framework ADEB should evidently be in the same vertical plane. The form of the mould-board is of the utmost importance, and has chiefly attracted the attention of agricultural machinists since the time when improvements on the plough were first projected. Its office being to raise and turn the sod, it is necessary that the surface should slope upwards and outwards from the front, so as to apply a pressure in both directions, and, accordingly, the surface is so shaped that from the point of the share, where it is horizontal, it gradually curves upwards, till, at the extremity, P, it inclines over away from the body of the plough. The gradual change produced on the position of the furrow-slice is seen in fig. 3, where ABCD on the left-hand side

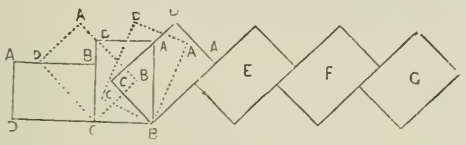

Fig. 3.

represents the slice untouched by the plough, AD being the line of section by the coulter, DC by the share, BC the open side from which the previous furrow (E) to the right hand side has been separated, and the four successive rectangles, ABCD to the right, illustrate the successive changes of position of the furrow as the mould-board is pushed forward under and on its left side, till it is finally left, as represented in ABCD, on the right hand; E, F, G are furrows which have previously been laid in their proper position. The modern plough is wholly formed of iron, and in nearly all the English and several of the Scotch and Irish made ploughs wheels are attached at or near the front end of the beam, a contrivance which renders the implement more steady in its motion, more easily managed, and capable of doing better work in the hands of an inferior workman. The usual dimensions of the furrow-slice in lea or hay-stubble are 8 or 9 inches in breadth by 6 in depth, and in land for green crop 10 or 11 inches in breadth, and 7 to 9 in depth. Shallower ploughing is not unfrequently adopted, especially on thin soils, and in various parts of England. Nor is it uncommon to plough stubble-land 10 inches or more in depth.

Other kinds of ploughs are used for special purposes, such as *trench-ploughs*, which are made on the same principle as the common plough, but larger and stronger, so as to bring up a portion of the subsoil to the surface; *subsoil ploughs*, some patterns of which have no mould-board, and merely stir and break up the subsoil, thus facilitating drainage; *double mould-board ploughs*, which are merely common ploughs with a mould-board on each side, and are employed for drilling turnip or potato land, for water-furrowing, and for earthing up potatoes; *turn-wrest ploughs*, which have the mould-board so arranged that in going in both directions the furrow is turned to the side; American *Chill ploughs*, which are exceptionally light in draught, go over the ground rapidly, and break up the surface soil more finely than the ordinary plough; the *double-furrow plough*, which turns two furrows at one operation, and which, although used on many farms, has not become so popular as was at one time expected. Of each of these ploughs there are many varieties, each maker having generally some peculiar views regarding the form and proportion of some parts of the instrument. For those who wish to study minutely the best form of plough it will be necessary to consult works on agriculture and agricultural implements.

The operation of ploughing can only be briefly referred to. Wherever the soil has been efficiently drained the ridges can be made wider and ploughed on the flat, high ridges being no longer necessary for carrying off the water. It is found in practice that the fewer the open furrows the better, particularly when the land is intended for a grain crop which is to be sown by drill or broadcast with machinery, and when the crop is to be cut with a reaping-machine, as is now almost universally the case. It is curious to notice how one improvement in farm practice leads on to another. The most common mode of ploughing with horses is now simply by casting the soil two ridges in and the next two out, beginning always with the two ridges where last time was left the open furrow.

The process of feering or commencing a ridge differs according to the state of the land to be turned over. If there exists an old furrow or hollow, as is generally the case in lea, two shallow furrows are turned, the one against the other, and so on; along each side of this commencement the plough moves, adding furrow after furrow, and increasing in depth until the third or fourth round is reached. This constitutes what is technically called the gathering system. In newly-cleaned land, or where a hollow does not appear to turn the first furrows into, two furrows are thrown out and then turned lightly in. The most common system, however, is what is known as *casting* or *cleaving*. That is, after one feering is accomplished, another is made at the other side of the ridge, and furrow after furrow is turned towards the inside of each of these feerings until the whole ridge is ploughed, and then in the centre is formed the *finish* or *mids*—a furrow or trench into which the feering is turned the next time the land is ploughed.

The plough is one of the most ancient of implements, and is mentioned in the Old Testament at a very early period, iron shares being also incidentally noticed more than seven centuries B.C. Dr E. B. Tylor has in his *Anthropology* clearly shown how the plough arose by gradual development out of the hoe, and that out of the pick or hatchet.

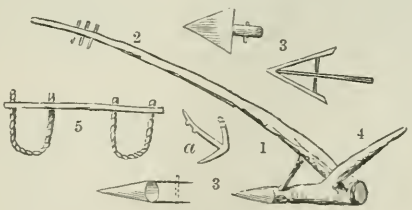

Fig. 4.

1, Plough still used in Asia Minor; 2, its pole, where the oxen are attached; 3, shares of various forms; 4, the tail or handle; 5, the yoke; *a*, early Greek plough.

The fields of Sweden were formerly tilled with the 'hack,' of which specimens were still seen in the 19th century. The hack was simply a 'stake of spruce-fir with a bough sticking out at the lower end cut short and pointed.' This implement was gradually made heavier, and dragged by men through the ground, so as to make a simple furrow. Next it 'was made in two pieces, with

a handle for the ploughman and a pole for the men to drag by, the share was shod with an iron point, and at last a pair of cows or mares were yoked on instead of the men.' The development of the Egyptian plough was similar. The ancient Egyptian plough was wholly of wood, and in some instances consisted of little more than a pointed stick, which was forced into the ground as it was drawn forward; though there seems to have been ploughs with handles, and with metal socks. The Aryan peoples took pride in their being the ploughing (*arare;* see AGRICULTURE, Vol. I. p. 98) peoples. The earliest form of the Greek plough, the *autoguon* (fig. 4, *a*), is an example of this; it was merely the trunk of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the *pelton*, in use among the Greeks, was not substantially different from the modern form in use in some parts of Asia Minor (fig. 4). The ancient Egyptian plough in one of its early stages is represented in fig. 5. The Romans, an essentially practical nation, largely improved on the plough, adding to it the coulter and mould-board, and occasionally attaching wheels to the beam to prevent the share from going too deep into the earth (fig. 6). The plough was almost unknown among the American aborigines, though Prescott describes a mode of ploughing practised among the Peruvians, which consisted in the dragging forward a sharp-pointed stake by six or eight men, its sharp point, which was in front, being kept down in the ground by the pressure of the foot of another man who directed it. The ancient heavy plough dragged by eight oxen was still in use in Aberdeenshire well into the 18th century. In Britain the most important amendments on the plough are not two centuries old, and some of them were doubtless borrowed from the careful agriculture of Holland. England took the lead in improvement, followed some time later by Scotland, in which the chief improvers were James Small (the inventor of the Scotch *swing* plough), Wilkie, Gray, and Sellar. In England the improvers have chiefly been Ransome of Ipswich (the patentee in 1785 of the cast-iron share), Howard of Bedford, Hornsby of Grantham, and Busby of Bedale, the last of whom gained a medal for his mould-boards at the Great Exhibition of 1851. Ransome's wheel-plough has long finely-made mould-boards, rather short broad shares, straight coulters, and with the two wheels on level land can almost move unattended. Ancient types, however, still survive; the East Anglian plough has only one (wooden) stilt, and is very heavy, but makes good work. There are many specially American types of plough. In the Sulki plough wheels support the weight of the plough and of the furrow-slice, decreasing friction, and saving labour to the ploughman, who has a seat on the implement; the disadvantage is the much greater cost of this kind of plough, and the cumbrous size. The Double Michigan plough has a small paring plough on the beam in front of the other; the small plough pares off the surface and throws it into the previous furrow, and the large one completely buries it under a heavy furrow-slice. Reversible ploughs, like the Oneonta Clipper, have the share and mould-board, so that they can be easily changed from one side to the other; these are also called swivel ploughs or side-hill ploughs.

Fig. 5.

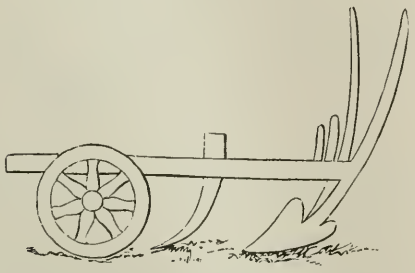

Fig. 6.

Steam-ploughing.—It has been alleged that the cultivation of the land by steam had been contemplated as far back as the 17th century. So long ago as 1618 David Ramsey and Thomas Wildgosse took out letters-patent for engines and machinery to plough the ground without the aid of oxen or horses, and the attempt has been made to show that steam was the motive power intended to be employed; but, as the first patent was taken out nearly forty years before the Marquis of Worcester described the steam-engine in his *Century of Inventions*, the grounds for such an opinion do not seem quite satisfactory. In 1769, however, after the steam-engine had been applied to other purposes, there was lodged in the Patent Office a specification for a new machine or engine, to plough, harrow, and do every other branch of husbandry, without the aid of horses. The patentee was Francis Moore; and so confident was he of the merits of his plan that he sold all his own horses, and persuaded his friends to do the same; 'because the price of that noble and useful animal will be so affected by the new invention that its value will not be one-fourth of what it is at present.' Moore, like many who followed in his wake, was much too sanguine. The truth is that even yet steam-power has only to a very small extent supplanted horse labour in the cultivation of the soil. Early English patentees were Pratt in 1810, and Heathcote in 1832. But the first steam cultivating apparatus which gave anything like satisfac-

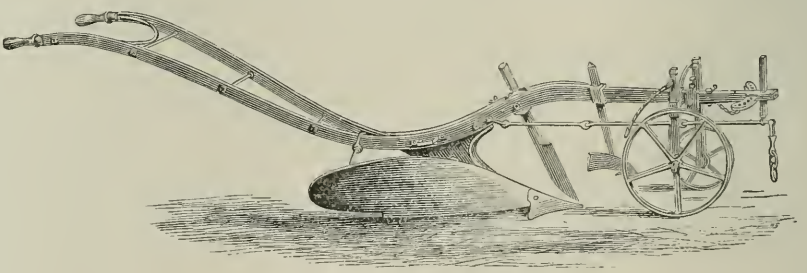

Fig. 7.—Ransome's Wheel Plough.

tory promise of success was that for which Messrs Fisken of Stamfordham, Newcastle-upon-Tyne, took out a patent in 1855. Mr Fowler of Leeds, and Messrs Howard of Bedford, and others followed with apparatuses of various patterns. The different inventions brought into notice from time to time have included plans for engines travelling over the surface of the ground, drawing ploughs or other cultivating implements along with them; engines working on tramways and drawing implements after them; engines moving along opposite headlands, and working implements between them by means of wire-ropes, and stationary engines driving implements also by means of wire-ropes. Only two of these systems got beyond the experimental stage. These are what are called the direct and round-about—the former where the pull of the implement is directly to and from the engine, or between two engines, one at each end of the furrow; and the latter where the implement is drawn at right angles. The best known of the apparatuses now in use are those made by Fowler, Howard, and Barford and Perkins, of Peterborough.

The ploughs used in the various systems are very similar in construction, some taking four and others six furrows at each time. Fowler's apparatus is shown at work in figs. 8 and 9.

It has to be noted, however, that, with all the ingenuity and capital expended on the perfecting of the appliances, steam-power has not been employed in the cultivation of the soil anything like so

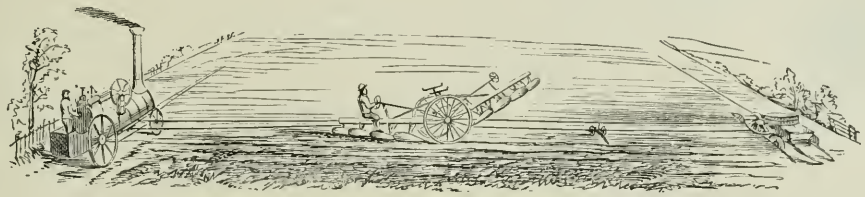

Fig. 8.—Fowler's Anchor, Engine, and Plough at work.

advantageously or extensively as was at one time expected by the advocates of the practice. The great agricultural depression following the disastrous year of 1879 gave the system its first serious check. The injury unwittingly done to large extents of land by excessively deep-ploughing—by burying the good soil and bringing bad material to the surface—also tended to discredit steam-cultivation. It has as a rule been found in practice that moderate ploughing and deep stirring are preferable to deep ploughing, and steam-power is now more largely employed in stirring and harrowing the soil than in turning it over in furrows. Upon

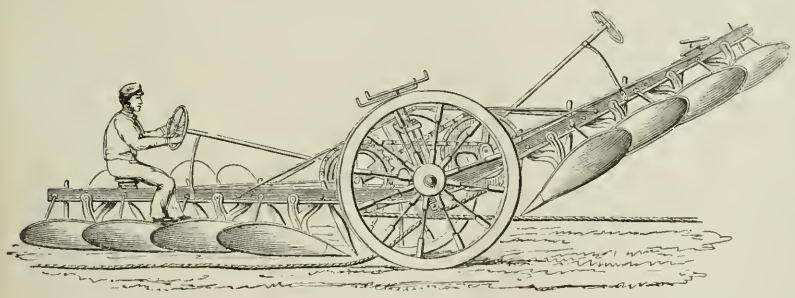

Fig. 9.—Fowler's Plough.

extensive farms, where the fields are large and conveniently shaped, steam-tillage may be pursued with excellent results, if the farmer is careful to adapt the operations to the particular character of the soil. Steam-tillage, if wisely directed, is more thorough than tillage by any other power, and the great speed attainable is also an important consideration, especially in precarious seasons, when the soil is not long in a favourable condition for being worked.

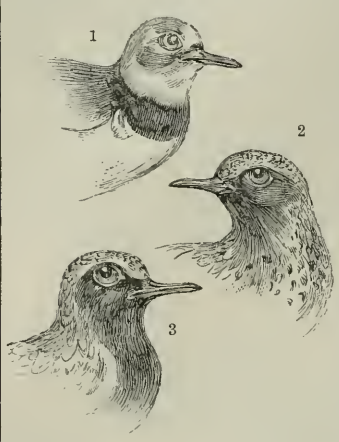
See Morton's *Cyclopædia of Agriculture* (1856); Stephens' *Book of the Farm* (new ed. by present writer, 1890); and the *Book of Farm Implements*, by Slight and Scott Burn (1858); Professor J. Scott's *Farm Engineering* (1884); and Scott Burn's *Text-book of Farm Engineering* (1885).

Ploughgate, in the law of Scotland, is an expression denoting a quantity of land of the extent of 100 acres Scots. See CARUCATE.

Plough-Monday, or PLOW-MONDAY, the Monday after Twelfth Day, and termination of the Christmas holidays, when, according to the old usage, the plough should be set to work again. On Plough-Monday ploughmen were wont to drag a plough from door to door, begging money for the usual antics and rude festivities.

Plover, a name given to numerous species of birds belonging to several genera of the family Charadriadæ. They have a straight compressed bill, but the upper jaw is slightly inflated and slightly bent at the point; the nasal groove extends about two-thirds of the length of the bill, the nostrils are longitudinally cleft near the base; the legs, which are not very long, are naked a little above the tarsal joint; with one exception there is no hind-toe; the wings are rather long and pointed, the first quill-feather is the longest. The species are numerous, and are found in every quarter of the globe; many of them are birds of passage. They chiefly frequent low, moist grounds, where they congregate in large flocks, and feed on worms, molluscs, insects, &c.; but some of them visit mountainous regions in the breeding season. They fly with great strength and rapidity, and run with much swiftness. The flesh and eggs of many of them are esteemed delicacies. A common British species is the Golden Plover (*Charadrius pluvialis*), a handsome bird, of a blackish colour, speckled with yellow at the tips and edges of the feathers; the throat, breast, and belly black in summer, whitish in winter. The golden plover is a bird of passage, visiting in summer the northern parts of Europe, of the west of Asia, and of North America, and migrating to the south in winter. It is known in most parts of Europe, and is common in many districts of Britain, breeding in the northern counties. Great

numbers frequent the sandy pastures and shores of the Hebrides and of the Orkney and Shetland Islands. It makes an artless nest, little more than a slight depression in the ground, and lays four eggs. The parent birds show great anxiety for the protection of their young, and use various stratagems to divert the attention of an enemy. The golden plover exhibits great restlessness on the approach of wet and stormy weather, whence its specific name *pluvialis*. The Ringed Plover (*Ægialitis hiaticula*), locally called Stone-hatch or Sand-lark, a much smaller bird, not so large as a song thrush, is found at almost all seasons on the shores of the British Islands, frequenting sandy and shingly flats, from which the sea retires at ebb-tide. It is often to be seen also on the banks of large rivers, and not unfrequently by lakes and ponds. It is found in most of the northern parts of Europe and Asia, and in Iceland and Greenland. It is grayish brown above, whitish beneath, with a collar of white round the neck, and below it a black—in winter a brown—collar; the head marked with black and white; a white bar on the wing. Very similar, but smaller, and with an incomplete collar, is the Kentish Plover (*Æ. cantiana*); and also similar in form and habits is the smallest of the British species, the Little Ringed Plover (*Æ. curonica*). Both of these are rare in Britain. The Gray Plover (*Squatarola helvetica*), a species somewhat larger than the golden plover, is distinguished by black axillaries, white tail-coverts, and the presence of a hind-toe. North America has a number of species of plovers, such as the Kildeer Plover (*Æ. vocifera*), abundant on the great western prairies, and not unfrequent in the Atlantic states. It utters, when approached by man, a querulous or plaintive cry, like the lapwing, the Green Plover. See DOTTEREL, and LAPWING; and for the so-called Stilt Plover, see STILT.



1, Ringed Plover; 2, Gray Plover; 3, Golden Plover.

Plover's eggs are sold in enormous quantities in London and other large towns, and command an extraordinary price, eighteen shillings a dozen or even more, being sometimes given for them, and the cost is seldom less than threepence or sixpence per egg. These are supposed all to be plover's eggs, or, really, lapwing's eggs; but doubtless the eggs of many other birds are substituted, those of the red-shank being very similar in appearance and flavour. Rook's eggs are too decidedly unlike the plover's to be put in their place. Some sea-birds' eggs are occasionally passed off under the name; and it is said that eggs outwardly unlike plover's have been skilfully painted by hand in order to deceive. Scotland, Ireland, and Holland are all laid under contribution to produce the tens of thousands of dozens of genuine plover's eggs which it is computed are annually consumed in London.

Plum (*Prunus communis* or *P. domestica*), a species of fruit-tree of the natural order Rosaceæ. The plum is so familiar as a fruit in all temperate countries as to need no description here. The Wild Plum, or Blackthorn, or Sloe (q.v.), is common in English hedgerows, thickets, and open woods, and occurs more sparingly in similar places in Scotland. It is abundant in Europe generally, and in Russia and central Asia. From the sloe all cultivated varieties of the plum are supposed to be derived, but some conjecture that *P. insititia* (Bullace, q.v.) and *P. spinosa* are the parents of some of the types of these varieties. The most reasonable probability is that the several forms of wild plum found in England and in other countries where they abound are merely varieties of one species—*P. domestica*. Other varieties of plum, besides the Sloe, Bullace, and Damson found wild in England, are the Mussel and the Wine Sour, which are used in cooking and in confectionery, and are regarded as primary varieties of the wild plum. The cultivated varieties of the plum are very numerous; there are larger and smaller kinds, but their value in the dessert is reckoned by their sweetness and flavour rather than by their size. Thus, the Green Gage, a kind with only moderate-sized fruit, is the most esteemed of all. It is the *Reine Claude* of the French, and the *Regina Claudio* of the Italians. *Magnum Bonum*, a very large white variety, though one of the handsomest, is accounted only of second-rate quality. The uses of the plum for dessert in the making of pies, tarts, preserves, and sweetmeats are familiarly known. *Prunes* are the dried fruit of certain kinds of plum. The finest of all the French prunes are made at Brignole in Provence of the varieties of plum called *Perdrigon blanc* and *Perdrigon violette*, which are hence named *Pruneaux de Brignole* or *Brignoles*. The manner of converting these plums into prunes is by drying in a slow oven. The fruit is allowed to remain on the tree till it is so ripe that a little shaking would cause it to fall. They are then carefully picked and spread out in the sun on sieves made of lath or wickerwork, till they become soft. Afterwards they are put in a spent oven, and shut up close in it for twenty-four hours, and then taken out. The oven is again heated, somewhat warmer than before, and the plums returned to it till the following day, when they are taken out and turned by slightly shaking the sieve. Again the oven is re-heated, rather warmer than before, and the fruit returned to it for twenty-four hours, and so on till the operation of drying is finished, a point which only experience can nicely determine when reached. Other kinds of prunes of inferior quality are made from the fruit of the *Petit Damas*, and from the *Quetsche*, the latter being made in Germany. From this also is distilled a kind of brandy. In Bosnia and Herzegovina nearly 50,000 tons of prunes are produced in a good season. Prunes are nutritious and laxative, and stewed in water are excellent diet in cases of costiveness, and during convalescence from fevers and inflammatory complaints. They impart their laxative quality to the water in which they have been stewed, and thus a pleasant and beneficial decoction may be prepared for those who through impairment of the digestive organs cannot eat the fruit. The plum is grown in orchards as standard and bush trees, or they are in the case of the choicer varieties trained to walls. It is not fastidious as to soil, but the finest fruit is produced on strong but well-drained loam. The superior kinds are propagated chiefly by budding and by grafting, the inferior by layers or by cuttings of the roots, the latter being a common method in rearing Damsons in some parts; but the quickest and best method of increasing all is by budding. The wood of the plum-tree is hard and fine-grained, and is used in cabinet-work, in turnery, and for making musical instruments. The Cashmere Plum (*P.*

Bokharensis), cultivated in Cashmere and Bokhara, is regarded as a distinct species. The Cherry Plum, or Myrobalan Plum (*P. cerasifera* or *Myrobalanus*), is a bush very similar to the sloe, with pendulous globular red fruit. It is a native of North America, but is often cultivated for its fruit on the continent of Europe. In Britain it seldom produces fruit. *P. maritima* is a shrub, indigenous to sandy soils on the seacoast of North America from Massachusetts to Alabama. It has a dark-purple agreeable fruit, about the size of a pigeon's egg. Other native American species are *P. chickasa*, the Chickasaw Plum, a shrub or small tree of the southern states; *P. americana*, a bushy tree ranging from Canada to Georgia; and *P. glandulosa*, of Texas, which is less than a foot high, and has crooked thorny branches.

The Cocoa Plum or Icaco of the West Indies is the fruit of *Chrysobalanus icaco*, a tree of the natural order Rosaceæ, sub-order Chrysobalaneæ. The fruit resembles a plum, has a sweet although slightly austere taste, and is eaten both raw and preserved. The fruit of *Parinarium excelsum*, another of the Chrysobalaneæ, is called Gray Plum at Sierra Leone.—The term plum is used loosely for the Date Plum (q.v.); and plum or plumb was a word once current for £100,000.

Plumage. See BIRD, and FEATHERS.

Plumbagineæ, or PLUMBAGINACEÆ, a natural order of exogenous plants, herbaceous or half-shrubby, to which belong about 160 known species, chiefly found on the seashores and in the salt marshes of temperate regions. Some are found also in elevated regions in all zones. Many have flowers of great beauty, and are therefore favourites in gardens. Some are occasionally used in medicine as tonics and astringents; others, being exceedingly acrid, as vesicants, particularly species of Plumbago. Thrift, or Sea-pink (q.v.), is the most familiar British example of the order. *Statice caroliniana*, a native of the United States, and there known by the name 'Marsh Rosemary,' is extremely bitter and astringent, and is used in domestic medicine for ulcerations of the mouth. Its most abundant principle is tannic acid, of which it contains 12·4 per cent. Along with this it gives a peculiar gum and extractive volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts. Sea-lavender (*Statice Limonium*)—an inhabitant of the coasts of England, generally, but rather rarely so, of the Scottish coasts, common, however, on the western coasts of Europe, the Mediterranean, and western Asia, appearing also on the seashore of South America and of the Carolinas—has the same qualities as the preceding.

Plumbago. See BLACK LEAD.

Plumber-work. See BUILDING, SANITATION, SEWAGE, WATER-SUPPLY.

Plume-bird, a term sometimes given to the Epimachidæ or Long-tailed Birds of Paradise (q.v.).

Plummer's Pills. See GUAIACUM.

Plumptre, EDWARD HAYES, was born in London, August 6, 1821, and educated privately and at University College, Oxford, graduating with a double first-class in 1844. The same year he was elected fellow of Brasenose College. He became chaplain at King's College, London, in 1847, and afterwards professor of New Testament Exegesis there. In 1863 he was given a prebend of St Paul's, and from 1875 to 1877 he was principal of Queen's College, Harley Street. He was select preacher at both universities, Boyle Lecturer in 1866–67, and one of the Old Testament Company for the Revision of the Bible. In 1869 he was presented to the rectory of Pluckley in Kent, which four years after he exchanged for the vicarage of Bickley, and in 1881 he was installed Dean of Wells. He received the D.D. degree from Glasgow in 1875. He died after a short illness, February 1, 1891. Of his numerous contributions to theology may here be named *King's College Sermons* (1860), his Boyle Lectures, *Christ and Christendom* (1867), *Biblical Studies* (1870), *Exposition of the Epistles to the Seven Churches of Asia* (1877), *Introduction to the New Testament* (1883), and *The Spirits in Prison* (1884), in which he spoke out eloquently his belief in the Wider Hope and an Intermediate State of Probation. He contributed Proverbs to the *Speaker's Commentary;* Matthew, Mark, Luke, Acts, and 2 Corinthians to Bishop Ellicott's *New Testament Commentary for English Readers*, as well as Isaiah, Jeremiah, and Lamentations to the same editor's *Old Testament Commentary;* Ecclesiastes, James, 1 and 2 Peter, and Jude to the *Cambridge Bible for Schools*; and 1 and 2 Timothy to Dr Schaff's *Popular Commentary on the New Testament.* Besides these, his contributions to Smith's Dictionaries and the theological and literary journals were numberless. Dean Plumptre's name is also widely known by his admirable verse translations of *Sophocles* (1865), *Æschylus* (1868), and the *Commedia* of Dante in the metres of the original (1886); as well as by several volumes of original verse, among them *Lazarus* (1864), *Master and Scholar* (1866), and *Things New and Old* (1884). His *Life and Letters of Bishop Ken* (1886) is less happy.

Plum-pudding. This national English dish is an example of the happy results of the law of evolution. The 'plumb-porridge' which delighted our ancestors has been drained and dried and squeezed into the moulds of civilisation, and few will doubt the 'survival of the fittest' among its ingredients. It is not known when the change from porridge to pudding actually took place. In *Hudibras* we find a mention of 'minced pies and plumb-porridge.' Addison in the *Tatler* speaks of both as the 'first parts of the dinner;' and in the *Spectator*, No. 269, plumb-porridge is mentioned as eaten on Christmas Day. Southey in his *Omniana*, vol. i. p. 7, quotes a recipe for plum-pudding as given in French by the Chevalier d'Arvieux, who in 1658 made a voyage in an English forty-gun ship. This pudding was directed to be boiled in meat broth, and when dished up to be covered with grated cheese. In the earlier collections of recipes we find nothing of the kind, unless a hint of plum-porridge be discerned in the mixture called *Rape*, a *posset* of 'raissins of corans' with 'swet wyne' and 'crustes of bred.' A recipe for this is given in *A Noble Boke off Cookry* (ed. Napier, p. 109), which must have been written out in the 15th century, but was then probably copied from one of a much earlier date. For a modern recipe the following may be taken: Plum-pudding—½ lb. beef suet, ½ lb. raisins, ½ lb. currants, ½ lb. sultanas, ¼ lb. mixed peel, ¼ lb. bread-crumbs, ¼ lb. flour, one lemon, ½ lb. moist sugar, four eggs, one gill of milk, one wineglass of brandy, two oz. almonds, half a nutmeg, a little salt. Chop the suet finely, stone the raisins, clean and pick the currants, blanch and chop the almonds, cut the candied peel in thin shreds. Mix all very well together. Turn into a well-greased basin, cover with a cloth, and boil for four hours, or, better, steam for twelve hours. Serve with brandy or sweet sauce.

Plumstead. See ERITH.

Plumularia, a genus of Hydrozoa (q.v.) belonging to the division Hydroidea.

Plumule. See SEED.

Pluralism, the holding of more than one office at the same time. Persons in power have often

added to their wealth and consequence by holding several appointments; but such pluralism is forbidden by the constitutional practice of many modern states. In England a minister who holds two political offices (e.g. those of First Lord of the Treasury and Chancellor of the Exchequer) receives only half the salary of the second. Pluralism in the church has been held unlawful from the earliest times, and is forbidden by many ancient councils, as Chalcedon (451 A.D.), 2d Nicæa (787 A.D.). This prohibition, however, was not regarded as absolute; canonists distinguish 'compatible' and 'incompatible' benefices or dignities. Two benefices may be incompatible in three ways—(1) if each requires residence; (2) if the duties of both fall to be discharged at one and the same time; or (3) if the revenue of either fully suffices for the becoming maintenance of the incumbent. In other cases benefices or dignities are considered compatible, and with the due dispensation, granted by the pope, may be held by the same person. In England the law of the church has been made more stringent by acts of parliament passed in 1837, 1850, and 1885. The effect of these acts seems to be that no person can now hold two benefices unless the churches are within two miles of each other and one of them is not worth more than £200 a year. A benefice of 3,000 population is not to be held along with a benefice of 500 population. In order to hold two benefices a clergyman must obtain a dispensation from the Archbishop of Canterbury, and on applying for the dispensation he must forward to his bishop a full statement of particulars in regard to the two cases. Acceptance of a second preferment, except in the cases provided for in the acts, will vacate any preferment previously held. The practice of granting livings to be held *in commendam* with a bishopric has been abolished. In Scotland it is contrary to the old Scotch statute of 1581 for a minister of the Established Church to hold two or more charges, and the rule has been regularly enforced in the case of two pastoral charges. The question has, however, sometimes arisen with reference to clergymen appointed professors before or after an appointment to a pastoral charge, in which case a resignation is now necessary of one of the offices within a certain time after the appointment. Non-established churches, in Great Britain and elsewhere, are guided by the rules of their respective constitutions. See, for England, Cripps, *Laws of the Church and Clergy;* and for Scotland, Duncan, *Paroehial Law.*

Plush (Fr. *peluche*), a variety of cloth woven like velvet, but differing from it in having a longer and more open pile. Formerly this pile was of goat's hair or worsted, but now it is largely made of silk, with a cotton backing, and sometimes the whole fabric is of silk. Silk plush is the material used for the outside of gentlemen's 'silk' hats, and is called hatter's plush. It is also worked in colonred silks for articles of ladies' attire and for covering furniture; but plush is used *par excellence* for livery knee-breeches.

Plutarch (*Ploutarchos*), a prolific writer of the Græco-Roman period, was born about 46 A.D. at Chæroneia in Bœotia, where his family was one of good standing. Nothing is known of his personal history but what may be gathered from his own writings. His higher education was commenced at Athens under the academic philosopher Ammonius in 66, the year of the Emperor Nero's progress through Greece. He paid more than one visit to Rome, the then metropolis of the world—on the first occasion in the reign of Vespasian as *chargé d'affaires* of his native town. There he enjoyed the friendship of several men of mark, such as Gaius Sossius Senecio, who was four times consul, while he devoted himself to a course of study and gave public lectures in philosophy, so that he had but little leisure left for learning the Latin language, and never attained a full knowledge of its niceties and idioms or a correct notion of Roman institutions. The story that he became Trajan's preceptor, and was raised by that emperor to the consulship is a legend of doubtful credit. Life at Rome, however, was not altogether to his taste; he preferred the quiet of his native place, and there he spent all his mature life until his death about 120, discharging the civil and religious duties which fell to his station, liberally disbursing his stores of learning, and offering himself as a sort of spiritual guide and physician of the soul to those who needed moral hygiene and desired to rule their lives by some higher standard in a corrupt and effete age, when the old faiths were dead and the objects of modern life as yet below the horizon. The extant writings of Plutarch fall into two principal classes—(*a*) his historical works, (*b*) those which are grouped under the general head of *Opera Moralia* (*ἠθικά*). To the former belong his *Parallel Lives*—the work by which he is best known. These contain a gallery of portraits of the great characters of the ages preceding his own. They were published in successive books, each pair forming one book (*biblion*), a Greek and Roman, with some resemblance between their respective careers, being chosen for the subject of each. The forty-six extant *Lives* were contained in twenty-two books, probably in the following sequence (that in which they are usually arranged being purely arbitrary): (2) *Sertorius—Eumenes*, (3) *Cimon—Lucullus*, (4) *Lysander—Sulla*, (5) *Demosthenes—Cicero*, (6) *Agis* and *Cleomenes—Graechi*, (7) *Pelopidas—Marcellus*, (8) *Phocion—Cato mi.*, (9) *Aristides—Cato ma.*, (10) *Pericles—Fabius Maximus*, (11) *Nicias—Crassus*, (12) *Dion—Brutus*, (13) *Timoleon—Æmilius Paulus*, (14) *Philopœmen—Titus Flaminius*, (15) *Themistocles—Camillus*, (16) *Alexander—Cæsar*, (17) *Agesilaus—Pompeius*, (18) *Pyrrhus—Marius*, (19) *Solon—Valerius Publicola*, (20) *Demetrius—Antonius*, (21) *Alcibiades—Coriolanus*, (22) *Theseus—Romulus*, (23) *Lycurgus—Numa*. The first series, which includes (2) to (9), was written at the suggestion of some personal friends. The biographies in this series partake more of a historical than of an ethical character. The second, (10) to (19), was composed for the writer's own satisfaction and moral improvement; the third, (20) and (21), professed to teach virtue by painting its opposite; the fourth, (22) and (23), dealt with prehistoric characters. The single biographies of *Aratus*, *Artaxerxes*, *Galba*, and *Otho* do not come under the category of *Parallel Lives*. The sequels which comes after most of the Lives, giving a detailed comparison (*synkrisis*) of each warrior, statesman, legislator, or hero, as the case may be, and of the exact points of resemblance between them, hardly accord with the design of Plutarch, and are therefore regarded as spurious by some critics.

Plutarch's *Biographies* are not merely popular compilations, but monuments of great literary value for the precious materials which they contain, based as they are upon lost records. The author adheres throughout to his professed purpose—viz. portraiture of character; he either omits or briefly touches upon the most famous actions or events which distinguish the career of each subject of his biography, holding that these do not show a man's virtues or failings so well as some trifling incident, word, or jest. 'C'est la verité morale,' says Gréard, 'non la verité historique, qu'il poursuit; l'une n'est pour lui que

le moyen, l'autre est le but.' For this reason the *Parallel Lives* are and will remain the book of all ages, for no book of classical antiquity has had more influence upon the leading men of the world, so that Plutarch may almost be called the interpreter of Greece and Rome to modern Europe. They form indeed a complement to the other and less known half of his writings—the *Morals*—a collection of short treatises, sixty or more (though certainly not all from Plutarch's hand), upon various subjects—*Ethics*, *Politics*, *History*, *Health*, *Facetiæ*, *Love-stories*, and *Philosophy*. The last comprise dissertations *On the nature of the unseen world and spiritual beings*, *On the creation and government of the Universe*, *On the human soul*, and similar speculations, classed by the ancients under the head of *Theosophy*. 'The treatise upon *Isis and Osiris* in this series,' says its most recent translator, Mr C. W. King, 'is the only complete account of the religion of Egypt that has come down to us—written too by one who had been initiated in its deepest mysteries. The three treatises upon the *Oracles* also are of the highest value, and that on *Superstition* is one of the most eloquent and closely reasoned compositions of antiquity.' Some of the essays, especially those *On Brotherly Love*, *On gradual advance in virtue*, *On the benefit to be got out of enemies*, breathe quite a Christian spirit, although the writer probably never heard of Christianity or its divine founder. One of the most interesting is that *On the apparent delays in divine justice;* another, *On the conduct proper to young men at Lectures*, which is partly moral, partly social in its tone. The nine books of his *Symposiaca* or Table-talk on a variety of topics exhibit him in the light of the most amiable and genial of boon companions, who appreciated good conversation; while his dialogue *Gryllus* reveals a remarkable sense of humour.

Though not a profound thinker, Plutarch was a man of rare gifts, and occupies quite a unique place in literature as the encyclopædist of antiquity. He was not master of any science, but whatever was noticeable in natural, moral, or metaphysical science did not come amiss to him, and he had a universal sympathy with genius and nobility of character. As a moralist he is, as Professor Mahaffy well describes him, the spokesman of the better life that still survived in the Greek world in the 'Martinmas summer' of its history; not the exponent of any system, and only occasionally an opponent, as in the *Dialogue against Colotes*, the disciple of Epicurus, and that *Against the Stoic first conceptions*, but a man of practical views and sober judgment, a chief example of the illumination of the intellect by the power of morals. His kindly sympathy and tender-heartedness, a leading feature in his character, is well shown in his *Consolation addressed to Apollonius on the early death of his son*, and the beautiful *Letter to his wife on the death of their only daughter*. As a stylist he is picturesque, realistic and varied; his chief fault is a tendency to diffuseness and redundancy of expression. He does not, like his contemporary Lucian, affect the Attic purity and clearness of diction, and he is too fond of crowding his sentences; but occasionally he rises into eloquence, and he is almost always happy in the novelty of his illustrations and similes and the point of his anecdotes.

The best editions of Plutarch's entire works are those of J. J. Reiske (12 vols. 1774–79) and Dübner-Döhner in Didot's *Bibliotheca* (5 vols. 1846–55). The best text of the *Lives* is that of Sintenis in the Teubner series (5 vols. 1874–81); of the *Moralia*, that of D. Wyttenbach (15 vols. Oxford, 1795–1830; unfinished), and that in the Teubner series by G. N. Bernardakis (6 vols., published in 1888–95). Separate annotated editions of the *Lives* have been published by Held, Leopold, Siefert-Blass, Sintenis-Fuhr in Germany, and in England by the present writer, with elaborate commentaries (*Sulla*, *De mosthenes*, *Gracchi*, *Nicias*, *Timoleon*, and *Themistocles*) and by E. G. Hardy (*Galba* and *Otho*). There are translations of the *Lives* in English by the brothers Langhorne and by Dryden and others (the latter re-edited by A. H. Clough, 5 vols. 1874)—neither so scholar-like and correct as the French of Jacques Amyot (Paris, 1559), from which Sir Thomas North's version (1579; new ed. by Wyndham, 6 vols., 1895 *et seq.*) was made; also of the *Roman Lives* by G. Long. The best translation of the *Moralia* is that by several hands, corrected and revised by W. W. Goodwin (Boston, U.S., 1874–78).

Pluto (Gr. *Ploutōn*, from *ploutein*, 'to be rich'), originally only a surname of Hades, as the giver or possessor of riches, is, in the mythology of Greece, the third son of Cronos and Rhea, and the brother of Zeus and Poseidon. On the tripartite division of the universe he obtained the sovereignty of the under-world—the realm of darkness and ghostly shades, where he sits enthroned as a 'subterranean Zeus'—to use the expression of Homer, and rules the spirits of the dead. His dwelling-place, however, is not far from the surface of the earth. Pluto is inexorable in disposition, not to be moved either by prayers or flatteries. He is borne on a car, drawn by four black steeds, whom he guides with golden reins. His helmet makes him invisible. According to some scholars, his name of *Hades* is from *a* priv., and *idein*, 'to see;' although others, with less probability, derive Hades from *hadō* or *chadō*, 'I receive or embrace,' and translate the word the 'all-receiver.' In Homer Hades never means a place, but always a person. Moreover, it is to be noticed that the poet does not divide the realm of the shades into two separate regions. All the souls of the dead—good and bad alike—mingle together. Subsequently, however, when the ethical conception of future retribution became more widely developed, the kingdom of the dead was divided into Elysium (q.v.), the abode of the good, and Tartarus (q.v.), the place of the wicked. This change also exercised an important influence on the conception of Pluto. The ruler of the under-world not only acquired additional power and majesty, but the very idea of his character was essentially modified. He was now regarded as a beneficent deity, who held the keys of the earth in his hand, and possessed its metallic treasures (whence his new name *Pluto* or *Plutus*), and who blessed the year with fruits, for out of the darkness underground come all the riches and swelling fullness of the soil. Hence, in later times, mortals prayed to him before proceeding to dig for the wealth hidden in the bowels of the earth.

Pluto married Persephone (Proserpina), the daughter of Demeter (Ceres), after carrying her off from the plains of Enna. He assisted his brothers—according to the mythological story—in their wars against the Titans, and received from the Cyclopes, as a reward for delivering them from Tartarus, the helmet that makes him invisible, which he lent to Hermes (Mercury) in the aforesaid war, to Perseus in his combat with the Gorgons, and which ultimately came to Meriones. The Erinnyes and Charon obey his behests. He sits in judgment on every open and secret act, and is assisted by three subordinate judges, Æacus, Minos, and Rhadamanthus. At Elis alone was there a formal cult of Pluto, though in many places in Greece he was worshipped conjointly with Demeter and Korē. Among trees and flowers the cypress, boxwood, narcissus, and maidenhair were sacred to him; black rams and ewes were sacrificed to him amid the shadows of night, and his priests had their brows garlanded with cypress wreaths. In works of art he resembles his brothers Zeus and Poseidon; only his hair hangs down somewhat wildly and fiercely over his brow, and his appearance, though majestic, as becomes so

mighty a god, has something gloomy and terrible about it.—The Plutonian theory in Geology, otherwise called Vulcanist or Huttonian, was opposed to the Neptunist or Wernerian. See GEOLOGY, Vol. V. p. 148, and HUTTON; and for the Plutonic rocks, see also IGNEOUS ROCKS.

Pluviometer. See RAIN-GAUGE.

Plymouth, one of the most famous of English seaports, an ancient parliamentary, municipal, and county borough, lies in the extreme south-western corner of Devonshire, 246 miles by rail (216 by road) WSW. of London, 128 SW. of Bristol, and

53 SW. of Exeter. It occupies the northern shore of Plymouth Sound (see below), immediately at the mouth of the Plym. The remaining space between it and the Hamoaze, the estuary of the Tamar, is occupied by the sister but much smaller town of Stonehouse (q.v.), while still farther to the west, along the Hamoaze itself, stretches the third of the 'Three Towns,' Devonport (q.v.). They are all, however, so united now by continuous lines of houses that, with their respective suburbs, they have lost their individuality, and to the stranger appear one great community. The chief government establishments are at Devonport—the dockyard, gun-wharf, steam-factory, and principal barracks; while Stonehouse has its quota in the victualling yard, marine barracks, and naval hospital. Plymouth, which is more populous than the other two together, is at once the chief seat of commerce, trade, and manufacture, and within the 19th century displayed an enterprise which gives it a high place among provincial centres. The site is a very fine one. Between the two natural inlet harbours of Sutton Pool and Mill Bay stretches the bold rocky ridge of the Plymouth Hoe, the eastern end of which is occupied by a citadel built by Charles II. Northward the ground rises in a series of long hills, along which the town stretches until it passes into a suburban hill of singular attractiveness. From the Hoe there are magnificent views both seaward and landward. Here, according to tradition, the captains of the fleet which assembled to meet the Armada whiled away the time by playing a game of bowls, which was interrupted by the news of the approach of the enemy; and here stand a tercentenary memorial to the Armada heroes (1890), and a statue (1884) of Sir Francis Drake (one of Boehm's finest works). The upper portion of the lighthouse erected by Smeaton on the Eddystone (q.v.) was also rebuilt here in 1882–84. Old Plymouth is chiefly clustered round the shores of Sutton Pool—a dingy unattractive set of narrow streets; but of recent years miles of excellent thoroughfares and many handsome buildings have been erected, chief among them a noble Gothic guildhall, opened in 1874 by the Prince of Wales, Lord High Steward of the borough. The principal antiquity is the fine 15th-century church of St Andrew, Perpendicular in style, and restored in 1874–75 by Sir Gilbert Scott; Charles Church (1646–58) is a singularly good example of post-Reformation Gothic; the Roman Catholic cathedral is an effective Early English edifice (1858). The Cottonian collection of sketches by the leading continental masters is at the Proprietary Library; there is a good local museum at the Athenæum; and among the numerous charitable institutions the first place is taken by the South Devon Hospital, opened in 1884 at a cost of £40,000. The town is served by both the Great Western and London and South-Western Railways. In Mill Bay are the Great Western Docks, now the property of the former company, which are capable of taking the largest merchant-vessels. Sutton Pool, the ancient tidal harbour of Plymouth, in addition to a large general trade, is the seat of the fisheries of the port, which are very important. Manufactures, mainly chemical, are carried on—at Cattedown chiefly, but also at Mill Bay. There is a large foreign, and a very extensive coasting trade, and the port is used by lines of passenger-steamers to almost every quarter of the globe.

Though only a fishing-village at the Conquest, under the name of Sutton, Plymouth has for centuries played a leading part in the nautical life. It was the favourite port of the Black Prince; the chief Elizabethan rendezvous of Drake, Hawkins, Grenville, Raleigh, and their fellows; the final port of departure of the *Mayflower* with the Pilgrim Fathers. In the civil wars it sided with the parliament, and successfully endured a series of sieges and blockades extending over four years, sharing with Hull the honour of saving the parliamentary cause. It was also the first town to declare for William of Orange. In the great French war it rivalled Portsmouth in naval activities. Among its more distinguished natives are Sir John Hawkins, Sir Richard Hawkins, Sir Thomas Edmonds, Joseph Glanvill, R. S. Hawker, Lord Monkswell, Sir W. Snow Harris, F.R.S., W. Elford Leach, F.R.S., with Northcote, Haydon, S. Prout, Sir C. Eastlake, P.R.A., and S. Hart, the artists. It is now an important scientific centre in connection with the Marine Biological Laboratory (opened in 1888), which publishes a Journal. Plymouth was first incorporated by Henry VI. in 1439, and has since always returned two members to parliament. Pop. (1801) 43,194; (1851) 52,221; (1871) 70,091; (1881) 76,080; (1891) 87,307.

PLYMOUTH SOUND, on the south-west of Devonshire, near the entrance of the English Channel, is one of the famous roadsteads of the world. It is a deep inlet, into which the river Tamar falls from the west, and the river Plym from the east. The extreme seaward boundaries of the bay, from which the Sound, properly so called, opens, are Rame Head (mentioned in Ptolemy) and Stoke Point, not far within which a third river, the Yealm, debouches. The Sound, however, is practically bounded southward by a line drawn from Penlee to Wembury Points, and northward by the Plymouth Hoe. Within these limits its width varies from 2½ to 3 miles, while its landward depth is about 3. Immediately within Penlee Point, on the western side, is Cawsand Bay, formerly one of the chief anchorages of the port and navy, but so exposed to the south-easterly gales that it was at times very

dangerous; while if vessels anchored in the Sound itself they were open to the full fury of the south-westers. Hence Earl St Vincent pressed forward a scheme for the provision of artificial protection, and in 1812 the construction of the Plymouth Breakwater was begun, from plans prepared by Messrs Rennie and Whidby. This great national work is an insulated mole of stones, a mile in length, stretching across the middle of the Sound, 2 miles from the Hoe, and thoroughly protecting the inner anchorage. It was not completed until 1841, and cost £1,500,000 (see BREAKWATER). About half a mile from the Hoe is a little islet, originally called St Nicholas Island, but now more commonly Drake's Island. This is strongly fortified. A formidable stone fort has also been built on an artificial island immediately within the breakwater; while on either shore there are extensive forts and batteries—at Bovisand and Stamford on the east, and at Picklecombe, Maker, and Tregantle on the west. The estuary of the Plym is called the Cattewater, and is a capacious and important inner mercantile anchorage, opening from the Sound eastward, and protected by the Batten breakwater. The estuary of the Tamar is called the Hamoaze, and from the spot at which it enters the Sound between Devil's Point and Mount Edgecumbe to Saltash is nearly 4 miles in length—a still more valuable and thoroughly protected anchorage for vessels of the largest size, and occupied by men-of-war. In the Channel, 14 miles off the Sound, is the dangerous Eddystone Reef (q.v.), indicated since 1700 by lighthouses, and now rather a directing post to the port than a danger. Plymouth Sound is exceedingly beautiful, and has even been considered worthy of rivalship with the Bay of Naples. On its western shore is Mount Edgcumbe, the delightful seat of the Earl of Mount Edgcumbe, traditionally said to have been selected by Medina Sidonia as his share of the English spoil. Rame Head, crowned by the ruins of a mediæval chapel, is one of the most picturesque headlands on the coast; and the estuary of the Yealm, with the peaked Mewstone at its mouth, is full of romantic beauty.

See R. N. Worth's *History of Plymouth* (1871; new ed. 1891), and *The Three Towns Bibliotheca* (1873); L. Jewitt's *History of Plymouth* (1873); and four works by J. B. Rowe (1873–76).

Plymouth, (1) capital of Plymouth county, Massachusetts, on Plymouth Bay, 37 miles by rail SE. of Boston, is famous as the landing-place of the Pilgrim Fathers (q.v.). Plymouth Rock is a granite boulder at the water's edge on which they landed. It is covered by a handsome granite canopy, and there is also a national monument (1858–89) to the pilgrims; the pedestal, also of granite, stands on a hill overlooking the landing-place, and is 46 feet high, surmounted by a central figure of Faith, 36 feet high, with four immense stone figures representing Morality, Education, Freedom, and Law around the base. In Pilgrim Hall (1824–25) are preserved many relics of the first settlement of the country. The town has an iron-foundry and zinc-rolling mills, and manufactures cotton and duck, cordage, nails, tacks, and rivets. It is popular as a summer-resort, and contains a number of hotels. Pop. (1885) 7239.—(2) A mining town of Pennsylvania, on the Susquehanna River, 20 miles by rail SW. of Scranton. Pop. (1890, mostly foreigners) 9344.—(3) The capital of Montserrat (q.v.).

Plymouth Brethren, a name given by others to a body of Christians which since 1830 has extended itself throughout the British dominions and in some parts of the continent of Europe, particularly among the Protestants of France, Switzerland, and Italy, and also in the United States of America. It originated in a reaction against exclusive High Church principles, as maintained in the Church of England, with everything of a kindred nature in other churches, and against a dead formalism associated with 'unevangelical' doctrine. Some of the first members of the new religious communities formed in Plymouth and elsewhere were retired Anglo-Indian officers, men of unquestionable zeal and piety; but these communities began to appear almost simultaneously in a number of places. Their origin is, however, very much to be ascribed to the labours and influence of John Nelson Darby (1800–82), from whom the Plymouth Brethren on the continent of Europe are very generally known as *Darbyites*. Darby was a barrister, who under deeply religious impressions became a clergyman of the Church of England, and served as a curate in Wicklow; but in 1827 he left the Church of England from conscientious scruples, and became an evangelist unconnected with any church. In this character he laboured both in England and on the continent of Europe, preaching in French, English, and German. It was in 1830 that he founded at Plymouth the congregation whence comes the name usually given to the communion; the Dublin assembly dates from the same year. He also gave utterance to his opinions in numerous pamphlets, in a quarterly periodical, and a long series of theological works. His tenets, and those of the Brethren in general, are strictly Calvinistic: original sin and predestination, the efficacy of Christ's sacrifice, the merit of His obedience, the power of His intercession, the gracious operations of the Holy Spirit in regeneration and sanctification are prominent points. Pre-Millenarian views are generally entertained by the Brethren; and they usually practise the baptism of believers without regard to previous infant baptism. Recently among a section household baptism has been practised. They partake of the Lord's Supper every Sunday, or 'first day of the week.' They utterly reject the rite of confirmation. Their most distinctive peculiarity, when contrasted with other Calvinistic churches, is their complete rejection of ecclesiastical organisation. They suppose the whole Christian body in the world to have declined from truth and duty, like Israel of old, and therefore to have been 'corporately rejected of God,' and believe that the church consists of all true believers in the Lord Jesus to whatever denomination they may belong—holding uniformly that no unbeliever or unregenerate person ought to be recognised as in the church of God. They refuse to recognise any humanly devised form of church government, or any official or salaried ministry; they insist on the privilege and responsibility of every individual to minister according to his gift and ability, in order to the edification of the whole. Practically the number of those fitted publicly to teach or minister the Word of God is very limited, and those who are not fitted for such ministry are not encouraged and sometimes restrained.

They distinguish widely between pastors, teachers, and exhorters, whose ministry is to the church, and evangelists, whose ministry of the gospel is toward the world. Whilst disowning human qualifications and ordination as generally practised, and condemning wholly as unscriptural the distinction of 'clergy and laity,' they hold that it is right to own such evangelists, pastors, and teachers as Christ the Head of the Church has bestowed and the Holy Spirit has qualified. Such as devote themselves wholly to the work of the gospel are supported by voluntary and unsolicited contributions. In their assemblies there are frequent pauses, and liberty

therefore for any member to lead in prayer or praise or to exhort or teach as he may judge to be for edification, guided by spiritually enlightened understanding of what is fitting and in harmony with what has gone before. Women are not allowed to take public part in the assembly. Persons proved to have been guilty of the sins mentioned in 1 Cor. v. 11 are excluded from the fellowship, as well as those who deny foundation truths of Christian doctrine, until evidence of repentance satisfactory to all is forthcoming. The Plymouth Brethren reject every distinctive appellation but that of Christians, although a special denomination is found necessary to designate them; no one not holding their views could remain associated with them. A schism took place among them in consequence of doctrines preached at Plymouth concerning the human nature of Christ; Darby vigorously opposing what he deemed a dangerous error, and he and his adherents utterly separating from the fellowship of those who maintained it, or refused to condemn it, and also from all who, even though personally clear of the error, refused to endorse the extreme form of separation demanded by Darby. The Darbyite section since Darby's death has been more than once divided about various questions of doctrine and discipline. The less exclusive principles have attracted many earnest Christians out of all denominations, and the meetings continue to multiply and increase in Great Britain and Ireland, Canada, the United States, Australia, New Zealand, and elsewhere. The increase is mainly the result of evangelistic work. In the United Kingdom there are about 800 meetings; in Canada, over 100; in the United States, about 100; in Germany, 200; in France, 150; in Switzerland, 80; and in Holland, some 40.

See the works of Darby, Kelly, C. H. Mackintosh, and J. G. Bellett; and books for or against the doctrines of the Brethren by Trotter (1856), Groves (1867), Reid (1875), Miller (1879), Teulon (1883).

Pneumatic Despatch, the name given to a method of sending written documents, chiefly telegraphic despatches, through a comparatively narrow tube by means of compressed air and by a partial vacuum. Early in the 19th century Mr Medhurst proposed to construct a railway on this principle with carriages moving through an air-tight tunnel (see MURDOCK). But Mr Latimer Clark, C.E., was the first to carry out a plan for the transmission of telegrams by pneumatic power. In 1853 he got a tube laid between the central station of the International Telegraph Company and the Stock Exchange, London, through which a carrier containing despatches was propelled by a current of air produced by connecting the tube with a vacuum holder. An improvement on this was made in 1858 by Mr Varley, C.E., who introduced compressed air for the outward and retained the vacuum method for the inward traffic. This method is still in use.

The essentials of a pneumatic despatch are the exhausting and compressing pumps worked by a steam-engine or other motor; a metal tube, which in England is usually a lead pipe, since it is easily made air-tight by soldering the joints; a small carrier of gutta-percha or other material to contain the despatches; and a suitable arrangement of valves at the stations for connecting the tube or tubes with the compressed air or vacuum mains. It has been found by experience that with heavy traffic, such as that at the telegraphic department of the London Post-office, a lead pipe 2¼ inches in diameter is a convenient size, and this is enclosed in an iron pipe for protection. The method of working is this: At the central station end of the tube there is a double sluice valve, and when the carrier is inserted into the message chamber (the widened end of the pipe) the lower slide of the valve is drawn so as to close the mouth of the pipe, but on the rod of the slide there is a stop which actuates a lever and rack, and this opens the upper slide in front of the carrier. At the same time, by a separate arrangement, a valve is opened to admit compressed air, which forces the carrier forward. When its arrival at the other end of the tube is signalled electrically, the slide is moved so as to cut off the air from the pressure main, and then the chamber at the mouth of the pipe is ready for another carrier. From the distant end of the pipe the carrier is drawn or sucked to the central station by making a connection at that station with the vacuum main instead of the pressure main. For a distance of 1000 yards with a 2¼-inch tube the time of transit is one minute when the air pressure is 10 lb. per square inch or with an equivalent effective vacuum of 6½ lb. per square inch. With the air pressure and vacuum usually employed, a speed of from 25 to 35 miles per hour is attained in tubes not exceeding a mile in length. The speed varies inversely as the square root of the length of the tube. The pneumatic service of the British post-office has been gradually increasing until the system, which in 1854 was represented in London by one 6 horse-power engine working a single tube of a few hundred yards in length, comprised in 1900, in London alone, four 50 horse-power engines (each indicating 130 horse-power) and 81 tubes of an aggregate length of 34 miles, in constant operation between 42 stations. The newspaper offices in several of our large towns have pneumatic despatches in connection with the telegraphic instrument rooms of their respective post-offices. In Paris (which has 20 stations for post-office work) and some other towns on the Continent, instead of several tubes radiating from a central to outlying stations as in London, one tube or tubes alongside each other from the central telegraph office form a continuous circular line with intermediate stations, and several carriers linked together are sent at one time. In some of these continental pneumatic despatches the pipes are of iron instead of lead, and there are other differences of detail. Berlin has 28 miles of tubing between 38 stations. In the United States great progress has been made in the use of pneumatic power for post-office work. Mr B. C. Batcheller, an American engineer, has invented an improved system which, from its completeness and simplicity, gives promise of very extended use in future. It consists of double tubes of wrought iron running parallel to each other. At the central station a steam-engine of 25 horse-power for every mile of tube compresses the air and forces it into one of the tubes, along which it rushes, returning by the other, a constant current being kept up. Cylinders of steel weighing about 13 lb., and having a capacity of about 800 cubic inches, are loaded with the letters, or whatever is to be sent, and, by an ingenious arrangement, introduced into the tube without interrupting the current. They are propelled at the rate of the current, and on arrival at the terminus are delivered into an air-chamber which stops them, also without interrupting the current, which returns by the other tube. At intermediate stations another ingenious device delivers cylinders, specially fitted for each station, at the proper places. The system was first tried in Philadelphia in 1893, the tubes used being 6 inches in diameter. One of the lines, 1 mile in length, was traversed in 85 seconds. In Boston 8-inch tubes were used, and carried over 360,000 letters per day between the post-office and the railway station. New York post-office has three sets of tubes: one to the Grand Central Station (3½ miles), with 3 intermediate stations, carries 6000 lb. of letters daily at the rate of 7 minutes each way. In 1900, by

sanction of the authorities, Mr Batcheller formulated a complete scheme for London. Its use for small parcels as well as letters and telegrams might do much to relieve the congested traffic in the streets.

It has been several times proposed to utilise the pneumatic tube for passenger traffic, and a piece of railway of this kind was laid down in the Crystal Palace grounds in 1865 by Mr Rammel. It consisted of a single line of rails in a tunnel 600 yards in length, along which a carriage carried passengers. Motion was given by alternate blowing and suction; but it was little more than an experiment, and was not permanent. Electricity has proved a much more useful power than air for this purpose.

Pneumatic power is capable of application in many other directions. It is extensively used in working tools of all kinds for riveting, hoisting, drilling, metal-cutting, hammering, &c.; and it is in many cases superseding steam and rivalling electricity (see COMPRESSED-AIR MOTOR). The London and North-western Railway Company were in 1901 preparing to introduce into their system a method of working their signals by pneumatic power, which has been successfully used in many American lines. The motive-power will be compressed air contained in an underground pipe, the pressure of which will, by means of pistons, be made to work signals at any reasonable distance. The action will be quicker; fewer signalmen will be required; the complicated system of rods and levers will be dispensed with; the new apparatus will not be so apt to get out of order as the old, and will be much cheaper to maintain. See also AIR-ENGINE.

Pneumatic Gun. See AIR-GUN, CANNON.

Pneumatics is a name, not very much used now, for the science that discusses the properties of gaseous fluids. It is therefore a branch of Hydrodynamics (q.v.), in the modern acceptance of that term. See also ATMOSPHERE, BAROMETER, GAS, SOUND, VISCOSITY, WAVE, WIND.

Pneumatic Trough is a piece of chemical apparatus devised by Priestley, by means of which gases can be collected in vessels for experiments or examination. It consists of a vessel of water, provided with a ledge or shelf at the depth of two or three inches from the top. The jars in which the gas is to be collected are filled with water, and placed with their mouths downward upon the shelf, which is kept a little under water, so as to prevent the entrance of air into the jars. When the edge of the jar is brought over the extremity of the tube carrying the gas the bubbles of gas rise through the water, collect in the upper part of the jar, and displace the liquid.

Pneumogastric Nerve. See NERVOUS SYSTEM, Vol. VII. p. 441, and DIGESTION; also Habershon, *Pathology of the Pneumogastric Nerve* (2d ed. 1885).

Pneumonia, or Inflammation of the Lungs, is the name applied (with the necessary qualification) to a number of distinct pathological conditions. The catarrhal inflammation of Bronchitis (q.v.) may extend to the alveoli of the lungs, producing scattered patches of *catarrhal pneumonia*. The inflammatory changes in the lungs in consumption, including *interstitial pneumonia*, or *cirrhosis* of the lungs; in a few cases of syphilis; in wounds and injuries of the chest; in pyæmia; in the last stage of many exhausting diseases, all come under this head. But the most important form, to which the present discussion will be restricted, is that variously called *acute*, *idiopathic*, *lobar*, or *croupous pneumonia*, and is one of the most striking and definite of familiar diseases.

The changes occurring in an affected portion of lung are described in three stages. (1) *Congestion:* the lung-tissue still contains air, though less than in health, and is gorged with blood. (2) *Red hepatisation:* the lung-tissue is solid like liver (hence the name), and is much more friable than in health; it still contains much blood, but no air, as the vesicles are completely filled with firm exudation, consisting of fibrinous material, mixed with leucocytes and red blood-corpuscles. (3) *Gray hepatisation:* the tissue is still more friable and of a grayish colour, containing now little blood or blood pigment; the exudation has become much softer, as the fibrinous material has disappeared, and it oozes in part from the cut surface as a purulent fluid. It is doubtful whether recovery can take place when this third stage has been reached. When the surface of the lung is affected Pleurisy (q.v.) is always present as well as pneumonia.

The inflammation never attacks the whole of both lungs at once; the right is more often affected than the left, and the lower part than the upper. A whole lobe, or a large part of it, usually suffers; sometimes more than one.

The disease generally begins suddenly with a severe rigor or shivering-fit, and the temperature rises rapidly—usually to 103°–105° F. The pulse and respirations are both quickened, but the latter much more in proportion than in most other diseases, a most important indication of the nature of the case: instead of the usual ratio (about 4 pulse-beats to 1 respiration), the proportion becomes 3 or 2 to 1. All the usual signs of fever are present; but the patient's face presents a characteristic dusky flush; there is frequently severe pain in the affected part of the chest, and usually more or less cough, painful, but short, and suppressed as far as possible. In most cases after a few days the spit becomes very viscid and tenacious, and assumes a rusty tinge; this appearance is almost sufficient by itself to show the nature of the disease; but spit as well as cough may be absent altogether. The physical signs of the disease are very distinct. There is dullness on percussion over the affected area; and on auscultation marked and very characteristic changes in the breath-sounds. But if the inflammatory process happen not to reach a portion of the lung in contact with the chest-wall it may be impossible to detect anything abnormal.

It is always a serious disease; but the great majority of cases do recover. The circumstances which make it most alarming are the presence of other disease, especially of the heart or kidneys; previous habits of intemperance; and advanced age, as it is much less fatal in youth and middle life than after the age of sixty. Yet sometimes even cases apparently far from hopeful ultimately do well.

In favourable cases the fever usually terminates very rapidly, *by crisis*, as it is termed; in a few hours the temperature falls five or seven degrees, and the patient's discomfort becomes correspondingly relieved. In a very large proportion of cases this takes place between the sixth and the eighth day; but it may occur earlier, or it may be delayed to the fourteenth. After this has taken place the exudation in the affected portion of lung is gradually expectorated and absorbed, and as a rule perfect recovery takes place.

In a considerable number of cases pneumonia seems to be brought on by exposure to cold or wet. But in the majority no such cause can be traced. Only in very exceptional instances does it seem to be infectious; but epidemics on a small scale are of not infrequent occurrence, and sometimes assume large proportions. These facts, among others, have led many observers to believe that acute pneumonia ought really to be classed not with local inflammations, but with specific fevers; and that the

inflammation in the lung has the same relation to the disease as the ulcers in the intestines to typhoid fever, or the inflamed throat to scarlet fever. In 1882 Friedländer described a form of micrococcus as occurring in the lungs in pneumonia. But it is doubtful whether it is always present in this disease, and it is sometimes found in other conditions. It must at present be regarded as an open question whether it is really a simple inflammation, with accompanying febrile disturbance, or a disease analogous to the infectious fevers, with a special local manifestation in the lungs.

The recognised treatment of pneumonia passed through curiously varied phases during the 19th century. Free and repeated bleedings, with extensive use of mercury, in vogue during the earlier decades, were superseded about the middle of the century by equally extensive administration of alcoholic stimulants. But it was gradually discovered that many cases recover perfectly with no other treatment than careful nursing; and the usual practice in recent times has been to assign to drugs only a subordinate place. Rest in bed in the recumbent position; a plentiful supply of fluid nourishment; light poultices, or a thick layer of cotton-wool, over the affected part, are often all that is necessary in a young and healthy subject. Severe pain may be combated by mustard poultices, blistering, or leeching; or it may require anodynes for its relief; sleeplessness, excessive rise of temperature, troublesome cough, or aggravation of any other symptom may require special treatment. The danger most to be feared in this disease, however, is generally weakness of the heart; and to patients of feeble constitution or advanced age stimulants —digitalis, ammonia, alcohol, &c.—are usually administered, often in large and frequent doses. See Sturges and Coupland, *History and Relations of Pneumonia* (2d ed. 1890).

Po (anc. *Eridanus* and *Padus*), the largest river of Italy, rises on Monte Viso, one of the Cottian Alps, at an altitude of 6405 feet, close to the French frontier. It flows eastward for upwards of 20 miles, when, arriving before Saluzzo, it emerges from its rocky defiles and enters upon the plain. From Saluzzo it flows north-north-east past Turin to Chivasso; there it changes its course toward the east, in which direction it flows to its embouchure in the Adriatic. Upwards of 55 miles from its mouth, above Ferrara, it begins to form its delta, 60 miles wide from north to south. The delta is growing rapidly in area. Ravenna, a city once on the seashore, now stands 4 miles inland. The Po receives from the left the Ticino, Adda, Mincio, and other streams, and from the right the Trebbia and others. It has an entire length of 360 miles, and drains an area of nearly 28,900 sq. m. Below Piacenza its stream has from pre-Roman days been embanked—in some places with double embankments; and the bed is now high above the plain. It has always been difficult to cross, owing to its width and, still more, the great volume of its waters; hence the strategic and commercial importance of such places as Piacenza and Turin, where the easiest fords are.

Poaceæ. See Grasses, Pasture.

Poaching, though not strictly a legal term, has so long been appropriated in popular speech to describe a well-known offence that it is now usually adopted in legal works. It means trespassing on another's lands in pursuit of game; and it is likewise extended to the cognate offence of unlawfully fishing in another's waters.

(1) *As to Poaching Game.*—The general law as to who is entitled to game, and in what circumstances, is stated under the head Game-laws. In England there are a Day Poaching Act and a Night Poaching Act, imposing penalties on poachers. By the Day Poaching Act, 1831, whoever unlawfully goes upon lands not his own to pursue or kill Game (q.v.), rabbits, woodcocks, snipes, quails, or landrails is liable to a penalty of £2. Any person whatever, whether interested in the lands or not, may institute the proceedings for the punishment of the poacher; and the informer is entitled to half the penalty, the other half going to the poor of the parish. When a poacher is found trespassing on lands in search of game the person entitled to the game there, or the tenant, or a gamekeeper or servant of either may demand the poacher's name and place of abode, and if it is refused may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is entitled to go at large. In such a case a penalty of £5 may be inflicted. If game be found on the poacher at the time he is caught, and it appear to have been newly caught, the party who is entitled to arrest him is entitled to seize the game also. If the poacher when convicted do not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding two calendar months. The party may appeal against his conviction to the Court of Quarter Sessions; but he must either remain in custody in the interval, or give security for the costs. The offence of poaching is punished more severely when five or more go out together, and in such case each is liable to a penalty of £5. Moreover, if any of these five or more persons, acting in concert, be armed with a gun, and use violence, each is liable to an additional penalty of £5. By the Night Poaching Act, 1828, which applies to the United Kingdom, it is provided that any person by night—i.e. between the first hour after sunset and the first hour before sunrise—unlawfully trespassing in search of game shall for a first offence be committed by the justices to the house of correction for a period not exceeding three months; for a second offence shall be committed for a period not exceeding six months, the convicted person being in each case liable to a further term of imprisonment on failure to give securities at the end of his sentence; and for a third offence shall be guilty of a misdemeanour, and be liable to penal servitude or two years' imprisonment. In case such night-poachers are found on the lands and in the act, the owner or occupier of the land or his servants may arrest the poachers, and take them before justices. If the night-poacher, when arrested, use firearms, sticks, or offensive weapons, he shall be guilty of a misdemeanour, and be punishable by penal servitude or two years' imprisonment. In case of three or more night-poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanour, and is liable to penal servitude or imprisonment for three years. The provisions of the Night Poaching Act were, by the amending Act of 1844, extended to public roads and highways, it having been found that the original act was evaded, and the risk of murder greatly increased by poachers frequenting such places.

Under the former law it was, as already mentioned, incompetent for any person except the owner or occupier of the lands or their servants to apprehend the poacher, and even this could be done only when the poacher was caught in the act on the lands; and hence even constables had no power to seize the poacher, though seen to be coming from such lands. But by the Poaching Prevention Act, 1862, which applies to the United Kingdom, if a constable meets a suspected poacher in any public place, whom he has reason to suspect of

coming from land where he has been poaching, and of having in his possession game unlawfully got, or a gun or net, such constable may stop and search the poacher; and if game, or implements for taking game, be found on him, may seize and detain them, and summon the poacher before the justices. When before the justices, if it be proved by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used for poaching, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may have so used. The constable may also stop and search any cart in which he suspects there may be such game or implements. The person convicted may appeal, if he chooses, to the next Quarter Sessions, or, in certain cases, to the Court of Queen's Bench. A conviction can be obtained only in cases of actual seizure of game or implements, but for a conviction it is not necessary that the poacher should be seen actually committing the offence. Poaching hares or rabbits by night in any warren or breeding-ground is a misdemeanour under the Larceny Consolidation Act, 1861. This act does not apply to Scotland.

As game is in the category of wild animals, in England the poacher is entitled to keep the game unless it was both started and caught on the same person's lands. But, as stated above, game may be taken from a poacher if the demand is made at the time on the land or on fresh pursuit.

The law of Scotland as to poachers does not materially differ from that of England, and the Night-poaching Acts apply to Scotland. The Scots Day Trespass Act, 1832, closely agrees with the English Act. In Scotland game is the property of the captor, and accordingly where there is no statutory forfeiture the offender is entitled to retain game found in his possession. It is not necessary under the Scots Day Trespass Act for the seizure of game in the possession of a poacher that the game should have been recently killed. A third offence of night-poaching in Scotland *must* be tried before the High Court of Justiciary, and the offender, if convicted, is liable to penal servitude. In Ireland the law as to poaching is not identical with the law of England, but substantially the provisions are the same.

The law of the United Kingdom has often been described as too severe against poachers, inasmuch as most of the penalties, except in Ireland, are cumulative. But it is answered that poaching is in reality only stealing under a milder name, game being as much the fruit of the soil, dependent upon the care and protection of the owner or occupier, as apples or turnips, and that the transition from habitual poaching to stealing is not only easy, but inevitable. The administration of the law by justices, many of whom preserve game, is also objected to. As regards Scotland this objection has been removed by the Game Laws Amendment Act, 1877, under which all summary prosecutions for poaching must be conducted before the sheriff or his substitute.

See Oke, *Game Laws* (new ed. 1881); Neville, *Game Laws* (new ed. 1884); Forbes Irvine, *Game Laws of Scotland;* A. Porter, *The Gamekeeper's Manual* (2d ed. 1889); Kent, *The Fish and Game Laws of the State of New York* (1888); and, for other sides of the subject, R. Jefferies, *The Gamekeeper at Home* (1878), and *The Amateur Poacher* (1880); John Watson, *Poachers and Poaching* (1891).

(2) *Poaching Fish* is the unlawfully entering on another's fishery in order to catch fish. *Salmon-poaching* will be found treated under the head of SALMON. The law of fisheries is not uniform in the United Kingdom. In England the general rule is that any one of the public may fish freely in the sea and in all navigable rivers as far as the tide flows; and where he can fish he can catch salmon as well as every other kind of fish. But there is an exception to this generality, which consists in this, that as the crown could before Magna Charta (which took away such right) legally grant a several or exclusive fishery in the sea or a tidal river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove that he has exercised this exclusive right as far back as one or two centuries it will be inferred that his right dates from before Magna Charta, and it will therefore be sustained. When such is the case the public have no right to fish even in a tidal river or the sea at the specified places, the sole fishery being vested in this individual owner. In streams not tidal the rule is that each riparian owner—i.e. the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle line of the stream. If he is owner on both sides of the stream then he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of the soil is the owner of a several fishery therein. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands abutting thereon; but much will depend on the title to the lands and the subsequent user. As a general rule, there is no such thing as a right in the public to fish anywhere except in a tidal river or the sea, and that is subject to the exception of an individual claiming a several fishery, as before mentioned. It is often supposed that if a highway adjoins a private stream any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the purpose of fishing or pursuing game, the use of the highway, so far as the public are concerned, being confined to the purposes of travelling or transport. The general rule as to all several—i.e. exclusive—fisheries is that whoever poaches the fish commits an offence, for which he may be summoned before justices and fined £5, over and above the value of the fish taken; and if the fishery where he poaches is adjoining the dwelling-house of the owner of the fishery it is a still higher offence, for it is then an indictable misdemeanour. The Fish-poaching Code of England is contained in the Larceny Act, 1861. It is immaterial what kind of fish is caught by poachers, and how they are caught. But a milder punishment is awarded to the poaching *angler*, for even though he poach in a fishery adjoining the owner's dwelling-house he incurs only a penalty of £5; and where the fishery does not adjoin a dwelling-house he incurs a penalty of only £2. Whenever a fish-poacher, other than an angler, is caught in the act of poaching he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this can only be done while he is on the spot or near it, for if he escape to the highway or to other lands before being arrested he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect a privilege is given to *anglers*, for in no case can these be arrested, if angling during the daytime; they can only be summoned for the offence. The poacher, when arrested, must be taken within a reasonable time before a justice of the peace, and charged with the offence. In regard to the fish poached the rule is that whoever first catches the fish, whether legally or illegally, is entitled to keep it; so that the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is

provided by an express section of the Larceny Act, 1861, that the owner of the fishery or land where the poacher is caught, or his servant, may demand, and if refused may seize, the net, rod, line, hook, or other implement used for taking the fish, but no other person can seize these. Large powers to arrest are given to water-bailiffs acting under the Fresh-water Fisheries Act, 1878.

The law of Scotland differs considerably from that of England. As regards fish other than salmon the general rule is that the riparian owner is entitled to catch all the fish he can, provided he do not interfere with the superior right of some crown grantee of the salmon-fishery. A person who poaches trout or other fresh-water fish with a net, or by double-rod fishing, or cross-line fishing, or set lines, &c., incurs a penalty of £5, besides forfeiture of the fish caught. And he may be arrested if he is net-fishing, but not if he is fishing in another way. Moreover a mere angler of trout, though a poacher, cannot be arrested nor yet punished by any penalty; though he is liable to an action of interdict. In the case of all poachers of trout (except angling poachers, who can neither be arrested nor yet have their fish or fishing-rod taken from them by force), the owner of the fishery or any person authorised by him may seize the nets, boats, and fishing implements if the poachers are found on the spot. See the Fresh-water Fisheries (Scotland) Acts of 1845 and 1860. The public have no right to angle from a highway adjoining a stream. Where a stream runs through a farm the farmer has no right to angle for trout, unless the lease expressly allows it. The Irish law is practically the same as the English.

See Paterson's *Fishery Laws* (new ed. 1873); Oke's *Fishery Laws* (new ed. 1884); and, for Scotland, Stewart on *Rights of Fishing* (1869).

Pocahontas, daughter of an Indian chief, Powhatan, born about 1595, figures prominently in the American travels of Captain John Smith (q.v.) in connection with the part she played in the history of the early English colonists in Virginia. The expedition under Captain Bartholomew Gosnold and others had landed in Chesapeake Bay in 1607. The James River was explored, and a settlement formed, but a great drawback was the lack of food-supplies. In one of the expeditions for food, and to explore the Chickahominy, Smith was taken prisoner, brought before the chief Powhatan, and his head laid on a stone preparatory to having his brains beaten out with clubs. At this juncture Pocahontas, then a young girl, 'when no entreaty could prevail, got his head in her arms, and laid her own upon his to save him from death.' She again saved Smith's life in 1609 by informing him of a plot by her father against him. She was brought a prisoner to Jamestown by Captain Argall in 1613. She married an Englishman, John Rolfe, in 1614, is said to have embraced Christianity, and came to England with her husband in 1616. During her residence of seven months in England Smith petitioned Queen Anne on her behalf. Having embarked with her husband for Virginia, she died off Gravesend in March 1617. She left one son, and a branch of the Randolphs and several other Virginia families claim descent from her (Robertson and Brock, *Pocahontas and her Descendants*, Richm. 1887). Charles Deane, in his notes to his reprint of Smith's *True Relation* (1866), first started doubts as to Smith's veracity in connection with the Pocahontas incident, and this scepticism has been shared by other writers. But Professor Edward Arber in his reprint of Smith's works (1884) holds implicitly to the truth of the story, which, after a most rigorous test, he declares is a solid historical fact.

Pochard (*Fuligula*), a genus of diving ducks which are marine during the greater part of the year. One of their distinctive structural features is a membranous lobe on the hind toe. The Common Pochard (*F. ferina*) is a winter visitor to Britain, and sometimes breeds by the shores of inland meres. The Red-crested Pochard (*F. rufina*) is a rare wanderer to Britain; so is the Ferruginous (*F. nyroca*), while the Tufted (*F. cristata*) and the Scaup (*F. marila*) are much commoner, and sometimes breed in suitable inland resorts. Nearly allied to *F. ferina* is an American species (*F. americana*), and the Canvas-back Duck (q.v.) also belongs to this genus.

Pocklington, a market-town in the East Riding of Yorkshire, 16 miles ESE. of York. It has a good Early English church (restored 1850) and a grammar-school (1514; reconstituted 1876), where Wilberforce was educated. Pop. 2733.

Pocock, Edward, a learned Orientalist, was born in 1604, and educated at Corpus Christi College, Oxford, of which he was elected fellow in 1628. He early devoted himself to oriental studies, and sailed for Aleppo in 1630 as chaplain to the English factory, but returned in 1636 to fill Laud's newly-founded Arabic chair at Oxford, and received in 1643 the college living of Childrey. His estimable character and great learning raised up for him during the troubles friends like Selden and Owen. He was appointed to the chair of Hebrew in 1648, but his inability to take the engagement of 1649 deprived him of the salary down to the Restoration. He survived till 1691. Pocock's learning was really remarkable, even apart from all allowances for his time. His *Specimen Historiæ Arabum* (1649), abridged from Abulfaraj; *Porta Mosis* (1655)—extracts from Maimonides' Arabic commentary on the Mishna; the Annals of Eutychius (1656), in Arabic and Latin; and an edition of the Arabic history of Barhebræus (1663), were followed by Commentaries on Micah (1677), Malachi (1677), Hosea (1685), and Joel (1691).

Pococke, Richard, 'the Traveller,' was born at Southampton in 1704, and educated there and at Corpus Christi College, Oxford. Precentor successively of Lismore and Waterford, then Archdeacon of Dublin (1745), in 1756 he was consecrated Bishop of Ossory, and had just been translated to Meath, when, on 15th September 1765, while on a visitation, he died very suddenly at Charleville, near Tullamore. His travels, which took up nearly nine years of his life, and in which he must have ridden some 52,000 miles, are described in two folios dealing with his four years' wanderings in Syria, Egypt, and Mesopotamia (1743–45), in a volume on his tours in Scotland (Scottish History Soc., 1887), in two on his tours through England (Camden Soc., 1888–89) and in one on Ireland (edited by J. T. Stokes, 1891)—books that are as dull as they are valuable. Pococke was, moreover, the pioneer of Alpine travel, for in 1741 he led a dozen Englishmen, all strongly armed, to the Vale of Chamouni, whose grateful inhabitants carved his name and the date on a huge granite boulder close to the Mer de Glace.

Pod. See Fruit.

Podagra. See Gout.

Podargus, a genus of birds nearly allied to the true Goatsuckers. They are at home in New Guinea and Australia, are arboreal and nocturnal in their habits, and feed on large insects, which are mostly caught about the trees. Some of them are so sleepy during the day that Gould says they may be occasionally caught by the hand, or one may be shot without waking its neighbour. They make rough nests in the eucalyptus or casuarina trees, lay two eggs of spotless white, and the

work of hatching is shared by both sexes. A podargus is usually larger than a goatsucker, and has a wider gape; the oil-gland seems to be absent, and the rump bears two remarkable tufts of small brittle feathers, known as 'powder-down patches.' One of the Australian species, *P. cuvieri*, disturbs the night by a hoarse cry resembling the syllables *More Pork* or *Mopoke*, by which names it is therefore known in New South Wales.

Podestà (Lat. *potestas*, 'power'), an Italian municipal magistrate, sometimes with supreme administrative and military power, sometimes merely judicial.

Podgoritza, a fortified town of Montenegro, 16 miles E. of Cetinje, ceded by Turkey in 1879. Pop. (1895) 6534.

Podiebrad. George Boczko of Podiebrad, Bohemian king, was born of a noble family at Podiebrad on 6th April 1420, and became an adherent of the moderate party of the Hussites (q.v.). When the Catholic barons (1438) carried the election of Albert V. of Austria (II. of Germany), Podiebrad allied himself with the Utraquists in Tabor, who offered the sovereignty of Bohemia to Casimir, king of Poland. After forcing Albert to raise the siege of Tabor and retire to Prague, Podiebrad was recognised as the leader of the Utraquists; then he seized upon Prague (1448), and got himself made governor or regent of Bohemia, from 1453 to 1457, for the young king Ladislaus. On the death of Ladislaus, Podiebrad was chosen his successor, and was crowned early in 1458. By skilful management and wise policy he succeeded in allaying the bitternesses of religious zeal, but only for a while. In 1462 he decided to uphold the terms of the *compactata* of Prague (1433); this angered the pope, Pius II., and he was only prevented from excommunicating Podiebrad through the special intervention of the emperor. The next pope, however, Paul II., did in 1466 promulgate against him the ban of excommunication. Matthias Corvinus of Hungary was the only prince who took the field to enforce it; but him Podiebrad surrounded at Wilamow (1469) and forced into a truce. Nevertheless Matthias was crowned king by the Catholic barons at Olmütz immediately afterwards. Podiebrad died on 22d March 1471, having already made arrangements whereby a Polish prince should succeed him.

Podocarpus. See Coniferæ.

Podolia, or Kamenetz, a government of West or 'White' Russia, north of Bessarabia, and bordering on the Austrian frontier. Area, 16,224 sq. m.; pop. (1891) 2,617,253, the majority of whom are Russniaks. The surface is a tableland, strewn with hills; nearly three-fourths is either arable or available for pasturage.

Podophthalma (Gr., 'stalk eyed'), a name often applied to a section of Crustacea (q.v.).

Podophyllum, a genus of plants comprising two species, variously ranked by botanists in the natural order Ranunculaceæ, or made the type of a small distinct order, Podophylleæ or Podophyllaceæ, differing from Ranunculaceæ chiefly in having a solitary carpel. The genus Podophyllum has three sepals, six to nine petals, twelve to eighteen stamens, a broad round stigma, seated almost on the top of the germen, and a many-seeded berry. *P. peltatum* is a perennial plant, common in North America, growing in moist woods and on the shady banks of streams, and is known as *May-apple*, because it flowers and ripens its fruit very early in summer; also as *Hog-apple* and *Wild Lemon*. The fruit may be eaten, but is not agreeable. All the other parts are actively cathartic. The other species (*P. emodi*) is a native of the Himalayas, and has the same medicinal properties, but in 1889 was shown to yield three

Leaf, Flower, and Fruit of *Podophyllum peltatum*.

times as much of the valuable resin as the American plant.

Podophyllin is the resin obtained by means of rectified spirit from the root. In the British Pharmacopœia the root is officinal, but is only used to prepare the resin (*Podophylli Resina*). The latter is an active purgative, and seems to have the power of relieving the liver by exciting copious bilious discharges. The dose is ¼ to 1 grain; its action is slow, generally taking about eight hours. It is apt to gripe, and hence is usually given along with carminatives, or in small doses combined with other purgatives.

Podura. See Spring-tails.

Poe, Edgar Allan, poet, critic, and romancer, was born at Boston, January 19, 1809. His mother, Elizabeth Arnold, was a young English actress; his father, David Poe, a player of loose habits, the runaway son of a revolutionary veteran at Baltimore. Orphaned at Richmond in his third year, Edgar was adopted by John Allan, a wealthy and childless merchant, who gave him more care than affection. In 1815 the family went to England, and the boy was sent to school at Stoke Newington, a suburb of London. From their return in 1820 till 1825 he attended a classical school at Richmond. The year 1826 was spent at the University of Virginia. Offended by his dissipation and gambling debts, his patron removed him to the counting-room, whence he presently absconded to Boston. Here he published *Tamerlane and other Poems*, by a Bostonian, 1827, a pamphlet of 40 pages (reprinted in London, 1884). Under the new pressure of poverty he enlisted, May 26, 1827, as Edgar A. Perry, giving his age as twenty-two. He served, apparently without fault, in the First Artillery at Forts Independence, Moultrie, and Monroe, and rose to be sergeant-major, January 1, 1829. He now effected a reconciliation with Mr Allan, who procured his discharge, April 15, and after a year's delay his admission to West Point. Meantime his second volume, *Al Aaraaf, Tamerlane, and Minor Poems*, appeared with his name at Baltimore, 1829, 71 pages. He entered the Military Academy, July 1, 1830, recording his age as nineteen. Discipline and constraint did not suit him, and by deliberate neglect of duty he caused his dismissal, March 7, 1831. By this conduct he lost any remaining hope of favour from his patron, and was thrown finally on his own resources, which were probably confined to cadet subscriptions to his *Poems*. The volume appeared as a 'second edition' (it was really a third) in

Copyright 1891 in U.S. by J. B. Lippincott Company.

New York, 1831, 124 pages, and contained *Israfel*, his earliest poem of value, and *To Helen*, in a first draft.

Of his life in Baltimore during the next two years few records remain. Here occurred his earliest love-affair, which came to nothing (see 'Poe's Mary' in *Harper's Magazine* for March 1889). Nearly the first earnings of his pen was the $100 prize won by *A MS. found in a Bottle*, in October 1833. He declined an invitation to dinner 'for reasons of the most humiliating nature—my personal appearance.' John P. Kennedy befriended him, and even, by the testimony of both, saved him from starvation. From this time he lived with his aunt, Mrs Clemm, and wrote for the *Saturday Visitor*. Not long before Mr Allan's death in March 1834 Poe made an attempt to see his foster-father, who drove him from the room; this incident, like many others in his life, has been exaggerated. His connection with the *Southern Literary Messenger* began with its publication of his tale *Berenice* in March 1835; a few months later he went to Richmond as its assistant-editor. The Clemms soon joined him, and on May 16, 1836, he married his cousin Virginia, who was then not fourteen, though a friend swore that she was 'of the full age of twenty-one.' For more than a year he worked hard and usefully on the *Messenger*, which printed many of his tales, criticisms, and poems, gaining great repute thereby. But Poe was 'irregular, eccentric, and querulous,' and these qualities, with the aid of stimulants, cost him more than one place. He left Richmond in 1837, and after a year or less in New York, of which the chief apparent fruit was *The Narrative of Arthur Gordon Pym* (1838; 198 pages), in the summer of 1838 established himself (if he could be said at any time to be established) in Philadelphia.

Here he prepared *The Conchologist's First Book* (1839), the matter of which was taken from Cuvier, Wyatt, and Brown; procured at length the publication, without profit to himself, of *Tales of the Grotesque and Arabesque* (2 vols. 1840); was connected with Burton's *Gentleman's Magazine* (1839); projected in 1840 the *Penn Magazine*, which came to nothing, and in 1843 *The Stylus*, which he never gave up the hope of starting; and for a year (1842–43) edited *Graham's Magazine*, then in the forefront of American literature. Long periods of sobriety and patient though ill-requited labour would be interspersed with fits of reckless indulgence and months of desperate poverty. His wife's dangerous illness, caused by the rupture of a blood-vessel while singing, unnerved him, and weakened his always slight power of self-direction. A second prize of $100, won in 1843 by his wonderful story *The Gold Bug*, again saved the little household from starvation or near it.

In April 1844 he removed to New York, and from October to March following assisted Willis on *The Evening Mirror*. Here *The Raven* appeared, January 29, 1845, and won immediate fame. For a few months he was associated with C. F. Briggs in the *Broadway Journal*, which became notorious by his assaults on Longfellow as a plagiarist. In this year he published a volume of *Tales*, and *The Raven and other Poems*. In the spring of 1846 he occupied the famous cottage at Fordham. Here, January 30, 1847, in deepest poverty, Virginia Poe died, an attractive and pathetic figure, retaining her fragile and childish beauty to the last; she was but twenty-four. Her mother was more than a mother to the poet, and his home life drew out what was best in his nature, and afforded such measure as he attained of happiness.

Except for *The Bells*, *The Domain of Arnheim*, the wild psycho-astronomic 'prose poem' *Eureka* (1848), and a few minor pieces, the brief remainder of his life might to advantage be forgotten. Unable to stand alone, he sought vainly, and with an eagerness that approached insanity, to replace what he had lost. He was no libertine; his writings and his life were chaste; with women he was deferential, tender, chivalrous. He idealised them on the smallest provocation, and in these latter years he could not keep his imaginings in their proper place. Mrs Whitman was not the only object of his homage, and his frantic appeals to her, strangely intermingled with bar-room potations and an attempt at suicide (November 1848), were but the most striking and pitiable indications of a mind unhinged. Two months later he was deep in pen-work, and wrote to his 'Annie' that he was '*so, so* happy,' with 'how great a burden taken off' his heart. In the spring Mrs Clemm wrote to the same 'Annie,' 'I thought he would die several times. I wish we were both in our graves.'

Starting southward, June 30, he had an attack of delirium tremens in Philadelphia. Recovering, his ticket was furnished by friends who considered it unsafe to trust him with money. He spent over two months in Richmond, lecturing there and at Norfolk, and receiving many attentions. A physician warned him that 'another such indulgence would probably prove fatal.' He became engaged to a lady of means, and about September 30 left Richmond, intending to wind up his affairs in the north and return for his wedding in October. On the 3d of October he was found in a wretched condition at a voting-place in Baltimore and removed to a hospital, where, after expressing the most poignant remorse, he died, October 7, 1849.

Poe's character has been the subject of much heated controversy. It was malignantly vilified by R. W. Griswold, whom he had chosen as his biographer and literary executor, in a *Memoir* prefixed to vol. iii. of his collected works (1850), but since suppressed. Efforts to rehabilitate his memory have been equally far from the truth. After all allowance made for the infirmities of a sensitive spirit, bearing an inherited taint and bowed down by 'unmerciful disaster,' the fact remains that he was the main author of his misfortunes. His splendid intellect seemed to lack certain qualities bestowed on common men; his moral vision was never clear, his sympathies were narrow, his will was far weaker than a man's should be. His temperament was feminine, and the 'Imp of the Perverse' was always at his heels. At forty he was no better nor worse than at seventeen, except that his constitution was undermined by excesses. Always he was isolated, absorbed, self-centred, visionary, hopelessly unpractical. He wrote to Lowell in 1844, 'My life has been *whim*, impulse, passion, a longing for solitude, a scorn of all things present.' The kindly Briggs, after months of daily intimacy, called him 'characterless' and 'utterly deficient of high motive.' It is humiliating to know that his brilliant writings found with difficulty a slow market and poor prices, but more so that he perpetually sold and resold old things for new. He was more diligent in defeating his own ends than in seeking them, in making enemies than in keeping friends. Except Willis, he quarrelled with his employers and associates; men trusted or benefited him to turn from him in the end, and usually with speed. The direst necessity could teach him prudence only by fits and starts; he was not responsible, reliable, respectable—at least, never for two years together. He worshipped Beauty, caring little for her elder sister Truth; from youth he falsified the facts and dates of his own life, so that his history became a puzzle to be solved by slow and painful labours. Profoundly unmoral, morbid and hectic in his moods, he could bear neither

prosperity nor adversity: 'any motion would upset him, and his worst falls were after successes, or with success just in sight.' A mixture of the seraph and the tramp, he oscillated between the skies and the gutter, gravitating gradually downwards, because he had no god but self. Ambition, aspiration, self-respect, and the strongest love of which he was capable—his only real love, for his devoted child-wife—could not keep him from the brandy and opium which he knew to be his poisons.

As to his genius there is little room for question. Weird, wild, fantastic, almost ghoulish (judged by its results), finding its joy in gloom and its chief inspiration in memories or imaginations of dead women, dwelling by choice and habit on themes of ruin and desolation, on the awful, the horrible, even the foul, it was yet most genuine and notable; if not of the highest order, among the most picturesque and striking gifts ever vouchsafed to man. Ideality was its strongest note, but Poe could make realism serve his turn. His ratiocinative powers, exercised about 1841 in deciphering cryptograms and detecting the plot of *Barnaby Rudge* from the opening chapters, were marvellously displayed in some of his tales, especially those of Parisian murders, which were highly praised and widely circulated in France. At home during his lifetime his amazing tales were strangely neglected, and he was known chiefly as a critic. In this capacity he perhaps deserved less praise, and certainly less blame, than has befallen him. Occasionally misled by hatred or friendship, he was usually honest, independent, and fearless—even reckless; and he was first in this field as a reformer, deriding inflated mediocrity and discerning new-born power, sometimes long before it was discovered by the public. But his proper work was poetry and imaginative prose. His parade of scholarship rested on the slightest foundation. Of humour he had no particle, and some of his tales are poor stuff: such sold more readily than his best. His verses are often strained, artificial, full of mannerisms; 'everything is subordinate to sound.' In these, and in the more personal of his tales, wherein great wit and madness mingle, he was 'the poet of a single mood.' He will be long remembered for a few poems and many masterpieces of brief, powerful, and most peculiar fiction. In his own walk he stands unsurpassed if not alone, with a halo of mystery, gloom, and terror about him.

Apart from earlier sketches, and Mrs Whitman's *Poe and his Critics* (1860), his life has been written, generally for some reprint of his works, by J. H. Ingram (1874 and 1880), R. H. Stoddard (1875; see the six-volume edition of 1884), E. L. Didier (1876), and W. F. Gill (1877). G. E. Woodberry ('American Men of Letters,' 1885) unearthed some new facts. See also E. C. Stedman's *Poe* (1881). An edition by Stedman and Woodberry contains memoir and introduction (10 vols. 1895–96); another edition (10 vols. 1895–96), published by Lippincott, has neither.

Poerio. CARLO, Italian patriot, was born on the 10th of December 1803, son of a Neapolitan lawyer who had suffered imprisonment and exile in the cause of liberty. He accompanied his father into exile, but on his return became an advocate at Naples. He was repeatedly imprisoned for his services to the liberal cause; and in 1848 he organised the famous demonstration of the 27th January, which was destined to produce the constitution of the 10th February. Under it he was successively nominated director of Police and minister of Public Instruction; but he soon resigned, and was appointed deputy for Naples to the parliament. On the 19th July 1849 he was arrested, charged with being a member of a secret society, 'the Italian Unity,' and condemned to irons. With fifteen others he was confined in one small chamber in the island-prison of Nisida. Diplomatic protests from various governments—Mr Gladstone's was declared by Garibaldi to have sounded the first trumpet-call of Italian liberty—and eloquent denunciations of the royal tyranny moved Ferdinand II. at last in 1858 to ship sixty-six prisoners to America. They persuaded the captain to land them at Cork, and Poerio returned by London to Turin. There he became a member of the parliament, and in 1861 its vice-president. He died at Florence, 28th April 1867.—The elder brother ALESSANDRO (1802–48), who fell in battle for the liberation of Venice, shared his father's exile, studied in Germany, settled in Florence, and devoted his life mainly to poetry and patriotism. His poems, which contain some of the most stirring Italian songs of freedom, have been repeatedly published. See a monograph on Alessandro by Imbriani (Naples, 1884).

Poet Laureate. See LAUREATE.

Poetry is that one of the fine arts which employs rhythmical language as the medium of its expression. The present form of the word is due to the old French noun *poëterie*, but both are derived from the Greek ποιεῖν, 'to make.' A poet was ποιητής, 'a maker or composer,' and poetry ποίησις, 'the act of making or forming.' A poem was ποίημα, 'a thing made and finished.' Into all these expressions there entered the sense of artistic fashioning, and poetry from the first was felt to be, like sculpture, painting, or music, the work of a creative craftsman. As we cannot conceive of sculpture without something carved or modelled, or of painting without something painted, so poetry cannot, in the first instance, be conceived without the coincident idea of language rhythmically arranged. If this idea be absent the term must be used allusively or figuratively, as its counterparts often and legitimately are in the cases of those other arts. But to the primitive conception of poetry rhythm is absolutely necessary. In other words, it is only by a license, and in a sense which is unscientific, that we can speak of anything which is not composed in verse as poetry. To this rule, however, there are some conventional exceptions which will presently be mentioned.

Copyright 1891 in U.S. by J. B. Lippincott Company.

Verse, therefore, is the essential vehicle of poetry, and on the varieties of versification the external form of any given poetical product depends. That species of rhythm on which verse is founded is the law of regularly recurring succession of articulate sounds. Verse was defined by Dr Edwin Guest as 'a succession of articulate sounds regulated by a rhythm so definite that we can readily foresee the results which follow from its application.' The definiteness, repetition, and formal character of verse-rhythm distinguish it from that laxer and more undulating rhythm which gives charm to fine prose. The difference is one not of amount but of kind. All good verse must be severely regulated, and must obey the laws of its own prosody. The rhythm of prose, on the contrary, must, in order to be good of its species, be unrecurrent. No greater fault can be committed in prose than the intentional or even accidental introduction of passages which can be read as verse—that is, as recurrent rhythm. Poetry, therefore, in the English sense of the term, is, in its external form, an arrangement of syllables into verses or staves, distinguished by the rhythmical accidents of quantity and accent, and effected by the law of succession.

This definition of the external form of poetry, however, is not sufficient, and to complete it is admittedly so extremely difficult as almost to defy expression. In defining the term *poetry*,

nevertheless, as an English word, the lexicographers have probably been too much rather than too little affected by the necessity of including a spiritual meaning. Hardly any one has attempted to say what poetry is without mingling the figurative with the exact sense, or at least without making the definition apply to none but good and original poetry. In speaking of sculpture and painting we do not necessarily exclude all experiments in those arts which are not successful; but poetry, in English, has come to mean something which excludes unsuccessful effort in rhythmical expression. Hence a certain confusion between the external and the internal, between a craft and an ecstasy. It would be well, perhaps, to bring the term back to its more exact meaning, but it is too late to hope to do this. Poetry must continue to mean not merely language arranged in rhythmical sequence, but verse which is also inspired by imagination, and which attains a measure of perfection in that degree at which it aims. The degree may be a low one, but if the aim is fulfilled, and the rhythmical laws are followed, the work produced must not be refused the title of poetry. The word, indeed, is capable of much expansion. Any man who has written what the world accepts as a *ποίησις*, a finished composition in verse, is allowed the name of 'poet,' and his other rhythmical experiments, even though many of them are unsuccessful, are broadly defined as 'poetry.' The presence of high imagination, and of a brilliant propriety of language, are presupposed in all that is called poetry, but the word must be extended to much that is not very lofty nor very skilful if we are not to slip into pedantry in its use. Wordsworth at one time was of opinion that the only strict antithesis to Prose was Metre; but it is simpler, as well as more exact, to understand by poetry metrical composition, not troubling ourselves more than is absolutely necessary in its definition about the quality of high imagination. This latter is essential indeed to the best poetry, but not to all poetry in the colloquial use of that term.

In some languages, and particularly in French, *rime* (constantly misspelt *rhyme*, which is a meaningless arrangement of letters formed in imitation of *rhythm*) is an essential part of the form of poetry. In other languages, as in ancient Greek and Latin, rime does not exist. In English poetry final rime, though not essential, is extremely common, and is the necessary ornament of the main classes of lyrical composition. Rime is a correspondence of sound between syllables which occur at regular intervals, and in final rime that recurrence always takes place at the end of a verse. It may be single, double, or even triple. Propriety and vigour in riming are so important a portion of the art of poetry that rime cannot be overlooked in the briefest survey. Where rime is not rejected altogether, as in blank verse (and in some strophic measures of doubtful value), it forms a main ornament of English verse-composition, and some of the most beautiful effects which poetry produces are due to the skilful arrangement of these recurrent sounds. It is only a poet of great resource and infinite accomplishment who can safely dispense with this fortunate regulation of rime. To one who knows his business it offers no real restraint, but rather a support and an encouragement. As Dryden has excellently said, 'That which most regulates the fancy and gives the judgment its busiest employment is like to bring forth the richest and clearest thoughts.'

It is a popular error that the necessity of finding a rime checks the inspiration of a poet, and that he would be more fortunate if he could contrive to do without it. The universal testimony of the poets themselves does not support this notion. The best writers of verse have been unanimous in declaring that the more distinct and spontaneous are the visions which present themselves to the brain for verse-expression the more rapidly and inevitably do the rimes occur in logical sequence, the proper word fitting into its proper place with as little conscious brain-effort as the proper tone or the proper form does in the work of the painter or the sculptor. If this be so, and it seems impossible to doubt it, the difficulty which the unskilful versifier finds in riming is but another safeguard to protect us from incompetence. For those readers who declare that rime gives them no enjoyment, and is only an interruption of the sense, we can but pray that ears may be added to them.

The recognised species of poetical composition are numerous, and are exceedingly difficult to distinguish from one another, because two or more of them may frequently be found existing side by side in the same specimen. Three principal divisions are, however, supposed to include all the minor classes of poetry under general headings. These are lyrical, epical, and dramatic poetry. In the original sense all poetry was Lyrical—that is to say, was composed to be sung to a musical accompaniment, and could not be conceived except in relation to music. But at a very early period this work of song was divided into two parts, that which was regulated by the air, and that which was expressed in recitative. In the former manner were sung all the poems which were inspired by the passions, which reflected moods individual to the poet, or which were devoted to religious aspiration. In the second manner were chanted matters of narration, statements of fact, didactic, hortatory, and philosophical disquisition. The poems on an air remained lyrical poetry proper, and continued to be more or less fitted to be sung to a musical accompaniment. The poems in recitative became what is vaguely known as Epic poetry, with its attendant classes, the Satire, the Epistle, the Tale, and the Fable. From all these the musical accompaniment soon fell away. In some eastern countries, however, narrative poetry is still, when publicly recited, accompanied by a monotonous music on a stringed instrument.

Dramatic poetry has retained, in its principal branches of Tragedy and Comedy, still less of the singing quality than epical poetry. In many cases drama has thrown off the restraints of versification altogether, and is now included in the general category of poetry partly because of its traditional form, and partly because its imaginative character still links it to lyrical and epical work. The origin of drama, however, was wholly lyrical. It was out of the dithyrambic song in honour of Dionysus that tragedy sprang. The litany was chanted by a chorus that danced as it sang, and in the process of time a single personage began to break away from the chorus at intervals, and either to express aspirations of his own, or to narrate stories of the god, or to incite the chorus to fresh exertions. Comedy had a similar beginning, and by degrees not one but two and then many actors confronted the chorus and drew it into conversation. The development of this new form of poetry was very rapid; it gained variety and a recognised code of forms within a very short time, and we now possess in the tragedies of Æschylus a body of ancient dramatic poetry still capable, as recent experiment has shown, of satisfying the demands of a modern playgoer. Here the purely lyric element, in spite of the prominence of the chorus, is already minimised in favour of the development of personal action and character, so that the subsequent transition to the form of the most modern prose tragedy

is really very unessential. All the principles of dramatic poetry may be comprised in an essay on the *Agamemnon*.

Into these three elements, then, the Song, the Statement, and the Drama, all poetry that is not of a primitive nature is capable of being resolved. That which was primitive—and of this we have to conjecture more than we can prove—was probably Song alone. But, while we divide poetry into these three elements, it is not possible to make the same easy division of poetical literature. Here are found, indeed, the three great classes, but, as has been already said, they are constantly detected existing side by side in one and the same composition. The more elaborate the species of poetry the more likely are we to find upon analysis that the classes are confounded in it. In the Song we still preserve the simplest form of poem. This is a short piece in regular recurrent rhythm, expressing with the utmost conciseness a single enthusiastic and intense personal emotion, which it pours forth without deviation at a breath. When the spontaneous outburst is over the song naturally closes.

No other species of poetry is so simple as this. The Ode, which is often regarded not merely as a lofty form of lyric, but as the typical form *par excellence*, introduces a complexity. Too long and elaborate to be sung spontaneously, it verges upon drama in calling to its aid a chorus and an antichorus of singers; upon epic by its excursions into narrative and didactic reflection. The ode, in which we include its funereal form the Elegy, remains, however, truly lyrical in its necessary dependence upon melody. Not a line of it but presupposes a musical interpretation. The traditional fixed forms suggest the accompaniment of music to a far less degree. The Sonnet, for instance, with its dignified arrangement of full lines, admitting very slight modification of form, is singularly ill-fitted to be sung. It offers no musical variety, whereas its very beauties, and in particular those subtle harmonies which are secured by a proper attention to the structure of its quatrains and tercets, would not merely gain nothing, but would lose much by being set to music. Yet we can imagine even the sonnet chanted to some simple conventional melody, unobtrusive enough not to conceal its intellectual beauties nor that vein of reflective and pensive narration which links it to the epical order; and we must continue to regard the sonnet as essentially lyrical, notwithstanding its complexity and monotony. Not less than the song, the sonnet requires to consist of the spontaneous expression of a single intense emotion. What is true of the sonnet is true of the other traditional forms, some of which, as, for instance, the Rondeau, approach the song more closely, while others, as, for example, the grandiose Chant Royal, take their place on the further side of the sonnet, between the ode and the latter.

If in the divisions of lyrical poetry we find the other two classes occasionally present, the counterpart is still more true when we turn to a similar examination of epic and dramatic poetry. In the first case we possess an exquisite form, less successfully cultivated in England than in Italy, the Terza Rima, in which the lyrical and the epic forms co-exist to an almost equal degree. Here it is impossible to say whether the art of narrative or the art of song predominates. Even in the pure epic neither the lyrical nor the dramatic element is omitted. Whenever a burst of enthusiasm or passion seizes the narrator he passes without transition into lyric; whenever from describing his personages he proceeds to a record of their conversation, he suddenly transforms his epic into drama. Indeed, the rank of the various sections of the epical order of poetry may almost be determined by the opportunity they give for an admixture of the others. The Epistle is one of the least lyrical sections of all poetry; it may, however, contain an element of the dramatic. Satire, when it comprises no admixture of narrative, is apt to fall very low in the poetic scale. If its passion be enthusiastic and genuine it may attain to a certain lyrical afflatus; but there is little of the instinct of song in mere rage and disdain. Pure satire is commonly sustained solely by its executive ability, and is one of those species of literature which prove the necessity of giving to poetry a definition depending in the first instance not on its truth or beauty as 'a criticism of life,' but on its rhythmical structure.

Drama, as existing in modern Europe, has lost much of the external appearance of poetry. The distinction which admits a comedy in prose within the order of poetical literature and yet excludes a novel seems an arbitrary one. But it can be accounted for on traditional grounds. The novel has always been, from the days of the later Greeks, written in prose, and properly so, for it is independent of regulated form. Comedy, on the other hand, has but very lately, and still not completely, escaped from the bonds of verse. Rhythmical form is still largely used for tragedy, although the tendency in each of the great sections of drama is to dispense with a restraint which adds to the reader's pleasure, but in a much less degree to the spectator's. In other divisions of dramatic literature verse and even rime are still essential. In Opera, which is a combination of song with a conventional species of drama, both are necessary; and Pastoral imperatively demands for its graceful convention the ornament of metre. Dialogue, a dramatic form, may be combined even with an epical species as a medium for giving information or exhortation. Hastily looked at, however, drama appears in its modern aspects to be divorced more and more completely from the sister branches of poetry. It is therefore important to insist on the fact that the great poetical principle of unity in variety rules here as it does in those compositions which seem more completely under its sway. Without a lyrical element holding the parts of a drama together, balancing them, and supplying them with the necessary fire and harmony, the humblest play cannot maintain its existence. It is this more or less concealed dependence upon fixed laws of form which must always distinguish dramatic literature from the varieties of prose fiction. As long as it obeys these laws it holds its place in the order of poetry, although it may have abandoned its rhythmical shape. If it throws off these fortunate restraints it either perishes altogether or it becomes a mere variety of the prose novel.

In the incessant discussion which takes place as to the nature of poetry, the real aspect of the question is too frequently obscured by a confusion between Poetry, as a craft practised by artists, and the Poetical, as a metaphysical conception. The latter, which has been analysed with extraordinary minuteness by the Germans, and in particular by Goethe and by Hegel, is not necessarily combined with any of the external forms of poetical literature. This distinction, admirably laid down by Diotima in the *Symposium* of Plato, has been generally forgotten by those who have endeavoured to sentimentalise the art and to confuse our ideas of it by such vague and futile definitions as the well-known formula 'Poetry is impassioned truth.' It seems almost waste of words to point out that while the best poetry must be impassioned and must be true, in accordance with Aristotle's dictum that the superiority of poetry consists 'in its possessing a higher truth and a higher seriousness,' yet that no definition which confines itself to moral

or sentimental attributes can be adequate to distinguish an art which consists of the making of a certain definite thing in a certain definite form.

In short, and in spite of the extreme unwillingness of the metaphysician to acknowledge it, we must insist that the idea of poetry cannot be divorced from the incident of 'making,' whether we call it with Wordsworth 'impassioned expression' or employ the broader and simpler word 'execution.' Until the passion and the truth are fused into actual speech, and until that speech takes a rhythmical form, those elements may be as 'poetical' as you please, but they do not form poetry. None of the wild words of Mr Ruskin deserve an immortality of repudiation more thoroughly than the following phrase, which is always on the lips of those who write laxly and nebulously about the poetic art. 'No weight nor mass nor beauty of execution can outweigh one grain or fragment of thought,' says Mr Ruskin. If this were true, half of the noblest poetry in the world would cease to possess any value. Thought may and often does accompany the expression of the poetic art, but it is not essential to it in the sense in which Mr Ruskin uses the word, as an original act of the intellectual faculty. The few poets, indeed, who have aimed at producing 'chains of valuable thoughts' have rarely succeeded in doing more than giving tuneful expression to thought reflected from other and more ratiocinative minds. Even when a poet, such as Coleridge, has been eminently deductive and argumentative in his prose, he has generally been sensuous and simple in his verse. In the peculiar sense in which Mr Ruskin uses the word 'execution,' as directly distinguished from 'thought,' the work of the great poets has seldom possessed the latter quality in any notable degree.

It is desirable to define what is meant by 'execution,' for on this depends our whole conception of the practice of poetry as an art. It is not confined to an observance of the technical laws of this form of composition, to a correct and beautiful use of rhythm, of stanzaic form, of rime, and of that 'variety in unity' in which the charm of verse consists. All this is part of poetical execution, and an extremely important part. In most cases it may be said to be an indispensable part. But it is not all. Execution in poetry, as in the other fine arts, is the mechanical performance by which the effect desired is produced in the most perfect and most characteristic manner, so as in the happiest combination to illustrate the nature of the art itself and the individuality of the artist. As the medium in which the poet works is language, execution in his case is the arrangement of the best words in the best order, the best order being, in all but a few anomalous cases, a rhythmical one. The technical laws of verse, however, deal only with 'the best order.' There remain, as a part of execution, 'the best words.' This section of the definition covers all the intellectual propriety, the moral passion, the verbal felicity, the myriad charms and graces, of which 'the best order' is but the vehicle. It is part of a poet's technical work, part of his business as a 'maker,' to produce this manifold perfection of regulated language, and all these beauties of expression and feeling cannot be rudely divided from that 'execution' of which they are an inherent feature. The bad poet may have the intellect of Locke or of Spinoza; he will learn by the total neglect of his verses that in poetry no weight nor mass of thought can outweigh one grain of executive skill.

It would, nevertheless, be a grave error to insist so emphatically on the importance of the outward form of poetry as to encourage neglect of its inward character. In a definition of poetry it has been deemed needful to dwell here on the fact that it is primarily an art and subjected to definite laws. But, as Joubert has said, 'the lyre is a winged instrument,' and the closest attention to its constructive mechanism will not give it the power of flight if inspiration be lacking. The vivid pleasure produced by the best poetry is due in large measure to the merits of its execution—its music, the splendour of its images, the harmony and felicity of its arrangement of language. But there is something beyond and above this 'complex feeling of delight;' there is a spiritual emotion which is the spontaneous result of close attention to great poetry, and which is created in the soul only by verse that is of the highest value. This emotion is founded on the Aristotelian qualities of 'the higher truth' and 'the higher seriousness,' and is inseparable from, though not to be confounded with, the mere physical delight in lovely sounds and marshalled groups of images. In this exquisite passion of poetry there is something supernatural, which evades analysis. It combines the experience of life with the hope of immortality, and fuses what has been felt and witnessed into what has only been, and can only be, imagined. The literature of all countries and of all ages has proved that this subtle and divine emotion is produced in its most direct form by the art of language rhythmically arranged, and to this art is given the name of Poetry.

The prose fragment called the *Poetics* of Aristotle is the earliest and most important treatise on the art of poetry which has come down to us from antiquity. What is commonly known as Horace's 'Art of Poetry' gives us the views of an admirable Latin writer on verse and on the poet. In 1527 Vida published his Latin poem, *Ars Poetica*, which exercised a great authority, and was by many students preferred to Horace. Of more modern interest is Scaliger's treatise, *Poetices Libri Septem* (1561). The first manual of modern Italian prosody was Girolamo Muzio's *Arte Poetica* (1551). In the England of Elizabeth we have three important treatises on the art, *An Apology for Poetry* (1595), by Sir Philip Sidney; *A Discourse of English Poetry* (1586), by W. Webbe; and *The Art of English Poesy* (1589), by George Puttenham. In France the first important treatise on the subject was the *Art Poëtique Français* (1604), by Vauquelin de la Fresnaye. Nicolas Boileau, 'the Lawgiver of Parnassus,' wrote an *Art Poétique*. Among French works of the 18th century the most important are *Traité de la Prosodie Française* (1736), by Olivet, and *Réflexions sur la Poésie* (1752), by Louis Racine. Dryden's *Essay on Dramatic Poetry* belongs to 1669. Among modern works must be cited that portion of Hegel's *Æsthetik*. Guest's *History of English Rhythms* (1838; new ed. 1882) remains the best authority on British prosody, while the *Petit Traité de Poésie Française* is greatly to be recommended.

See also in this work ENGLISH LITERATURE, the sections on literature in the articles on the several countries, and the articles BALLAD, BLANK VERSE, DIDACTIC POETRY, DRAMA, EPIC POETRY, HYMN, LYRIC, METRE, ODE, PASTORAL POETRY, RHYME, SATIRE, SONNET. There are separate articles on all the best-known poets, including the following:

GREEK.

Homer (about 900).
Alcæus (600).
Sappho (630–570 B.C.).
Æschylus (525–461 B.C.).
Pindar (522–422 B.C.).
Sophocles (495–405 B.C.).
Euripides (480–406 B.C.).
Aristophanes (448–388 B.C.).
Menander (342–291 B.C.).

LATIN.

Plautus (254–184 B.C.).
Terence (185–159 B.C.).
Lucretius (98?–55 B.C.).
Catullus (87–54 B.C.).
Virgil (70–19 B.C.).
Horace (65–8 B.C.).

LATIN.

Tibullus (54–18 B.C.).
Propertius (50–16 B.C.).
Ovid (43 B.C.–18 A.D.).
Lucan (39–65 A.D.).
Martial (41–104 A.D.).
Juvenal (55–130? A.D.).

ITALIAN.

Dante (1265–1321).
Petrarch (1304–74).
Boiardo (1434–94).
Ariosto (1474–1533).
Tasso (1493–1569).
Goldoni (1707–93).
Alfieri (1749–1803).
Manzoni (1785–1873).
Leopardi (1798–1837).

French.
Chanson de Roland (11th c.).
Villon (1431–61).
Marot (1496–1544).
Ronsard (1524–85).
Malherbe (1555–1628).
Regnier (1573–1613).
Corneille (1606–84).
Lafontaine (1621–95).
Molière (1622–73).
Boileau (1636–1711).
Racine (1639–99).
Rousseau, J. B. (1670–1741).
Voltaire (1694–1778).
A. de Chénier (1762–94).
Béranger (1780–1857).
Lamartine (1790–1869).
Hugo (1802–85).
De Musset (1810–57).
Gautier (1811–72).
Leconte de Lisle (1818–94).
Sully-Prudhomme (b. 1839).
Coppée (b. 1842).

Spanish.
The Cid (12th century).
Lope de Vega (1562–1635).
Calderon (1600–81).

Portuguese.
Camoens (1524–80).

Russian.
Pushkin (1799–1837).
Lermontoff (1814–41).

Scandinavian.

Holberg (1684–1754).
Bellman (1740–95).
Ewald (1743–81).
Baggesen (1764–1826).
Œhlenschläger (1779–1850).
Tegner (1782–1846).
Geijer (1783–1847).
Grundtvig (1783–1872).
Heiberg (1791–1860).
Runeberg (1804–77).
Ibsen (b. 1828).
Bjornson (b. 1832).

Dutch.
Vondel (1587–1679).
Bilderdijk (1756–1831).
Lennep (1802–68).
Beets (b. 1814).

German.
Nibelungen (12th century).
Reineke Fuchs (13th century).
Sachs (1494–1576).
Klopstock (1724–1803).
Lessing (1729–81).
Wieland (1733–1813).
Herder (1744–1803).
Goethe (1749–1832).
Schiller (1759–1805).
Arndt (1769–1860).
Uhland (1787–1862).
Korner (1791–1813).
Heine (1799–1856).
Gutzkow (1811–78).
Hebbel (1813–63).

British.
Cædmon (d. 680).
Beowulf (8th century).

British.
Barbour (1316–95).
Langland (b. about 1332).
Chaucer (1340–1400).
Lyndsay (15th century).
James I. (1406–37).
Dunbar (1460–1530).
Gavin Douglas (1474–1522).
Spenser (1553–99).
Sir P. Sidney (1554–86).
Lodge (1556–1625).
Drayton (1563–1631).
Marlowe (1564–93).
Shakespeare (1564–1616).
Dekker (1570–1641).
Donne (1573–1631).
Jonson (1573–1637).
Marston (1575–1634).
Fletcher (1579–1625).
Massinger (1583–1638–39).
Beaumont (1584–1616).
Drummond (1585–1649).
Ford (1586–1639).
Carew (1589–1639).
Herrick (1591–1674).
Herbert (1593–1633).
Waller (1605–87).
Milton (1608–74).
Suckling (1609–41).
Butler (1612–80).
Cowley (1618–67).
Marvell (1621–78).
H. Vaughan (1621–95).
Dryden (1631–1700).
Otway (1651–85).
Prior (1664–1721).
Young (1684–1765).
Gay (1685–1732).
Pope (1688–1744).
Thomson (1700–48).
Gray (1716–71).
Collins (1721–59).
Goldsmith (1728–74).
Cowper (1731–1800).
Chatterton (1752–70).
Crabbe (1754–1832).
Blake (1757–1827).
Burns (1759–96).
Rogers (1763–1855).
Wordsworth (1770–1850).
Scott (1771–1832).
Coleridge (1772–1834).
Southey (1774–1843).
Landor (1775–1864).
Campbell (1777–1844).
Moore (1779–1852).
Leigh Hunt (1784–1859).
Byron (1788–1824).
Shelley (1792–1822).
Keats (1795–1821).
Hood (1799–1845).
Mrs Browning (1806–61).
Tennyson (1809–92).
Browning (1812–89).
Clough (1819–61).
Arnold (1822–88).
Rossetti (1828–82).
Christina Rossetti (1830–94).
W. Morris (1834–96).
Swinburne (b. 1837).

American.
Bryant (1794–1878).
Emerson (1803–82).
Whittier (1807–92).
Longfellow (1807–82).
Holmes (1809–94).
Poe (1809–49).
Lowell (1819–90).
Whitman (1819–92).

Pogge (*Agonus cataphractus*), a small fish, not uncommon on British coasts, also known as *Armed Bullhead*, *Lyrie*, *Pluck*, and *Noble*. It is related to the Bullhead (q.v.). The body, about 6 inches long, is cuirassed by large scales; the head is very broad, and the mouth is very small. Notwithstanding its uncouth appearance, it is good to eat.

Poggendorf, Johann Christian, a German physicist, was born at Hamburg, 29th December 1796. He studied pharmacy, chemistry, and physics, and was professor of Physics at Berlin from 1834 till his death. In 1839 he was made a member of the Berlin Academy of Sciences. His chief discoveries were in connection with electricity and galvanism; he also invented a multiplying galvanometer for measuring the calorific action of currents. From 1824 he edited the *Annalen der Physik und Chimie*, better known as *Poggendorfs Annalen*, an important organ for the history of the physical sciences. Besides helping Liebig and Wöhler to prepare the *Dictionnaire de Chimie* (1837–51), he wrote *Lebenslinien zu einer Geschichte der exakten Wissenschaften* (1853), *Biographisch-litterarisches Wörterbuch zur Geschichte der exakten Wissenschaften* (2 vols. 1857–63), and *Geschichte der Physik* (1879). He died 24th January 1877.

Poggio Bracciolini, Gian Francesco, a famous Italian humanist, was born in 1380 at Terranova in Florence. He studied Latin under John of Ravenna, and Greek under Manuel Chrysoloras, and early gained the notice of the Florentine scholars for his skill in copying MSS. About 1402 he became a secretary to the Roman curia; but, though the fifty years of his service covered a period of remarkable importance, he seems to have taken no interest whatever in the movement of church affairs, but to have been devoted heart and soul to the resuscitation of classical learning. In the course of his duties at the Council of Constance (1414–18) he explored the Swiss and Swabian convents for MSS., and later in his wider travels to England and elsewhere he never lost sight of the dearest interest of his life. He was able to recover MSS. of Quintilian, Ammianus Marcellinus, Lucretius, Silius Italicus, Vitruvius, and many other Roman authors. About 1452 he retired to Florence, and next year succeeded Carlo Aretino as historiographer to the republic. Here he died in 1459. His writings include *Letters* (best ed. by Tonelli, 3 vols. Flor. 1832–61); moral essays *On Nobility*, *On the Infelicity of Princes*, *On Marriage in Old Age* (he himself in 1435 took to wife a girl of eighteen), and the like; a rhetorical Latin *History of Florence*, in imitation of Livy; a series of unclean and unscrupulous polemical invectives against contemporaries, especially Filelfo and Valla; and a poor translation into Latin of Xenophon's *Cyropædia*. But his most famous book is the *Liber Facetiarum*, a collection of humorous and not too decent stories and jests, written in fair Latin, and full of merry raillery at the expense of the monks and secular clergy. The book has some importance in the study of the diffusion and development of folk-tales, and here Poggio takes a place with Straparola, Morlini, Boccaccio, Sacchetti, and Bandello, between the later *conteurs* who have borrowed or worked up their stories on the one hand, and such earlier storehouses as the *Exempla*, the *Disciplina Clericalis*, the *Aurea Legenda*, the *Gesta Romanorum*, and the *Fabliaux* on the other. A good edition (Fr. trans. and text) is that of Isidore Lisieux (Paris, 1878).

See the Life by Dr Shepherd; also Voigt's *Wiederbelebung des classischen Alterthums*, and Symonds' *Renaissance in Italy*.

Poinding (same root as Eng. *pound*), in the law of Scotland, means the seizing and selling of a debtor's goods under process of law, or under the warrant of a heritable security, in order to pay the debt. It is either real or personal. Real poinding is the attaching of goods or movables on the land over which some heritable security exists. It is one mode in which heritable security is made effectual. Thus, the superior of lands can poind the ground to obtain payment of his feu-duties; and the holder of a heritable bond can do the same in order to recover his debt. Personal poinding is the mode in which a decree of the court is made effectual by the messenger or bailiff seizing the movables of the debtor. It may not proceed until the debtor has been charged to pay the debt and the days of charge have elapsed. The debtor's

goods being pounded, they are appraised or valued, and the messenger reports his execution to the sheriff, or other judge ordinary, who grants warrant to sell the goods by public roup after advertisements. The net amount of the sale is paid over to the creditor, or, if no purchaser bid for them, they are delivered to the creditor at the appraised value. There is also another kind of pounding, called a pounding of stray cattle, which takes place whenever the cattle of a stranger trespass on lands, in which case the owner or occupier of the lands can seize them at his own hand, without judicial warrant, and keep them as a security until the damage done by the cattle is paid to the owner of the land. The pounder must, however, take care to keep the cattle in a proper place, and feed them. In England the word pounding is not used, the corresponding term being Distress (q.v.).

Poinsettia, a name given to the Mexican shrub *Euphorbia pulcherrima*, introduced into the horticulture of other lands by Joel Roberts Poinsett (1779-1851), U.S. minister to Mexico. It is remarkable for the large and conspicuous vermilion bracts below its yellowish flowers.

Point-a-Pitre, the principal town and port, though not the capital, of Guadeloupe (q.v.), on the south-west side of Grande-Terre. It is fortified, and has some sugar-boiling. Pop. 17,000.

Point de Galle. See GALLE.

Pointed Architecture. See GOTHIC.

Pointer, a breed introduced from Spain about the middle of the 18th century. The Spanish pointer was a larger and much slower dog than the modern English pointer, rather wanting in stamina, and inclined to 'knock up' with a hard day's work; but, if not hurried, was possessed of wonderful nose and powers of scent. As shooting became more common, and guns approached nearer to perfection, the Spanish pointer was found to be too slow and soft. With the object of removing these defects, crosses with the greyhound to improve the speed, and with the bulldog to get courage, were tried, but with little success, until about the beginning of the 19th century the well-known Colonel Thornton tried a cross with the lighter variety of foxhound. He soon succeeded in breeding a light and active dog, capable of ranging at a fast pace for a considerable time,

Pointer Standing at Game.

and though possibly not with the nose of the old Spanish pointer, yet with sufficient for the purpose. Other breeders followed suit, and a distinct strain known as the English Pointer was soon established. By careful selection the hound tendency to hunt a foot-scent was eradicated, or nearly so, while some of the speed and staying powers of the hound were retained. The act of 'pointing' when the game is first scented was at first carefully taught, but gradually became instinctive. until now well-bred puppies of a few months old may be seen pointing at any object which excites them. In general appearance the pointer somewhat resembles the foxhound, though he is a lighter and more active dog, with a finer coat. The head of the pointer should be fairly large, with an intelligent expression; a small eye or too much lip greatly detracts from the appearance. The shoulders should be sloping and powerful, as the dog has often to stop suddenly on a 'point' when at full speed. The body should be built on graceful and racing lines, chest not too wide, but very deep, feet round and compact. Liver and white, and lemon and white, are the popular colours, as they are easily seen in heather or turnips, but whole black or liver has many admirers. Owing to the changed conditions of agriculture, the pointer is not now used so extensively for partridge shooting, but is still used for grouse. In hot weather, where water is scarce, the pointer has a great advantage over the setter, but succumbs sooner to cold and wet than the heavy coated setter. As the pointer is seldom kept as a companion, his intelligence is not of a high order, but he is easily kept in command, and is generally good-tempered.

Poison is commonly defined to be a substance which, when administered in small quantity, is capable of acting deleteriously on the body; but this definition is obviously too restricted, for it would exclude numerous substances which are only poisonous when administered in large doses, as the salts of lead, antimony, &c.; hence the quantity required to kill must not enter into the definition. A good practical definition of a poison is 'any substance or matter which, when introduced into the body in any way, can destroy life by its own inherent qualities without acting mechanically.' This definition includes poisonous solids, liquids, and gases of definite chemical composition—the products of decomposition or of bacterial organisms, and the virus of contagious diseases. The last mentioned produce the symptoms of the various infectious and contagious diseases, and are not included in treatises on poisons. The others are classified sometimes according to their source, as mineral, vegetable, and animal; or more conveniently according to their action, as *Irritants*, *Narcotics*, and *Narcotico-irritants*.

The *Irritants*, when taken in ordinary doses, speedily occasion intense vomiting and purging and severe abdominal pain. They act chiefly on the stomach and intestines, which they irritate, inflame, and frequently corrode, and may thus occasion ulceration, perforation, or gangrene. Amongst those which possess corrosive properties are the strong mineral acids, caustic alkalies, corrosive sublimate, &c.; whilst among the pure irritants which exert no destructive chemical action on the tissues with which they come in contact may be mentioned cantharides. The *Narcotics* act specially on the brain and spinal cord. Amongst their most common symptoms are giddiness, headache, obscurity of sight or double vision, stupor, loss of power of the voluntary muscles, convulsions, and, finally, complete coma. These poisons have no acrid, burning taste, nor do they usually give rise to vomiting or diarrhœa, and, excepting a slight fullness of the cerebral vessels, they leave no well-marked post-mortem appearance. They are few in number, and none of them belong to the mineral kingdom. The *Narcotico-irritants* have, as their name implies, a mixed action. At varying periods after they have been swallowed they give rise to vomiting and purging, like irritants, and sooner or later produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. As familiar examples we may

point to monkshood, tobacco, and poisonous mushrooms. Sometimes the more violent of the poisons here classed as irritants are made into a separate group—*Corrosives;* the narcotics are put under the head *Neurotics;* and the *gaseous* poisons are treated as a separate class.

Under the head of *Irritant Poisons* may be included (1) Mineral Acids, as sulphuric, nitric, and hydrochloric acids; vegetable acids, and some of their salts, as oxalic acid, binoxalate of potash, and tartaric acid (in doses of half an ounce or more); the alkalies, as pearl-ash (carbonate of potash), soap lees (carbonate of soda), ammonia and its sesquicarbonate in strong solution; and metallic compounds, as white arsenic (arsenious acid), yellow arsenic (orpiment), corrosive sublimate, pernitrate and other salts of mercury, acetate of lead (sugar of lead) in doses of an ounce and upwards, sulphate of copper (blue vitriol), subacetate of copper (verdigris), arsenite of copper (commonly known as *Scheele's green* or *emerald green*, which has been employed under the name of *extract of spinach* for colouring confectionery), tartarated antimony, chloride of antimony (butter of antimony), chloride of zinc (Sir W. Burnett's Fluid), nitrate of silver (lunar caustic), sulphate of iron (copperas or green vitriol), and bichromate of potash; (2) Vegetable Substances—viz. colocynth and gamboge in large doses, savin, croton-oil, elaterium, &c.; and (3) Animal Substances, such as cantharides, to which must be added the occasional cases in which sausages, and certain fish and molluscs, usually quite innocuous, act as irritant poisons. The *Narcotic Poisons* include opium, hydrocyanic (or prussic) acid, cyanide of potassium, henbane, alcohol, ether, chloral, and chloroform. The *Narcotico-irritant Poisons* include nux vomica, meadow saffron (Colchicum), white hellebore, foxglove, common hemlock, water hemlock (*Cicuta virosa*), hemlock water-dropwort (*Œnanthe crocata*), fool's parsley, thorn-apple, monkshood or aconite, deadly nightshade, tobacco, Indian tobacco (*Lobelia inflata*), the bark and seeds of the common laburnum, the berries and leaves of the yew-tree, and certain kinds of fungi.

The cases in which there are antidotes qualified to neutralise chemically the action of the poison are few in number. For the *mineral acids* chalk or magnesia in water must be used, with the view of neutralising them, after which milk should be given freely. The *alkalies and their carbonates* must be neutralised by vinegar and water, or lemon-juice mixed with water, after which milk should be given. For *oxalic acid* the antidote is chalk or magnesia in water, by which an insoluble oxalate of lime or magnesia is formed. For *arsenic* the hydrated peroxide of iron has been regarded as an antidote, but its efficacy is doubtful. Vomiting should be excited by the administration of a scruple of sulphate of zinc in warm water, and, after the stomach has been well cleared out, demulcent fluids, such as flour and water or milk, should be given. *Corrosive sublimate* combines with albumen (white of egg), and forms an insoluble inert mass; *nitrate of silver* is neutralised by chloride of sodium (common salt) dissolved in water; *tartarated antimony* is to a great degree rendered inert by the administration of decoction of bark or gall-nuts; and *acetate of lead* is rendered inert by the administration of sulphate of magnesia, which converts it into an insoluble sulphate of lead. In all cases of suspected poisoning, in which the nature of the poison is not known, the safest course is at once to produce vomiting by sulphate of zinc, or in its absence by a dessert-spoonful of flour of mustard suspended in tepid water, and to continue the vomiting till all the contents of the stomach are discharged, after which milk should be given freely.

Most of the known gases have a poisonous action when inhaled into the lungs; in these cases death may be due simply to suffocation or to a specific action of the gas. *Carbonic Acid* (q.v.), although seldom employed as an instrument of murder, is a frequent cause of accidental death, and in France is a common means of self-destruction. It is established by numerous experiments that air containing more than *one-tenth* of its volume of carbonic acid will, if inhaled, destroy life in man and the higher animals: when diluted with two or more volumes of air it can be breathed, and produces symptoms of vertigo and somnolency, and so great a loss of muscular power that the individual, if in an erect or sitting position, falls as if struck to the ground. The respiration, which at first is difficult and stertorous, becomes suspended. The action of the heart is at first violent, but soon ceases, sensibility is lost, and the person now falls into a comatose or death-like state. Those who have been resuscitated usually feel pain in the head and general soreness of the body for some days, and in a few severe cases paralysis of the muscles of the face has remained. The patient must, of course, be at once removed from the poisonous atmosphere, after which artificial respiration should be had recourse to. If the skin is warm cold water may be poured on the head and spine; while if the surface be cold a warm bath should be employed. When respiration is re-established venesection will often relieve the congestion of the vessels of the brain. The inhalation of oxygen gas is said to have been of service in these cases. *Carbonic oxide* is also an active poison, and is present in coal-gas and in charcoal fumes. Both carbonic acid and carbonic oxide act as powerful narcotics. The fatal power of ordinary coal-gas as an asphyxiant and irritant is probably due to the carbonic oxide present; the post-mortem appearances are very similar in cases of poisoning by coal-gas and by carbonic oxide. *Sulphuretted hydrogen*, which occurs abundantly in foul drains, sewers, cesspools, &c., is a gaseous poison whose effects are often noticed. Nothing certain is known of the smallest proportion of this gas required to destroy human life; but air containing only $\frac{1}{800}$th of its volume of this gas will destroy a dog; and when the gas exists in the proportion of $\frac{1}{250}$th it will kill a horse. During the construction of the Thames Tunnel the men engaged in the work suffered severely from the presence of this gas, which was probably derived from the action of the water on the iron pyrites in the clay, and which issued in sudden bursts from the walls. By respiring this atmosphere the strongest and most robust men were in the course of a few months reduced to an extreme state of exhaustion, and several died. The symptoms with which they were first affected were giddiness, sickness, and general debility; they became emaciated, and fell into a state of low fever accompanied by delirium. In this case the dilution was extreme; when the gas is breathed in a more concentrated form the person speedily falls, apparently lifeless. It appears to act as a narcotic poison when concentrated, but like a narcotico-irritant when much diluted with air. The action of the vapour of *sulphide of ammonium*, which is also commonly present in cesspools, &c., is probably much the same as that of sulphuretted hydrogen. Many of the gases which are only found as products of the laboratory are in the highest degree poisonous, as arseniuretted hydrogen; but as few persons run the risk of inspiring them it is unnecessary to enter into details.

In point of Law, the use of poison to kill or injure a human being or certain animals renders the poisoner amenable to the criminal courts. With regard to the sale of poisons, the legislature found

it necessary to put some restrictions on one description—viz. arsenic—in order to prevent persons obtaining it with facility, and in such a manner as to avoid detection. The 14 and 15 Vict. chap. 13, requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, and later acts apply this rule to other poisons. It is not to be sold to one who is unknown to the vendor unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of ½ oz. of soot or indigo to the lb. All the boxes, bottles, &c. must be labelled 'Poison.' Those who offend as to arsenic incur a penalty of £20; but in ordinary prescriptions poisons may be used in the ordinary way by duly qualified medical practitioners. As to the restriction on the sale of other poisons, see CHEMISTS AND DRUGGISTS. The offences committed by those who administer poisons to mankind are as follow: Whoever causes death by poison commits murder, for the means are immaterial if the death was caused by such means with a felonious intent. Where death is not caused, nevertheless whoever administers poison, or causes it to be administered to any person, with intent to commit murder is guilty of felony, and is liable to penal servitude for life, or for not less than three years. Moreover, whoever attempts to administer poison, or other destructive thing, to any person with intent to commit murder is guilty of felony, and is punishable in the same way. These offences are committed whether the poison administered or attempted to be administered, does injury or not; and it is a sufficient committing of the offence if the poison is put in such a place that a party was likely, and was intended to take it. Moreover, even though murder was not intended, but merely an intent to endanger life or inflict grievous bodily harm, still the offence is felony, and is punishable by penal servitude varying from three to ten years. There is also a similar punishment for the attempt to administer any stupefying drug. Not only is it a crime to administer or attempt to administer poison to human beings, but if cattle are maliciously killed by poison the offence is felony, punishable by penal servitude of from three to fourteen years. So to kill by poison any dog, bird, beast, or other animal, ordinarily kept in a state of confinement, is an offence punishable by justices of the peace with imprisonment for six months, or a fine of £20 over and above the injury done. If any person lay poison on lands to kill game he incurs a penalty of £10. Moreover, by the Act 26 and 27 Vict. chap. 113, extending to the United Kingdom, whoever sells or offers to sell poisoned grain, seed, or meal incurs a penalty of £10. Whoever sows, lays, or puts on ground such poisoned grain incurs a like penalty. The use of poisoned flesh is also prohibited. But the sale or use of any solution, material, or ingredient for dressing, protecting, or preparing any grain or seed for agricultural use only, if used *bonâ fide*, is not interfered with.

SECRET POISONING is a mode of taking away life by poisons so slow in their operation that the gradual sinking of the victims under their influence closely resembled the effects of disease or the ordinary decay of nature. It has been practised in all ages, and several undoubted and numerous supposed instances of it are mentioned by Greek and Roman writers. The prevailing ignorance of pathology and chemistry enabled crimes to be carried out with impunity with poisons which would be readily detected at the present day; and for similar reasons many deaths were ascribed to poison that were doubtless due to natural causes. It is impossible to attach much credence to stories such as that Henry VI. was killed by a pair of poisoned gloves, or that victims were simply got rid of by inducing them to smell a poisoned rose. And it is wholly incredible that in pre-scientific days treacherous friends and hidden enemies had access to secret and mysterious methods of poisoning beyond the power of detection that are happily denied to scientific investigators in days when we are acquainted with ten times as many and ten times as subtle poisons. In secret poisoning various preparations of arsenic seem once to have been most frequently used. In the 17th century this atrocious practice became of specially frequent occurrence; and from this time it rapidly increased, spread over western Europe like an epidemic, and became gradually a regular branch of education among those who professed a knowledge of chemistry, magic, or astrology. These persons regarded the knowledge of the mode of preparing secret poisons as of the highest importance, and many of them realised large sums by the sale of their preparations, and occasionally of the secret of their composition. It was in Italy and France that this art was chiefly practised and brought to the highest perfection; but it seems also to have prevailed in England to a considerable extent, for in 1531 the poisoning of seventeen persons, two of whom died, by the Bishop of Rochester's cook led to the passing of an act which declared the employment of secret poisons to be high-treason, and sentenced those who were found guilty of it to be boiled to death. This act was repealed in 1547.

The only undoubted instance of this crime which appears prominently in English history is the murder of Sir Thomas Overbury (q.v.) by Viscount Rochester (the favourite minion of James I.) and his wife, the divorced Countess of Essex. Prince Henry was falsely supposed to have been poisoned by his father, James I. (1612); and James's own death was similarly ascribed to nefarious practices on the part of Buckingham, nay, even of Charles I. (Milton). Undoubtedly such was the popular impression at the time, for Dr Lamb, a conjuror and quack, who was believed to have furnished Buckingham with the poisons, was seized by the angry populace in Wood Street, Cheapside, London, and beaten and stoned to death. But it was in Italy that this mode of poisoning was most prevalent. There, judging from the writings of various authors, it seems to have been looked upon as a not unjustifiable proceeding to get rid of a rival or enemy by poison; and from the time of the Lombard invasion down to the 17th century Italian history teems with instances which sufficiently show that poison was both the favourite weapon of the oppressor and the protection or revenge of the oppressed. The Borgias (q.v.) are generally singled out and held up to the horror and detestation of mankind; but as far as their poisonings are concerned they merely employed this method of destroying their adversaries a little more frequently than their neighbours. To show the popular feeling on this subject we may instance the case mentioned in the *Mémoires* of Henry II., fifth Duke of Guise, of a soldier who was requested to rid the Duke of Gennaro Annese, one of his opponents in Naples. *Assassination* was the mode proposed to the soldier, but he shrank with horror from the suggestion, stating at the same time that he was quite willing to *poison* Annese. It was shortly after the date of this story (1648) that secret poisoning became so frequent; and the Catholic clergy, despite the rules of the confessional, felt themselves bound to acquaint Pope Alexander VII. with the extent of the practice. On investigation it was found that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages

were speedily dissolved by the sickness and death of the husband; and further inquiries resulted in the discovery of a secret society of young matrons which met at the house of an old hag, by name Hieronyma Spara, a reputed witch and fortune-teller, who supplied those of them who wished to resent the infidelities of their husbands with a slow poison, clear, tasteless, and limpid, and of strength sufficient to destroy life in the course of a day, week, month, or number of months, as the purchaser preferred. The ladies of Rome had been long acquainted with the 'wonderful elixir' compounded by La Spara; but they kept the secret so well, and made such effectual use of their knowledge, that it was only after several years, during which a large number of unsuspected victims had perished, and even then through a cunning artifice of the police, that the whole proceedings were brought to light. La Spara and thirteen of her companions were hanged, a large number of the culprits were whipped half-naked through the streets of Rome, and some of the highest rank suffered fines and banishment. About half a century afterwards the discovery was made of a similar organisation at Naples, headed by an old woman of threescore and ten named Toffania, who manufactured a poison similar to that of La Spara, and sold it extensively in Naples under the name of *acquetta*, and even sent it to all parts of Italy under the name of 'Manna of St Nicola of Bari,' giving it the same name as the renowned miraculous oil of St Nicola to elude discovery. This poison, now best known as the 'Acqua Tofana' or 'Acqua di Perugia,' is said by Hahnemann to have been compounded of arsenical neutral salts; while Garelli states that it was crystallised arsenic dissolved in a large quantity of water; but both agree that it produced its effect almost imperceptibly by gradually weakening the appetite and respiratory organs. After having directly or indirectly caused the death of more than 600 persons, Toffania was at length seized, tried, and strangled in 1719. From this time the mania for secret poisoning gradually died away in Italy.

Catharine de' Medici has been frequently charged with wholesale poisoning, and in 1558 four of the Scottish commissioners who had been present at Queen Mary's marriage to the Dauphin were poisoned, it was believed, at Dieppe. But it was about the middle of the 17th century that this horrible practice seems to have become most prevalent in France. Here, too, the agents were married women, and their husbands the victims; and, as in Italy, the extent to which the practice was carried was first made known by the clergy. The government, acting on the information thus obtained, seized and imprisoned in the Bastille two Italians named Exili and Glaser, who were suspected of having been the manufacturers and vendors of the poisons. Glaser died in prison; but Exili, becoming acquainted with another prisoner named St Croix, communicated to him his secret, which the latter made considerable use of after his release, compounding in particular the poison known as 'succession powder,' which subsequently became so celebrated. It was the same St Croix who played such a prominent part in the tragical history of the Marquise de Brinvilliers (q.v.). Penautier, the treasurer of the province of Languedoc, and the Cardinal de Bonzy were both pupils of St Croix, and managed, the one to pave the way for his own advancement, and the other to rid himself of his numerous creditors by the administration of poison; but the great influence of these men and the want of direct evidence barred all proceedings against them. Secret poisoning now became fashionable; the passions of jealousy, revenge, avarice, and even petty spite were all satisfied in the same way, and as a necessary consequence other offences decreased in proportion. The prisons teemed with suspected criminals, and the 'Chambre Ardente' was instituted for the special purpose of trying these offenders. In Paris this trade was chiefly in the hands of two women named Lavoisin and Lavigoreux, who combined with the ostensible occupation of midwife that of fortune-teller, and foretold to wives the decease of their husbands, to needy heirs that of their rich relatives, taking care at the same time to be instrumental in fulfilling their own predictions. Their houses were frequented by numbers of all classes, both from Paris and the provinces, among whom were the celebrated Marshal de Luxembourg (q.v.), the Duchess de Bouillon, and the Countess de Soissons; the two former of these, however, went merely from curiosity. Lavoisin and her confederate were at last discovered, tried, condemned, and burned alive in the Place de Grève, 22d February 1680; and from thirty to fifty of their accomplices were hanged in various cities of France. So common had this atrocious practice been that Madame de Sévigné, in one of her letters, expresses a fear lest the terms 'Frenchman' and 'poisoner' should become synonymous. For two years after the execution of the two Parisian poisoners the crime continued to be largely committed, being fostered by the impunity with which offenders of high rank were allowed to escape; and it was not till more than a hundred persons had died at the stake or on the gallows that the government succeeded in suppressing it. The mania for secret poisoning has not since been revived to the same extent, though isolated instances of its practice have occasionally been discovered, particularly in Hungary, where, within the last half of the 19th century, very extraordinary disclosures have at different times been made of the prevalence of this frightful crime among the peasant women. During the times of slavery the Obeah men among the negroes in the West Indies were credited with being expert poisoners. They used vegetable poisons obtained from plants, and there can be no doubt were often instrumental in getting rid of tyrannical or otherwise objectionable masters. In Britain famous poisoning trials have been those of W. Palmer (three victims, 1856), Madeleine Smith ('not proven,' 1857), E. W. Pritchard, M.D. (two victims, 1865), Mary Ann Cotton (sixteen victims, 1872), G. H. Lamson, M.D. (1882), P. Cross, M.D. (1887), and Mrs Maybrick (1889).

Winter Blyth (1883; 2d ed. 1886), and J. D. Mann (1893).—For the Poison Ivy, see SUMACH.

Poisson. SIMEON-DENIS, was born at Pithiviers, in Loiret, 21st June 1781; and received into the École Polytechnique in 1798, attracted the notice of Lagrange and Laplace, both of whom anticipated for him a brilliant career. In 1802 he became a professor in the Polytechnique; in 1808 a member of the Bureau des Longitudes; in 1809 professor in the Faculty of Sciences; member of the Institute in 1812, &c.; and this list of distinctions was crowned in 1837 by his elevation to the dignity of a peer of France. He died 25th April 1840. Poisson's

whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 Memoirs, inserted in the publications of the École Polytechnique, of the Academy of Sciences, and other scientific journals. Of the separate treatises published by Poisson the best known is the *Traité de Mécanique* (2 vols. 1833); others were on capillary action, the mathematical theory of heat, the motion of projectiles, and, lastly, the celebrated work *Sur l'Invariabilité des moyens Mouvements des grands Axes Planétaires.* Poisson is fairly considered one of the chief founders of the science of mathematical physics.

Poitiers, the capital of the French department of Vienne, occupies the summit and slopes of a little eminence, round whose base flow the Clain and the Boivre, 61 miles SSW. of Tours. Before the revolution it had an immense number of religious edifices, which even yet are sufficiently numerous. The most interesting are the little Temple de St Jean, originally a baptistery of the 6th or 7th century; the abbey church of St Radegonde, with the saint's cenotaph, much visited by pilgrims; and the noble cathedral of St Pierre (1161–15th century), in which, or in the older edifice that occupied its site, twenty-three councils were held —the first in the 4th, and the last in the 15th century. Other edifices are the Palais-de-Justice (the palace formerly of the Counts of Poitou) and the Hôtel-de-Ville (1876). A university, founded by Charles VII. in 1431, is now represented by a school of law, with faculties also of science and literature. There are besides a public library of 30,000 volumes and 400 MSS., a museum, and several learned societies, including one for studying the antiquities of western France (1834). Pop. (1872) 28,247; (1891) 34,374. Poitiers, the *Limonum* of the Romans, derives its present name (earlier *Poictiers*) from the Pictavi or Pictones. In and around it are numerous Celtic and Roman remains, a dolmen, baths, some fragments of a huge amphitheatre, &c.; and here in 1882 the remains of a whole Gallo-Roman town were discovered, with temple, baths, and streets, spread over 14 acres. In the vicinity Alaric II., the Visigoth, was defeated and slain by Clovis in 507; and somewhere between Poitiers and Tours Charles Martel won his great victory in 732 over the Saracens under Abd-ur-Rahmân. Later still (on 19th September 1356), at a spot 5 miles north of Poitiers, Edward the Black Prince, with some 12,000 or 14,000 Englishmen and Gascons, defeated 60,000 of the troops of King John of France, killing 11,000 and taking more than 2000 prisoners, among these the monarch himself and one of his sons. St Hilary (q.v.) was the first bishop of Poitiers, which long was capital of the province of Poitou. From this town the ancient family took its name to which Diana of Poitiers (q.v.) belonged.

Poitou, a former province of south-western France, coincident with the present departments of Deux Sèvres, Vendée, and Vienne. It was divided into Upper and Lower Poitou, and had for its capital Poitiers. Its early history is the same as that of Aquitania (q.v.). Poitou became a possession of the English crown when Eleanor, Countess of Poitou and Duchess of Aquitaine, married (1152) Henry of Anjou (see HENRY II.). Philip Augustus reconquered it in 1205. In 1360 it reverted to England, but nine years later was retaken by Charles V. See Auber, *Histoire de Poitou* (1886–88).

Poke (*Phytolacca decandra*), an American branching herb, with racemes of white flowers and deep-purple berries (Inkberries or Pigeonberries). See also HELLEBORE.

Poker, a round game at cards (developed from the older game of brag). Each player has five cards dealt him. A sum called the *ante* is deposited by the oldest hand. The players then look at their hands, each in order after the ante saying whether he will play or pass. If he passes he throws down his cards and stakes nothing. If he plays he has to *chip to fill*—i.e. to stake a sum equal to twice the ante; the amount chipped by the ante, if he plays, or *makes good the ante*, is only equal to his first stake. Each player in rotation may then discard any of his cards and receive from the dealer an equal number of cards from the top of the pack, but no one is obliged to discard any. When all have filled, each player in order must either raise his stake or go out of the game, forfeiting what he has already staked. The *raise* is generally limited, but any less sum than the limit may be staked. Subsequent players must either *see* the raise—i.e. make the sum next staked equal to that of the last raiser—or *go better*—i.e. raise higher, or go out of the game. The raising, seeing, going better, or going out, as the case may be, continues until either all the players but one have gone out (when the one left in takes the pool), or until all the stakes of all the players left in are equal, no one going better. Then a *call* is declared. The player to the left of the one who compelled a call has then to show, face upwards, the best combination he holds which has a poker value. The subsequent players in order either show anything they have better, or throw down their hands. The best poker hand takes the pool. In case of absolute equality the pool is divided. The value of the hands is as follows, beginning with the best: (1) *Straight flush*, sequence of five cards of the same suit; (2) *Fours*, four cards of the same rank, accompanied by any other card; (3) *Full*, three cards of the same rank, and a pair; (4) *Flush*, five cards of the same suit, not in sequence; (5) *Straight*, sequence of five cards not all of the same suit; (6) *Triplets*, three cards of the same rank, not accompanied by a pair; (7) *Two pairs;* (8) *One pair;* (9) *Highest card.* The cards rank as at whist (ace highest), except in the case of straights, when ace may be highest or lowest—i.e. ace, king, queen, knave, ten, or five, four, three, two, ace form the highest and lowest straights respectively. If more than one player holds a straight flush the sequence headed by the highest card wins; the same as between two straights. Similarly, the highest fours win, or the highest triplets in triplet hands; in the case of fulls, the holder of the highest triplets wins. As between two flushes, the highest card wins; if these tie, the next highest, and so on. If two players each hold two pairs, the highest pair wins; if the two pairs tie, the remaining highest card wins; with one pair, the same. If none of the players remaining in the game hold any of the above combinations, each shows his highest card; if there is a tie, the next highest, and so on. There are numerous varieties in the way of playing, for which treatises on poker should be consulted. The above describes the simplest form of *Draw Poker*, the game most commonly played. See books by Keller (New York, 1887) and Guerndale (1889).

Poker-drawings, the name given to designs (after well-known pictures generally) burnt into lime-tree or other wood with 'pokers,' which rather resembled plumbers' soldering-irons. The chief 'poker,' 'pyrotechnic,' or 'pyrographic' artists were John Cranch (1751–1823), Smith of Skipton, and Dr Griffiths, the master of University College, for whose chapel he executed an altar-piece after Carlo Dolce. At Knowsley are two poker-drawings ascribed to Salvator Rosa. A similar process, for adorning ships' cabins, table-tops, &c., was patented in 1865.

Pokhurn (*Pokaran*), a town of India, in the Rajput state of Jodhpur, 70 miles NW. of Jodhpur. Pop. 15,000.

Pola, the most important naval station of Austria-Hungary, is situated near the southern extremity of the peninsula of Istria, 105 miles by rail S. of Trieste. The harbour is thoroughly sheltered, deep, and spacious enough to accommodate the largest fleet. The town is protected by forts and batteries, and is overlooked by the citadel, by which it and the bay are commanded. The arsenal employs about 2400 men. There are also artillery and powder stores, docks, slips, &c. The cathedral dates from the 15th century. Pola is also a shipping port, exporting wood, fish, sand, and building stones, and importing provisions, coal, and bricks. Pop. (1851) 1100; (1891) 31,623, of whom 7700 belonged to the garrison. Founded traditionally by the Colchians who were sent in pursuit of Jason, Pola was destroyed by Augustus, but rebuilt at the request of his daughter Julia, on which account it was named *Pictas Julia*. At the beginning of the 3d century it had 30,000 inhabitants, and was a station of the Roman fleet. It was destroyed in 1267 by its Venetian masters, who had conquered it in 1148; and in 1379 the Genoese, after routing the Venetians in a sea-fight off the town, once more ravaged it. But it only passed from Venice in 1797 to Austria, who chose it as her chief naval harbour in 1848. It contains numerous interesting Roman remains, among them a well-preserved amphitheatre, 450 feet long and 360 broad. A temple and several ancient gates are also extant. See Allason's *Antiquities of Pola* (Lond. 1819), and Jackson's *Dalmatia, the Quarnaro, and Istria* (1887).

Polabians, an ancient Slavic race, belonging to the same group as the Poles, occupying the basin of the Lower Elbe. They have long been Germanised, and their language is now extinct. The term is sometimes used in a wider sense for all Slavonic peoples west and north-west of the Oder and the Erzgebirge. See SLAVONIANS.

Polacca, a species of vessel in use in the Mediterranean, with three masts and a jib-boom; the fore- and main-masts being of one piece ('pole-masts'), and the mizzen-mast with a top and topmast.

Polacca. See POLONAISE.

Poland (called by the natives *Polska*, a word of the same root as *Pole*, 'a plain'), a former kingdom of Europe, was, immediately previous to its dismemberment, bounded on the N. by the Baltic Sea from Danzig to Riga, and by the Russian provinces of Riga and Pskov; on the E. by the Russian provinces of Smolensk, Tchernigoff, Poltava, and Kherson; on the S. by Bessarabia, Moldavia, and the Carpathian Mountains; and on the W. by the Prussian provinces of Silesia, Brandenburg, and Pomerania. Its greatest length from north to south was 713 English miles, and from east to west 693 miles, embracing an area of about 282,000 English sq. m. (40,000 larger than Austria-Hungary is now); an area which has a population of over 24,000,000. This extensive tract forms part of the great European central plain, and is crossed by only one range of hills, which rise from the north side of the Carpathians and run north-east through the country, forming the watershed between the rivers which flow into the Baltic and Black Sea. The soil is mostly a light fertile loam, well adapted for cereals, though here and there occur extensive barren tracts of sand, heath, and swamp, especially in the eastern districts. Much of the fertile soil is rich pasture-land, and much is occupied with forests of pine, birch, oak, &c. Rye, wheat, barley, and other cereals, hemp, timber, honey and wax, cattle, sheep, and horses, vast mines of salt, and a little silver, iron, copper, and lead constitute the natural riches of the country; and for the purposes of commerce the Vistula, Dnieper, Dwina, and their tributaries afford great facilities.

The kingdom of Poland, during the period of its greatest extent, after the addition of the grand-duchy of Lithuania at the close of the 14th century, was subdivided, for purposes of government, into about forty palatinates (Pol. *województwa*), which were mostly governed by hereditary chiefs. The people were divided into two great classes—nobles and serfs. The noble class, which was the privileged and governing class, included the higher nobles, the inferior nobles (a numerous class, corresponding to the knights and gentry of other countries), and the clergy, and numbered in all 200,000; the serfs formed the agricultural labourers, and were attached to the soil. Their condition is described by all travellers as a very pitiable one. Such trade as the country had was mostly in the hands of the Germans and Jews. The nobles were the proprietors of the soil, and appropriated the larger portion of its products, the serfs being left with a bare maintenance. The former were brave and hospitable, but quarrelsome, and generally preferred their own interests to that of their country; the serfs (originally called *Kmiecі;* Lat. *Kmetones*) were sunk in poverty and ignorance. The present population of the provinces included in the Poland of former days consists of Poles, Lithuanians, Germans, Jews, Malo-Russians, Roumanians, Gypsies, &c. The Poles, who number 10,000,000, form the bulk of the population; the Lithuanians, 2,100,000 in number, inhabit the north-east of the country; the Germans, of whom there are 2,000,000, live mostly in the towns; the Jews are very numerous, being reckoned at 2,200,000. Of Roman Catholics there are about 9,400,000; of members of the Greek Church (including Uniates), 7,900,000; of Protestants, 2,360,000; the rest are Jews, Armenians in Galicia, &c.

History.—The Poles are ethnologically a branch of the Slavs (q.v.). The name appears first in history as the designation of a tribe, the Poliani, who dwelt between the Oder and the Vistula, surrounded by the kindred tribes of the Masovii, Kujavii, Chrobates, Silesians, Obotrites, and others. In course of time the name Poliani became predominant. There is no real Polish history till the reign of Mieczyslaw (962–992); up to the period of this sovereign we have only fables. He became a convert to Christianity, and Poland took rank as one of the political powers of Europe. Mieczyslaw acknowledged himself to be the feudatory of Otho of Germany. In his time the first Polish bishopric was founded at Posen. He was succeeded by his son Boleslas I. (992–1025), who extended his kingdom beyond the Oder, the Carpathians, and the Dniester. He was recognised as king by the German emperors. After a period of anarchy he was succeeded by his son Casimir (1040–58), whose reign, and that of his warlike son Boleslas II. (1058–1101), although brilliant, were of little real profit to the country. The latter monarch having murdered the Bishop of Cracow with his own hand, Poland was laid under the papal interdict, and the people absolved from their allegiance, whereupon Boleslas fled to Hungary. For two hundred years from this time Poland was only a duchy. Boleslas III., surnamed the 'Wry-mouthed' (1102–39), an energetic monarch, annexed Pomerania.

In the time of Casimir II. (1177–94) we have the senate established, which was formed from the bishops, palatines, and castellans. His death was

the signal for a contest among the various claimants for the throne, which was speedily followed, as usual, by a division of the country, and during this disturbance Pomerania emancipated itself from Polish rule. In 1226 the Teutonic Knights were summoned by the Duke of Masovia to aid him against the pagan Prussians; but they soon became as formidable enemies to Poland as the Prussians, and conquered a large part of Podlachia and Lithuania. The Mongols swept over the country in 1241, committing great devastations, and defeated the Poles in a battle at Liegnitz. Many districts of the country were now colonised by Germans, and numbers of Jews took refuge in Poland. The Germans obtained great privileges from the Polish king, and were governed by the *Jus Magdeburgicum*. The reign of Ladislaus Lokietek ('the Short') is important (1305–33), because in his reign the first Polish diet (1331) was summoned at Checiny. In conjunction with Gedymin, Grand-duke of Lithuania, a vigorous war was carried on against the Teutonic Knights. His son, Casimir the Great (1333–70), increased the prosperity of Poland. Commerce was active, and Danzig and Cracow joined the league of the Hansa. In 1347 was enacted the celebrated Statute of Wislica, the foundation of Polish law; in this reign also Galicia was united to Poland. With Casimir the dynasty of the Piasts became extinct, after a rule of 510 years, according to the old Polish chroniclers. His nephew, Louis, king of Hungary, succeeded him by the will of the deceased monarch and the election of the diet. On his death without male heirs the succession fell to his daughter Jadviga or Hedwig, who was induced by the diet to marry Jagiello, Grand-duke of Lithuania, who founded the dynasty of the Jagellons (q.v.; 1386–1572), and first united Lithuania and Poland, thus doubling the extent, though not the population, of the kingdom. In 1410 the Teutonic Knights were defeated at the battle of Grünwald. His son, Ladislaus, who was also chosen king of Hungary, fell at the battle of Varna in 1444 fighting against the Turks. Casimir, who succeeded, recovered West Prussia from the Teutonic Knights and compelled them to do homage for East Prussia. In 1454 was held the diet of Nieszawa, at which the celebrated statute was enacted which conferred great privileges upon the Polish nobility. The brief reigns of Casimir's two sons were marked only by the increased power of the diet, which had by this time absorbed all but the symbols of supreme authority, and had turned Poland from a monarchy into an oligarchy. The king thus possessed but little power beyond what his personal influence gave him.

Sigismund I. (1506–48), also son of Casimir IV., had a long and prosperous reign, Poland being at that time the dominant country of eastern Europe. Very different opinions have been held about this monarch, some Polish historians praising his government, while Bobrzynski and others consider him to have been a weak man. His court was filled with factions fomented by his wife, Bona Sforza, daughter of the Duke of Milan, a malignant and avaricious woman. The doctrines of the Reformation penetrated to Poland, and were a source of fresh discontents. In a war with Basil, the Grand-duke of Russia, Sigismund lost Smolensk, but he was partly compensated by obtaining lordship over Moldavia. In 1529 Sigismund issued a legal code for Lithuania in the White-Russian language, which forms an important monument of Polish law. In 1537 occurred the first *rokosz*, or rebellion of the nobility against the kingly authority. Sigismund was about to set out to Wallachia, and was obliged to make several concessions before they would accompany him. In 1548 the king died at the advanced age of eighty-two.

He was succeeded by his son, Sigismund II. (1548–72), otherwise called Sigismund Augustus, but this prince was not elected till a debate had taken place about his marriage. He had secretly espoused as a widower a widow of the great house Radziwill, and the nobles required the union to be annulled, because they fancied that the country

would gain more by a foreign alliance. Sigismund, however, carried his point, and his wife was crowned in 1550, but died soon after, not without suspicions of having been poisoned by her mother-in-law, Bona, who in this reign left Poland for her native country, carrying with her a vast amount of treasure. The quarrels between Protestants and Romanists now raged fiercely, and the Reformed faith spread rapidly in Poland. We hear of persons being burned to death for their adhesion to it. Sigismund showed great indecision in the matter. In 1569, by the diet of Lublin, Lithuania was finally joined indissolubly to Poland, and from this time there was to be but one diet for the united realm, and Warsaw, for greater convenience, became the capital. Poland also gained Livonia. In 1572 the king died. In the diet held the year after at Warsaw it was enacted that there should be toleration for all religious opinions, but the nobles were still to have power over their serfs in spiritual matters.

The population almost doubled itself, but the nobles became every year more impatient of restraint, and the crown was now virtually elective. The members of the diet, consisting of the palatines and the *posly*, or deputies of the lesser nobility, together with the higher nobility, sat in one chamber. The king had the right of summoning the diet, which only lasted for six weeks, and its decisions were required at a later stage, as we shall see, to be unanimous. This idea of unanimity in voting is thoroughly Slavonic, and is to be found in the old Russian folk-motes. The right of forbidding the passing of any measure was called in Poland the *liberum veto* (in Polish, *nie pozwalam*), and brought all legislation to a standstill. It was employed by many of the corrupt Polish nobles to avoid the detection of their malpractices or to gratify their private malice, and hastened the ruin of the country.

The diet of 1573 elected Henry of Valois (III. of France, q.v.), a worthless man, who fled in the most ludicrous fashion from the country after a reign of about five months, and was succeeded by Stephen Batory (1575–86), voivode of Transylvania, one of Poland's best kings, who carried on war successfully against the Russians, and compelled Ivan IV. to sue for peace; he also organised the Cossacks of the Ukraine into regiments of frontier soldiers. Batory, who had no heirs, was succeeded by Sigismund III. (1586–1632), the son of Catharine, sister of Sigismund II., who had married John Vasa, king of Sweden. He signed the *pacta conventa*, as the agreement between the Poles and their king was named, and an alliance offensive and defensive was made between Poland and Sweden. Constant disputes took place between the king and the diet, and he was a great persecutor of the Dissidents, as the Protestants were called. Sigismund assisted the claims of the false Demetrius, who was assassinated at Moscow in 1606, and we find the Poles afterwards taking that city and causing Ladislaus, the son of Sigismund, to be crowned czar; but he was soon obliged to resign, and ultimately the family of the Romanovs ascended the throne in the person of Michael. Nor was Sigismund successful in his attempts to get the crown of Sweden. He died in 1632, and was followed by his sons Ladislaus IV. (1632–48) and John Casimir (1648–68). During the reign of this dynasty Wallachia and Moldavia were taken by the Turks from the Polish protectorate, Livonia was conquered (1605–21) by Sweden, and Brandenburg established itself in complete independence (1657). In 1652 Sicinski, the deputy for Upita, first put an end to the diet by the *liberum veto*. The Cossacks had been goaded into rebellion by oppression and religious persecution, as they were members of the Greek Church, and finally went over to Russia in 1654. This occurred in the unfortunate days of John Casimir; and during the same reign Poland was attacked simultaneously by Russia, Sweden, Brandenburg, and the Cossacks; the country was entirely overrun, Warsaw, Wilno, and Lemberg taken, and the king compelled to flee into Silesia. Many of the Polish nobles behaved with great treachery, but the invaders were finally driven out. In 1660 Livonia was ceded to Sweden. In 1667, by the treaty of Andruszowo, the territory beyond the Dnieper was ceded to Russia. John Casimir abdicated in 1668, and retired to France, where he died in 1672.

Michael Wisniowiecki (1668–74), son of a famous general, but a weak and very insignificant man, was elected king—it is said almost against his own will. He was a mere puppet in the hands of his subjects. A war with Turkey was concluded by the ignominious peace of Buczacz in 1672, by which the town of Kamieniec remained in the hands of the Ottomans. But the senate rejected the treaty; the Polish army was reinforced, and the command given to the celebrated John Sobieski, who routed the Turks at Choczim the following year. Michael died suddenly in 1674. After some dissensions concerning the election of a successor, John Sobieski (q.v., 1674–96) was chosen, but his reign, although adorned by the splendid triumph at Vienna (1685), was productive of little good to his country, chiefly through the continual dissensions of the nobles. As Sobieski's successor the Prince of Conti was legally elected and proclaimed king; but Augustus II. of Saxony, whose cause was supported by the House of Austria, entered Poland at the head of a Saxon army, and succeeded in obtaining the throne. Augustus showed little sympathy with his Polish subjects; he promised to reconquer for Poland her lost provinces, but this promise was chiefly made as an excuse for keeping his Saxon army in the country, in violation of the *pacta conventa*. His war with the Turks restored to Poland part of the Ukraine and the fortress of Kamieniec; but that with Charles XII. brought nothing but misfortune. Cracow was taken in 1702; Augustus was deposed, and Stanislaus Leszczynski, palatine of Posen, elected in his place. All the courts of Europe acknowledged Stanislaus, except that of Peter the Great; and, when the latter defeated Charles at the battle of Pultowa in 1709, Leszczynski was compelled to leave the country, and Augustus returned. In this reign Poland lost Courland, one of its fiefs, which was given by the Empress Anna to Biron, her favourite. Religious fanaticism was also rampant. The Dissidents were very much persecuted, and a riot having taken place in 1724 at Thorn, several of the leading citizens, including the burgomaster, were put to death. In 1733 a law was passed excluding them from all public offices. This same year the contemptible Augustus died. At the instigation of some of his supporters, Stanislaus Leszczynski, who was then residing in Lorraine, was induced to return to Poland and was elected king; but his election was opposed by Austria and Russia, and in his place was chosen Augustus III. (son of the last sovereign), a weak and incapable man. The condition of the country was now deplorable. Towards the end of his reign the more enlightened Poles, seeing the radical defects of the constitution, the want of a strong government, and the dangers of the *liberum veto*, entered into a league for the establishment of a well-organised hereditary monarchy. The conservative party, however, was strong, and relied on Russian influence, while the reformers supported the Jesuits in their exclusion of dissenters

from public offices. In 1764 Stanislaus Augustus Poniatowski was elected king, chiefly through the intrigues of the Empress Catharine. Although a man of refined manners, he was weak, and not fitted to serve the country at such a crisis. The reforming, or Czartoryski party (so called because it was headed by a member of this celebrated family), had succeeded in abolishing the *liberum veto*, and effecting many other improvements; but they at the same time more severely oppressed the Dissidents, whom the Russians pretended to protect.

The Confederation of Bar (so called from Bar in Podolia) was now (1768) formed by a few patriots, an army of about 8000 men was assembled, and war declared against Russia. But they were not successful, and a bold attempt to carry off the king also failed. Frederick the Great of Prussia, who had formerly gained the consent of Austria to a partition of Poland, made the same proposal to Russia in 1770, and in 1772 the *first partition* was effected. The territories seized by the three powers were as follows:

	English sq. miles.	Population.
Russia	42,000	1,800,000
Prussia	13,000	416,000
Austria	27,000	2,700,000

The whole country was now aroused to a sense of its danger; and the diet of the diminished kingdom laboured to amend the constitution. In 1788 a remarkable diet was opened which lasted four years. Many changes were introduced. The *liberum veto* was formally suppressed, and the throne was declared hereditary. The burghers were to send deputies to the diet on the same terms as the nobles; the peasants were not set free, but their condition was improved; and the Dissidents were granted complete toleration, although the Roman Catholic was declared to be the dominant religion. In this they were encouraged by Prussia, whose king, Frederick-William, swore to defend them against Russia. The new constitution was promulgated May 2, 1791. But some of the nobles were discontented at the loss of their privileges by the new order of things, and formed in 1792 the Confederation of Targovica (q.v.), and at their instigation Russian troops invaded Poland and Lithuania. Prussia now joined the Russians, and a second fruitless resistance to the united troops of Prussia and Russia, which was headed by Joseph Poniatowski (q.v.) and Kosciusko (q.v.), was followed by a *second partition* (1793) between those two countries as follows:

	English sq. miles.	Population.
Russia	96,000	3,000,000
Prussia	22,000	1,100,000

which the diet was forced to sanction at the point of the bayonet. The Poles now became desperate; a general rising took place (1794), the Prussians were compelled to retreat to their own country, and the Russians were several times routed. But Austria now appeared on the scene; her army advanced, and fresh Russian troops also arrived. Kosciusko was defeated at the battle of Maciejowice and taken prisoner. Suvorov (Suwarrow), the Russian general, took Warsaw, and the Polish monarchy was at an end. The *third and last partition* (1795) distributed the remainder of the country as follows:

	English sq. miles.	Population.
Russia	43,000	1,200,000
Prussia	21,000	1,000,000
Austria	18,000	1,000,000

King Stanislaus resigned his crown, and died at St Petersburg in 1798. He lies buried in the Roman Catholic church there.

The main causes of the fall of Poland appear to have been (1) the want of patriotism and cohesion among the nobles, each pursuing his own interests, and the country thus being divided among a number of petty tyrants; (2) the want of a *national* middle class, the trade of the country being almost entirely in the hands of Jews and Germans; (3) the intolerance of the Jesuits, who persecuted on the one hand the Dissidents, which caused them to sympathise with Prussia, and on the other persecuted also the Orthodox inhabitants of the eastern provinces and the Cossacks, who thus looked to Russia; (4) in a less degree than the first three causes, the weakness of character of the kings—though with such a turbulent nobility it must be confessed that they had no fair play; (5) the want of natural frontiers.

The subsequent success of the French against the Russians and the promises of Napoleon to reconstitute Poland rallied round him the Poles, who distinguished themselves in several campaigns against their old enemies; but all that Napoleon accomplished in fulfilment of his promise was the establishment, by the treaty of Tilsit (1807), of the duchy of Warsaw, chiefly out of the Prussian share of Poland, with a liberal constitution and the Elector of Saxony as its head. In 1809 Western Galicia was taken from Austria and added to the duchy, but the advance of the allied army in 1813 put an end to its existence. After the cessions by Austria in 1809 the duchy contained 58,290 English sq. m., with a population of about 4,000,000. Danzig was also declared a republic, but given back to Prussia (February 3, 1814).

The division of Poland was rearranged by the Congress of Vienna in 1815; the original shares of Prussia and Austria were diminished, and that part of the duchy of Warsaw which was not restored to Prussia and Austria was united as the kingdom of Poland to the Russian empire, but merely by the bond of a personal union (the same monarch being the sovereign of each), and the two states being wholly independent of each other. The remaining parts of Poland were incorporated with the kingdoms which had seized them. The partition of Poland as thus finally arranged was as follows:

	Eng. sq. m.	Pop.	Present Political Divisions.
Russia	220,500	16,000,000	Provinces of Courland, Vitebsk, Grodno, Minsk, Mohileff, Volhynia, Kieff, Podolia, and the Kingdom of Poland (see below). Of these portions of the original kingdom of Poland now belonging to Russia it must be remarked that Courland was ceded to Russia in the reign of Catharine by the free action of the inhabitants; Kieff had belonged to Russia by conquest since 1667.
Prussia	26,000	3,000,000	Posen, most of West Prussia, and several districts of East Prussia.
Austria	35,500	5,000,000	Galicia, Bukowina, Zips, &c.

Cracow, with a small surrounding territory, was declared independent under the protection of Austria. Alexander I. gave the Poles a constitution, including biennial diets, a responsible ministry, a separate army, and liberty of the press. General Zajacek was appointed viceroy, and the Grand-duke Constantine took command of the army. For some time matters seemed to go on smoothly, but a spirit of discontent soon developed itself. Complaints were made that the freedom of the press was interfered with, and secret societies were formed. An insurrection broke out in November 1830; the grand-duke was obliged to quit the city, and General Chlopicki was appointed dictator. Early in 1831 a large Russian army, under Diebitsch, entered the country. Chlopicki

resigned his dictatorship, and Prince Czartoryski was appointed president of the provisional government. From January 1831 till 8th September of the same year a series of sanguinary engagements took place, in which the Poles were at first successful. On the 8th of September, however, Paskevitch (q.v.), who had succeeded Diebitsch, took Warsaw, and the insurrection was virtually at an end. The Poles had not succeeded in obtaining any assistance from foreign powers. From this time the independence of Poland was suppressed, and in 1832 it was declared an integral part of the Russian empire, with a separate administration, headed by a viceroy chosen by the czar; the constitution was annulled, and a strict censorship of the press was established. Many of the literary treasures were carried off to the public library of St Petersburg. Slight outbreaks occurred in 1846, which were severely repressed. Simultaneous disturbances in the Prussian and Austrian portions of Poland met with the same fate. Their leaders in Prussia were imprisoned, but released by the revolution of 1848 at Berlin. In no part of the lost provinces has the work of denationalisation been more complete than in Prussian Poland. It has proceeded quietly, but thoroughly. In Galicia the peasants at the same time massacred many of the nobles. On the 6th of November 1848 the republic of Cracow was incorporated with Austria.

After the accession of Alexander II. in 1855 the condition of the Poles was considerably ameliorated. An amnesty brought back many of those who had been expatriated, and various other reforms were hoped for. On the 29th November, on the thirtieth anniversary of the insurrection, many political manifestations took place, both in the churches and elsewhere. On these occasions riots took place, and some persons were unfortunately killed. Warsaw was now declared in a state of siege. In June 1862 an attempt was made to assassinate General Luders, the governor, who was succeeded by the Grand-duke Constantine, the brother of the emperor, the Marquis Wielopolski being appointed chief minister. Meanwhile Alexander II. had made great concessions; the public offices of the country were to be filled by Poles; the Polish language was to be the official one, and municipal institutions were granted to Warsaw and the chief cities. The people, however, received these overtures sullenly, and on the night of January 15, 1863, a secret conscription was held, and those suspected of disaffection to the government were seized in their beds to be enlisted. Attempts were made to assassinate the grand-duke and other Russian officials, and Lithuania and Volhynia were also declared in a state of siege. The committee of the National government issued its first proclamation in February 1863; and a week afterwards Mieroslawski raised the standard of insurrection in the north-east, on the frontier of Posen. The committee (*Rzad*) had secret sessions, and was for a long time able to defy the Russian government: its emissaries, called *stilctcziki*, put to death many obnoxious persons and Russian spies. It also issued proclamations from time to time; and many districts of Augustovo, Radom, Lublin, Volhynia, and Lithuania were speedily in insurrection. It was a mere guerilla war, and no great or decisive conflicts took place; but the sympathy of Europe was largely enlisted on behalf of the Poles. Incendiarism and murder were rampant; and at last, with the assistance of Prussia and the secret support of Austria, the czar's troops succeeded in trampling out (1864) the last embers of insurrection. Langiewicz, one of the leaders who had directed the struggle, held out for some time, but at length made his escape into Galicia. From the time of the suppression of the insurrection the kingdom of Poland has disappeared from all official documents. All education in the university and the schools is now carried on in the Russian language.

Among histories may be recommended *Histoire de Pologne*, by Lelewel (Paris, 1844); *Geschichte Polens*, by Röpell and Caro (vols. i.–vi., Gotha, 1840–88); *Dzieje Polskie w Zaryzsie* ('Sketch of the History of Poland'), by Bobrzynski. See also Count Moltke's *Poland* (Eng. trans. 1885), and the present writer's *Poland* (1893). For maps of Poland at various dates, see, besides that given above, the historical maps of Europe, Vol. IV. p. 466.

Russian Poland.—The so-called 'Kingdom of Poland,' united to Russia in 1815, had its own constitution till 1830, and a separate government till 1864, when, after the suppression of the revolt, the last visible remnant of independence was taken away. The administration was at first given to eight military governors, and then to a commission sitting in St Petersburg. Finally, in 1868, the Polish province was absolutely incorporated with Russia, and the ten governments into which it was divided are grouped with the governments of Russia proper. In 1867 the area of the 'kingdom' was about 49,000 sq. m., with a population of about 5,700,000, of whom 4,330,000 were Roman Catholics, 780,000 Jews, 260,000 Greek Catholics (mostly United), and the rest Lutherans or other Protestants. In 1890 the ten Polish provinces—Kaliscz, Kielce, Lomza, Lublin, Piotrkow, Plock, Radom, Siedlce, Ssuwalki, and Warsaw—had a collective population of 8,105,000. The several areas and populations of these governments will be found in the table at Russia. About 10,000,000 still here and in Prussia and Austria speak the Polish tongue. The surface and soil of the Russian Polish provinces resembles that of the rest of old Poland; the commerce is still mostly in the hands of the Jews.

Polish Language and Literature.—The Polish language is one of the most widely-spread branches of the Slavonic family; it forms the western branch together with Bohemian and Sorbish or Lusatian Wendish. Like all the Slavonic languages, it is highly inflected, having seven cases, and, by means of the so-called 'aspects,' expressing very delicate distinctions of meaning in the verb. Like Russian, however, it lacks the imperfect and aorist which are found in Bulgarian and Serbian. It has a rich vocabulary and great power of compounding words. It resembles the Old Slavonic in having two nasals, like the French *on* and *in*; these are found nowhere else among Slavs except in a Bulgarian dialect. After the introduction of Christianity Latin exercised a great influence on its vocabulary and literature, and subsequent to the 14th century it adopted into its vocabulary numerous German words. Already in the 16th century Polish was a highly cultivated language, and began to supplant Latin, until then the language of the state and of the learned. The best Polish grammars are those of Malecki, *Gramatyka Historyczno-Porównawcza Jczyka Polskiego* ('Historico-comparative Grammar of the Polish Language,' Lemberg, 1879), and C. W. Smith, *Grammatik der polnischen Sprache* (Berlin, 1845); the most comprehensive dictionary is that of Linde (new ed. Lemberg, 1854–60); that of Bandtke (2 vols. Breslau, 1806) is good, and so also is the English-Polish dictionary published at Berlin in 1849.

The history of Polish literature is divisible into five distinct periods. (1) From the earliest times to the middle of the 16th century, the epoch of the Reformation. The Poles, unlike most of their Slavonic kindred, are poor in legendary and popular poetry, and much of their early literature is in Latin. Casimir III. (q.v.), surnamed 'the Great,' did more than any other early Polish

monarch for the encouragement of literature, and among other things founded the university of Cracow, which has continued to be the centre of intellectual life and culture in Poland. Among the very oldest literary monuments is a hymn to the Virgin Mary, ascribed to St Adalbert. The MS. in which it is preserved is dated 1408. Belonging to the middle of the 14th century is the so-called psalter of Queen Margaret, discovered at the convent of St Florian in 1826, which has been edited by Professor Nehring; there is also the Bible of Queen Sophia, which has come down in an imperfect copy, and is said to have been written about 1455; it has been edited by Professor Malecki. Writers of Latin chronicles were Martin Gallus, who flourished between 1110 and 1135, Kadlubek (1160–1223), and Jan Dlugosz or Longinus (1415–80), all of whom were ecclesiastics. The last is also worthy of remembrance as an able diplomatist. Jan Laski, Archbishop of Gnesen (1457–1531), published a valuable collection of the oldest Polish laws, *Commune Inclyti Poloniæ Regni Privilegium*. In 1474 the first printing-press was established at Cracow by Günther Zainer; the first book in the Polish language was published there in 1521. In 1543 died the great astronomer Nicholas Copernicus. Some other specimens of Old Polish before the 16th century will be found collected in the valuable work of Nehring, *Altpolnische Sprachdenkmäler* (Berlin, 1887).

(2) The second period of Polish literature embraces that which is called the golden age (1548–1606). The series of poets begins with Nicholas Rej (1505–69), commonly called the 'father of Polish poetry,' who spent his life at the courts of the Sigismunds. He was a Protestant. His best work is *Zwierciadlo albo zywot Poczciwego Czlowieka* ('The Mirror: or the Life of an Honourable Man,' 1567); he also wrote a play on the subject of Joseph. Although his language is rough and careless, there is much shrewdness and satire in his writings. Jan Kochanowski (1530–84), called the prince of Polish poets, has left a great deal of verse, the most beautiful of which are his *Treny* or Lamentations on the death of his daughter Ursula. His nephew Peter translated the *Jerusalem Delivered* of Tasso. Szarzynski (died 1581) introduced the sonnet into Polish. Szymonowicz (1557–1629) was a writer of good pastorals (*Sielanki*), as was also Zimorowicz (died 1629), a native of Lemberg. Sebastian Klonowicz, called Acernus (died 1602), is celebrated as a satirist and descriptive poet. The Reformation made rapid progress in Poland; many of the nobility were Calvinists, and the Socini came to reside in the country. Translations of the Bible appeared, but the Jesuit reaction soon made itself felt, especially under the influence of Skarga (1552–1612), renowned for his pulpit eloquence. Among the historians of this period the most celebrated are Martin Bielski, whose Chronicle was continued by his son Joachim; Lukas Górnicki (died 1591), author of a history of the Polish crown (*Dzieje w Koronie Polskiéj*, Crac. 1637); Stryikowski (died 1582), whose Chronicle of Lithuania (Königsb. 1582) is an admirable work; and Paprocki (died 1614).

(3) The third period of Polish literature, also called the Macaronic (1606–1764), is coincident with the rule of the Jesuits, who first obtained a footing in Poland about 1566, through the influence of Cardinal Hosius, soon got possession of the schools, and seriously checked the intellectual development of the nation. The literature of the period is for the most part poor, consisting mainly of bombastic panegyric; the language being corrupted by Latinisms and frequently by the introduction of whole Latin sentences—hence the term Macaronic. To this period belong Casimir Sarbiewski, known by his Latin name Sarbievius (1595–1640), a celebrated writer of Latin odes; Waclaw Potocki, now known to have been the author of the poem *Wojna Chocimska*, or War of Chocim, long preserved in manuscript; Kochowski (died 1699), a soldier-poet, who has left some sprightly odes; Twardowski (died 1660), a very prolific writer, author of a poem on Ladislaus IV.; Opalinski (1609–1656), who has left some bitter satires reviling his countrymen, whom he betrayed to the Swedes; Chroscinski, the translator of Lucan; Morsztyn, the translator of Corneille; and Elizabeth Druzbacka (died 1760), whose writings show some feeling for nature. History again took a Latin form, in spite of its having been written in the golden age in Polish: we may mention Starowolski (died 1656), author of *Polonia, sive Status Regni Poloniæ Descriptio* (Wölfenbuttel, 1656), and other works; Kojalowicz, a Jesuit (died 1677), who wrote a History of Lithuania; and Kaspar Niesiecki, a Jesuit (died 1744), whose *Korona Polska* (4 vols. Lemb. 1728–43) is the most important work on Polish heraldry.

(4) The fourth period is that of the reign of Stanislaus Poniatowski and the dismemberment of Poland, till the rise of romanticism (1764–1822); it owes its characteristics partly to the influence of French culture, partly also to the patronage of literature and science by King Stanislaus, the princes Czartoryski, Jablonowsk, and other noblemen, and the educational reforms of Stanislaus Konarski (1700–73). The good work begun by Konarski was carried on by Kopczynski (1735–1817), who was the first to establish on a scientific basis the grammar of the Polish language in his *Grammatyka Narodowa;* other authors were Bohomolec and Zablocki, who adapted a great many French pieces for the stage. But the best writer for the stage was Fredro, who belongs to a later period. The most noted dramatist, however, of this time, who may perhaps be called the real founder of the Polish stage, was Boguslawski (1759–1829), who wrote above eighty plays, the majority of which, under the title of *Dzieła Dramatyczne*, were published at Warsaw (9 vols. 1820). The most conspicuous poet of this time was Ignacy Krasicki (1735–1801), who tried all kinds of literature—an epic on the war of Chocim, a weak production, and some satires and fables. We must also mention Trembecki; Cajetan Wegierski, the satirist; Godebski, and Wezyk. Adam Naruszewicz was but a mediocre poet, but he wrote a valuable *Historya Narodu Polskiego* ('History of the Polish People'), which he carried down to the year 1386. In 1801 the historian Tadeusz Czacki, Franciszek Dmochowski, and Bishop Jan Albertrandy founded at Warsaw the 'Society of the Friends of Knowledge,' which especially under the auspices of Staszyc bore good fruit till it was dissolved in 1832, when its library of 50,000 volumes was carried off to St Petersburg. At the same time Jozef Ossolinski, Hugo Kollataj, and Stanislaus Potocki by word and writing exercised a great influence on the renovation of the national spirit. Karpinski (1745–1825) was a very popular poet as a writer of sentimental elegies and idylls, and Woronicz (1757–1829) was celebrated both as a poet and divine. Niemcewicz (1757–1841) was a statesman and soldier, and is remembered for his historical songs (*Spiewy Historyczne*). Lastly, as the great precursor of the romantic school, must be mentioned Kasimir Brodzinski (1791–1835), whose idyll *Wieslaw* has been much admired.

(5) The fifth period comprises from 1822 to the present time; the era of romanticism, dating from the appearance of Mickiewicz, the greatest Polish poet. At Wilno, which after 1815 became the centre

of Polish literary activity, several young men united, with Adam Mickiewicz (1798–1855) at their head, in a crusade against the still dominant French school of literature. After a short stay in Russia, Mickiewicz emigrated and spent the latter part of his life at Paris. He died at Constantinople, whither he had gone on a political mission at the time of the Crimean war. We have only space to mention some of his chief works, his *Ballads, Sonnets, Konrad Wallenrod,* and *Pan Tadeusz;* the last probably the most popular poem in the Polish language. Anton Malczewski (1792–1826), remembered by his *Maria,* a pathetic story of the Ukraine, was a prominent poet of what has been called the Ukraine school; Goszczynski (1806–76) was author of the narrative poem *Zamek Kaniowski;* Bohdan Zaleski, author of *Duch od Stepu;* others are Odyniec, the friend of Mickiewicz, Siemienski, Garczynski, Gaszynski. The two names most worthy to be placed by the side of that of Mickiewicz are those of Sigismund Krasinski (1812–59), author of the strange poem *Nieboska Komedya* (the 'Undivine Comedy'), and Julius Slowacki (1809–49). Most of these men belonged to what was called the 'Polish Emigration,' whose headquarters were at Paris. Of the Polish novelists we have only space to mention the prolific Jozef Ignacy Kraszewski (1812–87), whose works amount to 312, and Henry Sienkewicz. The most original writer for the stage whom the Poles have produced is Count Alexander Fredro (1793–1876); he is a thoroughly national writer; although French influence is visible in his pieces, the characters are Polish. Many distinguished historical writers belong to this later period, of whom we may mention Joachim Lelewel (1786–1862), the author of many works of the greatest value, Szujski, Schmitt, Szajnocha, and Michael Bobrzynski, professor in the university of Cracow. By these men the history of Poland has been treated in all its details with great vigour. Among later poets may be mentioned Pol, Ujejski, and Lenartowicz; Adam Asnyk, the most popular of recent Polish poets; and the poetesses Gabriele Zmichowska (1825–78) and Marya Konopnicka.

The history of Polish literature has been written by Bentkowski and Wiszniewski. Mention may also be made of Nitschmann's *Geschichte der Polnischen Literatur* (1884), and the present writer's *Early Slavonic Literature* (1883) and *Poland* (1893).

Polar Bear. See BEAR.

Polar Circle. See ARCTIC.

Polar Exploration. In scientific geography much of the best work done in the 19th century is due to discoveries made in the Arctic and Antarctic regions. In the former, more especially, not only have new lands been surveyed, but large and important accessions have been made to several branches of natural science. The original motive, however, in England at least, for exploring the Arctic seacoasts was to discover a route to the wealthy countries of eastern Asia, and to share in the traffic monopolised by Spain and Portugal when at the height of their power. Thus arose a double series of attempts, either to coast eastward along the north of Enrope and Asia, or to sail westward across the Atlantic; the latter being afterwards modified into attempts to coast westward along the north of America. Hence arose the terms 'North-east Passage' and 'North-west Passage.'

Some have traced the history of Arctic exploration to the time of King Alfred, who, in his translation of Orosius (q.v.), inserted an account of the voyages of Othhere and Wulfstan, narrated to him by Othhere himself, who seems to have sailed round the North Cape to Lapland. The voyages of the Norsemen to Greenland (q.v.) and the opposite coasts of America in the 10th and following centuries may be regarded as to some extent coming within early Arctic attempts. Cabot's discovery in 1497 of Newfoundland and Labrador might, however, be termed the first step in the exploration of American polar regions—for the earlier expeditions claimed on behalf of Portugal must be regarded as mythical. Three years after Cabot, Gaspar Cortereal and his brother made three separate voyages in the same direction, sailing northwards by Labrador, where they were stopped in 60° N. lat. The expedition commanded in 1553 by Sir Hugh Willoughby led the way to the North-east Passage. Willoughby sighted Nova Zembla, but he and his men ultimately perished on the coast of Lapland. Chancellor, who accompanied him, landed in Russia near Archangel. Other Englishmen followed, Burroughs (1556), Pet and Jackman (1580), Henry Hudson (1608–9), Wood (1676), but none succeeded in getting much beyond Nova Zembla, though they did good work in exploring the north coast of Europe, Spitzbergen, and other islands in these seas. In 1594–97 Barentz, a Dutchman, led three expeditions, wintering on the north-east coast of Nova Zembla, 1596–97 (see BARENTZ). After the failures of Hudson and Wood in the 17th century, the attempt to sail eastwards came to be considered quite hopeless. In 1607 Hudson succeeded in reaching 81° 30′ N. in the neighbourhood of Spitzbergen.

Meanwhile some exploration of the Arctic parts of America had been going on. Frobisher first sailed in 1576, and in 1585–88 the great navigator Davis sailed up the strait bearing his name to 72° 41′ N. and coasted the west of Greenland, 'the land of desolation.' In a tract of Davis', published in 1595, there are arguments for a North-west Passage. Hudson, who had tried the North-east Passage, discovered in 1610 the strait and great bay which bear his name. From the size of the latter he concluded it to be part of the Pacific; but that was disproved by Button, the next English explorer (1612). In 1615–16 Baffin, who went out at first under Bylot, had had some scientific training, proved himself as skilful a navigator as Davis. He found the great northern outlet to Baffin Bay, and recorded some important magnetic observations. After the expedition of Fox and James in 1631, which only led to the partial exploration of what then was named Fox Channel, the North American coast was neglected for more than a century.

Russia was naturally interested in the exploration of the Siberian coast, and from Peter the Great's time took her proper share in the maritime discovery. Behring, after receiving instructions from Czar Peter on his death-bed, sailed from Okhotsk, and discovered the straits which bear his name. In a second voyage (1741) he sailed from Petropaulovski and explored part of north-west America. Another Russian expedition in 1742 found (but did not succeed in rounding) the most northerly point of Siberia, named from the discoverer Chelyuskin (or Severo); and an earlier one sailed from the Yenisei to 75° 15′ N. In 1765 Tchitsakoff sailed to Spitzbergen, and finally reached 80½° N. The New Siberian Islands were explored by Hedenström in 1809–11, by Anjou in 1823, and in 1884–87 by Bunge and Toll. Wrangel explored the Siberian coast between Cape Chelagskoi and the Kolyma in 1820–23, and in 1843 Middendorf laid down the unvisited coast in the neighbourhood of Cape Chelyuskin. In the reign of George III. there was a new revival of English zeal in naval adventure. Captain Phipps (afterwards Lord Mulgrave) sailed in June 1773 to Spitzbergen, where the heavy pack-ice kept him nearly a month from proceeding farther north. Finally he reached 80° 48′ N., and Cook, who next made the attempt,

could only penetrate to 70° 45′. The government offered a prize of £5000 to any crew that should reach 89° N. long.; but after those failures there was no effort made till 1806, when Scoresby reached 81½° N. immediately above Spitzbergen. In following expeditions Scoresby explored Jan Mayen Island and the east coast of Greenland, largely adding to our knowledge of the physical geography and natural history of the Arctic regions. The expeditions of Buchan and Franklin in 1818, of Clavering in 1823, of Graah in 1828, of De Blosseville in 1833, did not reach higher latitudes than those which preceded them.

To encourage polar exploration on the North American coast the British government had promised a reward of £20,000; yet nothing was done till the Admiralty in 1818 sent out Ross and Parry, who only explored part of Lancaster Sound. Next year Parry alone discovered Prince Regent Inlet, Barrow Strait, and (110° W.) Melville Sound. Following up this line of exploration, Ross in 1829 at last reached a point only 200 miles from Turnagain

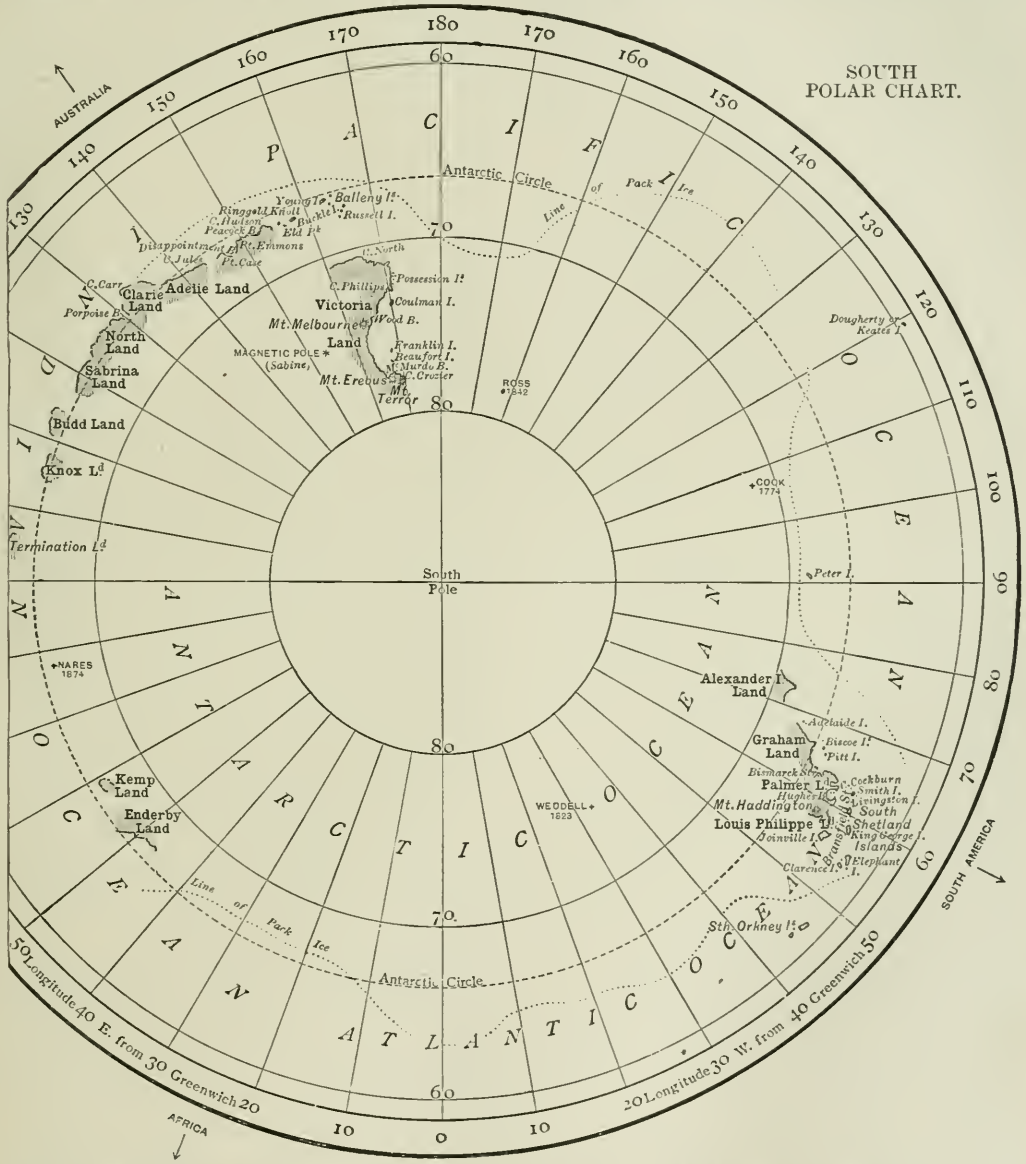
number of search-parties which it occasioned. His object was to penetrate to Behring Strait from Lancaster Sound (see FRANKLIN, SIR JOHN). In 70° N. lat., 98° 30′ W. long., on the west side of King William's Land, the ships were beset, and Franklin died June 1847. The survivors abandoned the ships, and all perished. Many search-expeditions were sent out. One of these, under Collinson and M'Clure, sailed from Plymouth to Behring Strait in 1850. Fixed in the ice on its eastward voyage, M'Clure's ship was rescued next spring by Sir Edward Belcher, about 60 miles west of Barrow Strait. Belcher now returned towards the Atlantic, and thus M'Clure with his crew reached England in 1854 after actually traversing the North-west Passage from ocean to ocean. He therefore received the honour of knighthood, and a sum of £10,000 was voted by parliament to him and the crew. One of the last search-expeditions was that in the *Fox*, under Captain (now Sir) Leopold M'Clintock, sent out by Lady Franklin in 1857. M'Clintock obtained many relics from the



Eskimo of Boothia, and in a cairn in Point Victory found the record which told the story of the expedition. Perhaps we should here note the fact that afterwards, 1879–80, one of the United States search-expeditions, under Lieutenant Schwatka, found evidence that Franklin had really completed the discovery of the North-west Passage. Owing to the different Franklin expeditions from Great Britain and the United States the whole Arctic coast of North America was explored almost exhaustively, so that several routes are now completely mapped between Davis Strait and Behring Strait. For commercial purposes, however, the North-west Passage is of no value whatever.

And now to return to the North-east Passage. In 1827 Parry sailed to Spitzbergen, and after much toilsome effort reached 82° 40′ N. After that little was done in this region till Sweden began to take an active interest in the exploration, under the active guidance of Professor (afterwards Baron)

Nordenskiöld, who in 1858–72 did much exploring work in the Spitzbergen islands and seas. In two voyages he reached the Gulf of Obi. At last, in 1878, he rounded Cape Chelyuskin, 77° 41′ N., and after wintering near Behring Strait sailed into the Pacific and reached Yokohama, 2d September 1879. Thus, three and a quarter centuries after the attempt of Willoughby, the North-east Passage was at last completed. Before that date an Austrian expedition under Lieutenants Payer and Weyprecht had been singularly successful, having discovered an island about 200 miles north of Nova Zembla, as large apparently as Spitzbergen. This new country, Franz-Josef Land, extends from 80° N. to about 83°. At a later date (1880) this land was still farther explored to the north-west by Mr Leigh Smith; and in the winter of 1881–82 Mr Leigh Smith wintered at Franz-Josef Land, he and his companions having great difficulty in escaping.

The more recent exploration to the north of America has added little to our geographical knowledge, however interesting in certain scientific aspects. The expedition of Kane and Hayes in 1853–55 reached in sledges Cape Constitution in 82° 27′ N., and saw what appeared to be an open polar sea. Hayes again (1860–61) reached 81° 35′ N. In 1871 the *Polaris*, under Captain C. F. Hall, sailed from New London, U.S., and reached the latitude 82° 16′, which was surpassed in 1876 by the English expedition under Captain Nares; Captain A. H. Markham, by means of sledges, reaching 83° 20′ N. At the same time Aldrich explored the north shore of Grinnell Land. More famous and more disastrous was the 'Lady Franklin Bay Expedition,' 1881–84, conducted by Lieutenant Greely; the relief party sent in the summer of 1883, being unfortunately entrusted to military men, failed to reach the explorers, who were, therefore, compelled to abandon their ships and find their way southwards through almost impassable ice. In October 1883 Greely and his brave companions landed at Cape Sabine, the bleakest spot probably in all the Arctic regions; and there in June 1884 Commander Schley found the six men who still survived. Greely and his assistants took scientific observations up to the day of their release. In the early part of Greely's exploration, when in Grinnell Land, one of his party, Lieutenant Lockwood, succeeded in reaching 83° 23·8′ N. lat., on the coast of Greenland, which is a few miles nearer the pole than the point reached by Markham. The Greely expedition also explored the interior and the west coast of Grinnell Land. In 1869–70 Captain Koldewey's expedition reached 77° N. on the east coast of Greenland, the highest latitude yet attained on that coast. The *Jeannette* expedition under Commander De Long, sent out by the *New York Herald* in 1879 to push north by Behring Strait, ended in disaster. The vessel was crushed in the ice in June 1882 in 77° N., 155° E., and De Long and many of his men perished. Lieutenant Berry, sent out to search for the *Jeannette*, explored Wrangel Land. The icy plateau which covers Greenland (q.v.) was in 1888 crossed by Nansen, and Peary did good work there in 1886–1900. In 1893–96 Nansen (q.v.) reached 84° 4′ in the frozen-in *Fram*, and 86° 14′ on the ice afoot. Andree started on his still more adventurous ballooning expedition to the Pole in July 1897; and in 1899–1900 a party under the Duke of Abruzzi reached lat. 86° 19′ 48″.

At the suggestion of Lieutenant Weyprecht, an international series of polar observatories was established around the north polar area, for the purpose of taking a complete year's observations, beginning with August 1882. The stations selected were the following: Bossekop, in Lapland (Norwegians); Ice Fjörd, Spitzbergen (Swedes); Lena Mouth, Siberia, and Möller Bay, Nova Zembla (Russians); Dickson Harbour, mouth of the Yenisei (Dutch, but the expedition failed to reach its destination); Great Slave Lake (English); Point Barrow on north coast of America, east of Behring Strait, and Lady Franklin Bay, in Grinnell Land (the United States, the latter being Greely's expedition); Cumberland Bay, Davis Strait (Germans); Jan Mayen Island (Austrians); Godthaab, Greenland (Danes). The Germans had also a station on South Georgia Island, on the verge of the Antarctic, and the French on the south coast of Patagonia. The result was a series of observations of high value on the physics, meteorology, and natural history of the polar, especially the Arctic regions. The Russian expedition at the mouth of the Lena was continued for some years under Bunge and Toll, who not only explored the mainland, but made a thorough investigation of the New Siberian Islands.

It only now remains to survey shortly the polar explorations of the mighty Southern or Antarctic Ocean. Some of the earlier navigators of the 16th and 17th century were drifted south as far as South Georgia and South Shetland. Cook was the first to undertake a systematic exploration of the region, sailing all round at a high latitude, and so disproving the existence of the 'Great Southern Continent' to be found on old maps. Cook reached 71° 15′ S., in 106° 50′ W. In 1821 the Russian Bellinghausen discovered the islands named Alexander Land and Peter Land. Weddell afterwards sailed south to 74° 15′, and in 1831 Biscoe discovered Enderby Land, 65° 57′ S., and Graham Land, 67° S. The French expedition, 1838, under D'Urville, found its advance to the pole blocked by a bank extending east and west for 300 miles; La Terre Adèle, in 140° E., was first named in this voyage. In 1840 the United States expedition under Captain Wilkes discovered a long coast-line, apparently extending from Enderby Land eastwards to Ringold's Knoll, but the only part of this which has since been found was discovered by Balleny in 1839. The most important results obtained in the Antarctic region are due to Sir James Clarke Ross, who made three voyages in 1839–43, discovering Victoria Land, with a lofty range containing the volcanoes Erebus and Terror. He traced the coast from 71° S. to 78° 10′, the highest latitude yet reached in the Antarctic, after passing some ice-floes which were 1000 miles broad. These southern expeditions of Ross, like those of all the chief polar explorers, have supplied valuable information for students of magnetism, meteorology, geology, and natural history, besides extending the bounds of geographical science. The *Challenger* expedition only just crossed the Antarctic circle.

The general result of all the exploring work is that in the north polar regions the unknown has been pushed back to within 80° N. lat.; while in the Greenland and the Nova Zembla regions exploration has been carried to within about 400 miles from the North Pole. On the other side, with the exception of patches here and there, the south polar region is a great blank within the Antarctic Circle. The German government subsidised a scientific expedition to the Antarctic to start in 1901; a national British expedition, organised by the Royal Geographical Society, with funds provided partly by subscription and partly from government, co-operates with it, each exploring a separate part of the ocean.

The physical geography of the north and south polar regions is largely treated at ARCTIC OCEAN, ANTARCTIC OCEAN. See also GEOGRAPHY, GEOGRAPHICAL DISTRIBUTION, GREENLAND, SPITZBERGEN, NOVA ZEMBLA, FRANZ-JOSEF LAND, SIBERIA, NEW SIBERIAN ISLANDS, OB, GLACIER, ICE, and the articles on Hudson, Cook,

Franklin, Ross, Parry, M'Clure, M'Clintock, Hall, Nordenskiöld, Greely, and other Arctic and Antarctic explorers; Barrow's *History of Voyages to the Arctic Regions* (2 vols. 1818 and 1846); C. R. Markham's *Threshold of the Unknown Region;* A. R. Markham's *Life of Franklin; Edinburgh Review*, April 1891; *Journal and Proceedings, Roy. Geo. Soc.;* and the published narratives of the various Arctic and Antarctic explorations.
